EVOLUTIONARY RELATIONSHIPS OF MHC GENES

Cause and effect in global climate change

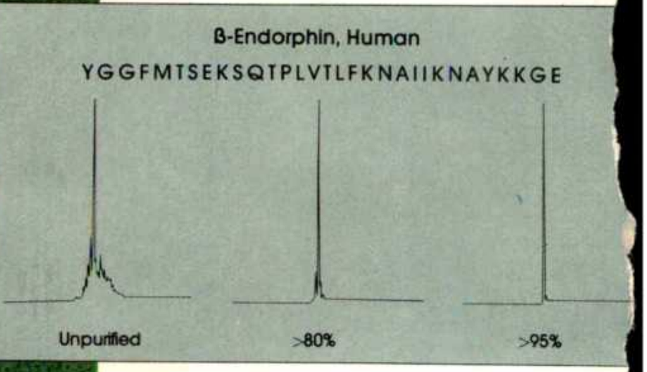
Cloning the homeotic plant gene *agamous*

CHROMATOGRAPHY/HPLC

NOW Purified Peptide

MPS specializes in quality, custom peptide synthesis . . . so you don't hav

In order to meet the differing needs of individual researchers, we are now offering three grades of peptides: unpurified, >80% purity and >95% purity. Additionally, for those using peptides to raise anti-peptide antibodies, MPS also provides a peptide carrier conjugation service. Call us with your questions or if you would like a complete price list.



COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

		Guaranteed Purity Level	
	Unpurified	>80%	>95%
Quantity	50-100 mg	30-50 mg	20-30 mg
10 mer	$400	$700	$1000
15 mer	$550	$850	$1150
20 mer	$800	$1200	$1600

CAN YOU SYNTHESIZE & PURIFY PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, purification, waste disposal, laboratory space, downtime and, of course, the initial cost of the synthesizer.

Multiple Peptide Systems

10955 John Jay Hopkins Drive, San Diego, CA 92121 USA

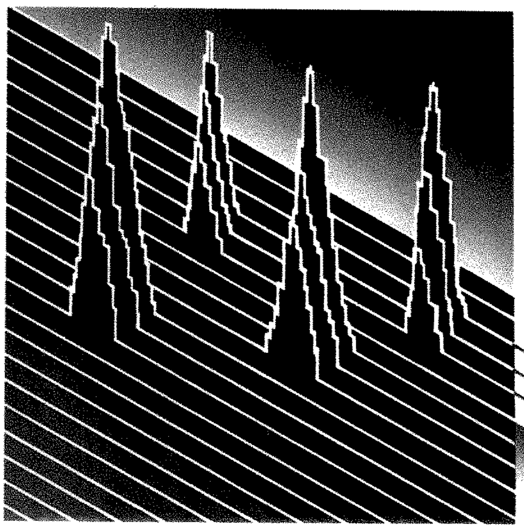
RAD^{125}IO^{14}CHROMATOGRA^{32}P^{3}HY



It all started, 25 years ago, with the legendary Berthold TLC-scanner. Today, Berthold maintains its leadership in the radiochromatography field with such outstanding instruments as

- the Linear Analyzer for one- and two-dimensional TLC-plates, gels, blots and receptor assays, and filter mats from cell harvesters
- the truly two-dimensional Digital Autoradiograph with unrivalled sensitivity
- the advanced on-line HPLC Radioactivity monitors with optimum sensitivity and resolution

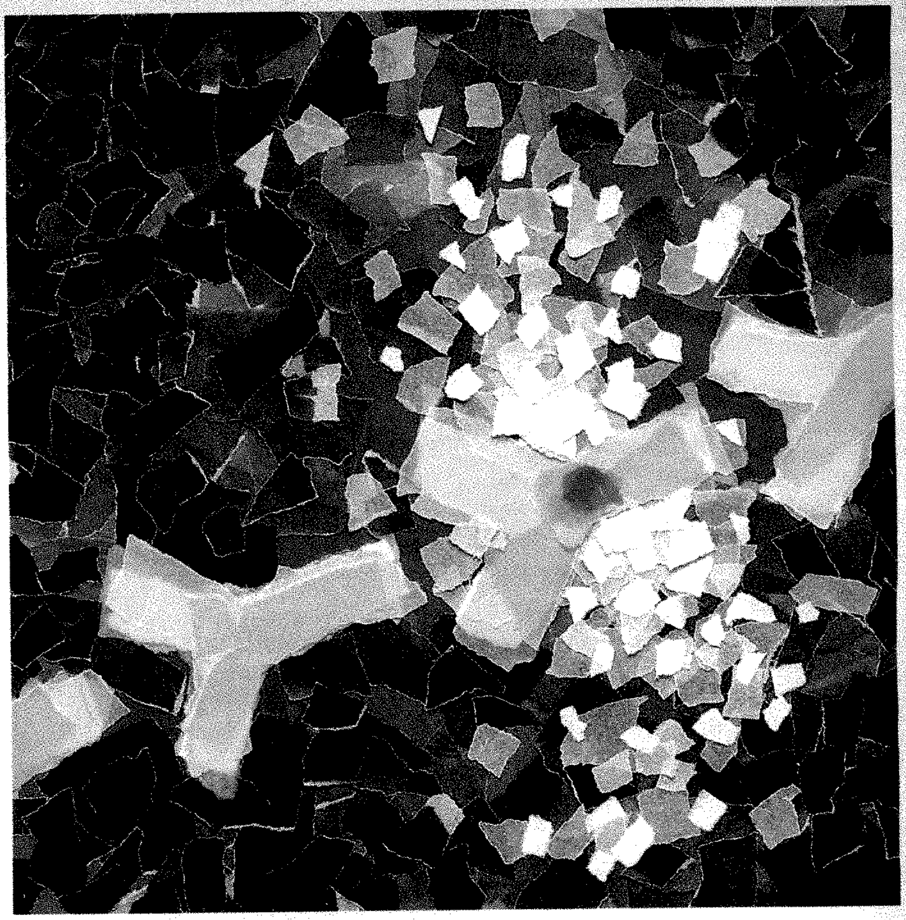
ECL



Light-based detection for Western blots

Trying to choose between ^{125}I, colorimetric and other non-radioactive systems?

With the new ECL Western blotting system, which complements our other systems, we can now help you choose the technology, radioactive or non-radioactive, to best suit your experimental needs.

The ECL (enhanced chemiluminescence) system is based on using horseradish peroxidase labelled second antibodies, or biotin-streptavidin systems.

In the presence of the ECL Western blotting detection system an enhanced light signal is created.

- 10 times as sensitive as colorimetric systems
- Results in minutes, often seconds
- Economical use of primary and secondary antibodies
- Simple protocols
- Carry out normal blotting and immunodetection techniques and then add ECL detection system for 1 minute
- No fading of results; hard copy results on film

ECL Western blotting detection system RPN 2106
(sufficient for 4000cm^2 of blots)

nature

5 July 1990

Vol. 346 Issue no. 6279

◀ The cotton-top tamarin is the most endangered primate in Colombia today. Endemic to northwest Colombia, an area of severe tropical rain forest destruction, the current population is between 300 and 1,000, though there are over 1,500 cotton-top tamarins in captivity. Study of the tamarin has thrown light on evolution of the immune systems of primates. Pages 60 and 17.

THIS WEEK . . . THIS WEEK . . . THIS WEEK . . .

On the rise

The conventional view that the high altitudes of most mountain ranges are the result of rapid late Cenozoic uplift, which in turn influenced the climate, is challenged in this week's Review Article. Molnar and England argue that global climate change may have preceded and helped cause the uplift. Page 29.

Genes in thrale

Agamous is a homeotic gene of the plant *Arabidopsis thaliana* (thrale cress): mutations of *agamous* cause transformation of stamens into petals, and replacement of carpels by a new flower. This gene has now been cloned and the sequence of its product reveals strong similarity to a class of DNA-binding regulatory proteins found in eukaryotes from yeast to man, and also the flower homeotic gene *deficiens* of *Antirrhinum*, mutations of which cause a different set of transformations. Pages 35 and 19.

Heated atmosphere

Lines of the bacterium *E. coli* maintained at an elevated temperature show rapid increases in fitness suggesting that at least some biological systems can adapt quickly to environmental change. Pages 79 and 15.

Where there's smoke

A 46-day study of a submarine thermal vent — a black smoker — reveals a remarkable temperature stability at 353±2 °C in the main flow of the hot spring, but a peak of 405 °C locally. These findings bear on a hotly debated topic, the temperature of fluids at depth beneath the sea floor. Page 51.

Yes to NO

Nitric oxide is not only the endothelium-derived factor that relaxes arterial smooth muscle but also the factor that causes hyperpolarization of the muscle, despite claims that a distinct substance is responsible. Page 69.

Prints of darkness

Cosmic ray sources, including the powerful γ-ray source Geminga, could be lumps of annihilating dark matter, according to the model proposed on page 39. The hypothesis that the free electrons that cause dispersion of pulsar signals result mainly from the decay of dark matter in our Galaxy is put to the test on page 40.

Pulsar triptych

The discovery of two new radio pulsars, the second and third in the globular cluster M15, suggests that there may be a large population of these objects, which may therefore be powerful indicators of the dynamics and evolution of globular clusters. Pages 42 and 12.

Body building

The *Krüppel* gene plays an important part in the development of the segmented body pattern of *Drosophila*, and the product of the gene has now been found to be able to 'actively' repress transcription. Page 76.

Anticlotting mechanism

Transgenic mice expressing the human gene for plasminogen inhibitor-1 develop venous occlusions, suggesting that the fibrinolytic activity of plasmin is continuously required to prevent fibrin deposition in veins. Page 74.

Hier et maintenant

Hulton

General de Gaulle, in his June 1940 BBC broadcast to the Free French. "Men of science" were also solicited to join the cause. See Then and Now.

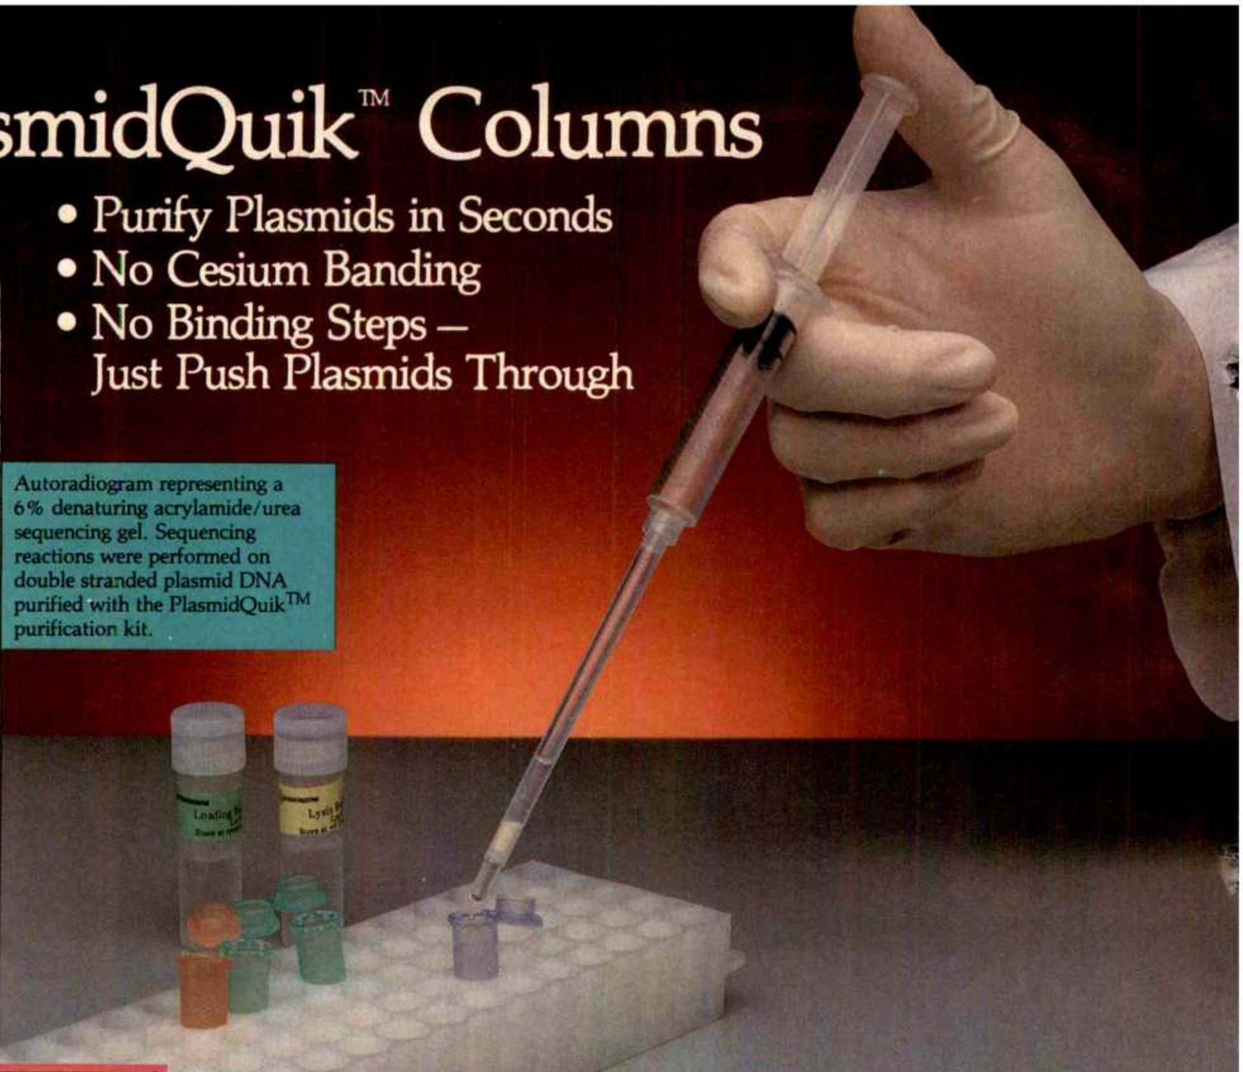
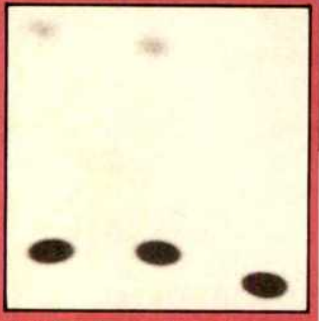
PlasmidQuik™ Columns

- Purify Plasmids in Seconds
- No Cesium Banding
- No Binding Steps – Just Push Plasmids Through



Autoradiogram representing a 6% denaturing acrylamide/urea sequencing gel. Sequencing reactions were performed on double stranded plasmid DNA purified with the PlasmidQuik™ purification kit.



Autoradiogram representing a CAT Assay/TLC Plate. COS-7 cells were transfected with 400 ng DNA purified with the PlasmidQuik™ purification kit (lane 1); 400 ng cesium banded DNA (lane 2); no DNA (lane 3). Cell transfections and the CAT assays were performed according to Stratagene protocols.

The Fastest Plasmid Purification Columns Available.

Stratagene has extended its push column technology to plasmid purification. Unlike most ion-exchange purification methods that require a binding step and an elution step, PlasmidQuik™ columns trap unwanted chromosomal DNA, RNA, and proteins but allow supercoiled plasmids to pass right through. Plasmids can be purified in seconds!

PlasmidQuik™ columns yield plasmid preparations of a purity that rivals two cesium banding steps. Procedures such as subcloning, restriction mapping, sequencing, kinasing, in vitro mutagenesis, PCR, cellular transfections, and transformations can be performed as reliably as with cesium banded plasmids.

Kits contain 25 or 50 columns and an adequate supply of lysis and running buffer.

Catalog# 400725 25 Columns
Catalog# 400726 50 Columns

Ethidium bromide stained, UV transilluminated 1% agarose gel of boiling mini-prep DNA (lane 1) and PlasmidQuik™ column purified DNA (lane 2).

Pulsed amperometric detector
Dionex CarboPac™ PA-1 column

For the first time, you can tame glycoproteins with ease. Until now, you've probably resisted the challenge of oligosaccharide mapping and profiling. And no wonder. What scientist has months and years to spare?

Now your way is clear to examine glycoproteins from initial purification to final analysis—including oligosaccharide mapping. It can all be accomplished on a single instrument. The Dionex BioLC™ System. Not in months, but in hours.

After you've done your mapping, use Dionex OligoStandards™ for fast and easy identification of the oligosaccharides you're investigating.

Find out how Dionex can make all aspects of glycoprotein analysis not only possible but, for a change, practical as well.

For complete information on how we can make a difference in your research, contact your local Dionex representative or (in U.S.A.) call **1-800-227-1817, ext. 42** today.

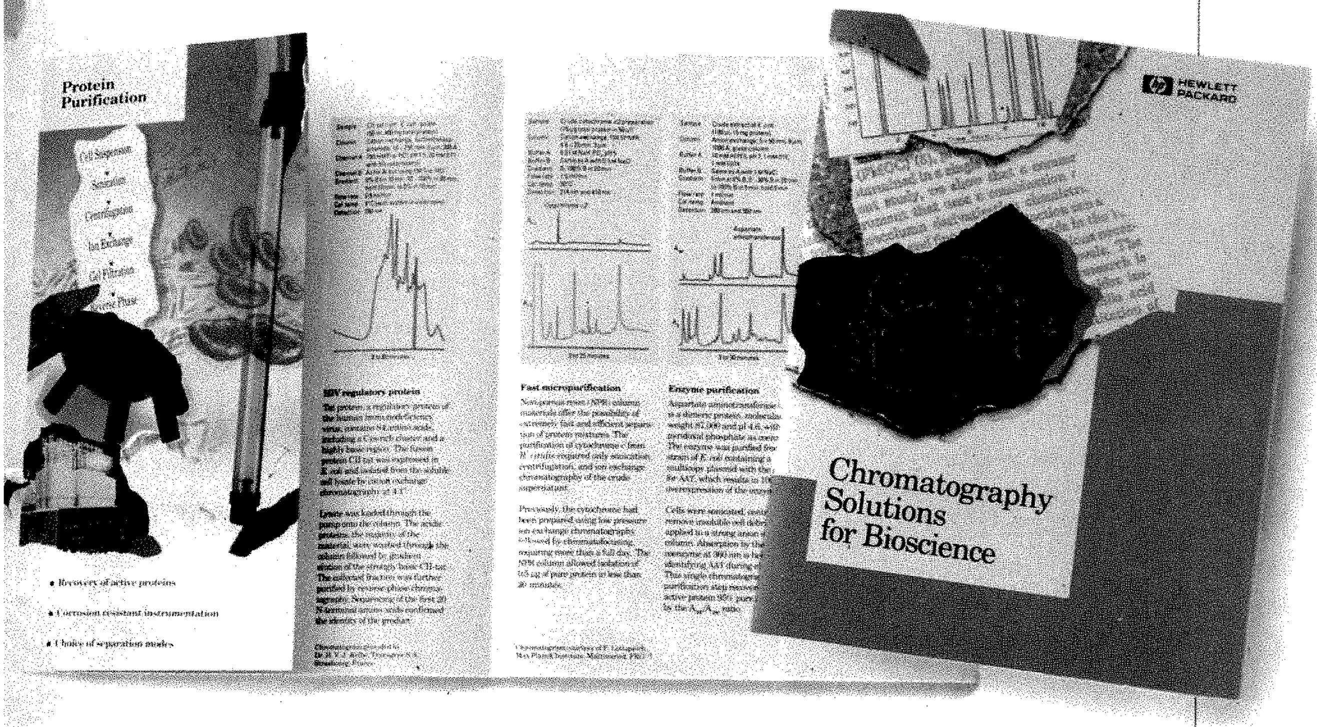
"The best material for protein separations is glass. Or stainless steel. Or titanium."



Protein Purification

Chromatography Solutions for Bioscience

HEWLETT PACKARD

The best choice may not be easy. Our free 20-page booklet, *Chromatography Solutions for Bioscience*, demonstrates that the best material for protein separations depends on several factors. Like the task you want to accomplish. And the type of proteins you're separating.

But there's more. The booklet illustrates our considerable contributions to the separation sciences over the past 15 years. Advances that have helped thousands of leading bioscience researchers achieve results they could trust. Over a wide range of applications. Proteins, peptides, amino acids, nucleic acids, nucleotides and carbohydrates, to name a few. All backed by HP's number one-ranked quality, reliability, service, and support.

For more information, contact the Analytical Department of your nearest Hewlett-Packard sales office, or our Marcom Operations Dept., Hewlett-Packard, P.O. Box 529, 1180 AM Amstelveen, The Netherlands.

Presenting the latest techniques and applications for the most promising therapeutic monoclonal antibodies

Coming Soon

Therapeutic Monoclonal Antibodies

Edited by C.A.K. Borrebaeck, D.Sc., *University of Lund, Lund, Sweden* and J.W. Larrick, M.D., Ph.D., *Genelabs, Inc., Redwood City, CA*

As commercial production of therapeutic monoclonal antibodies becomes a reality, researchers and scientists require accurate, up-to-date information to keep abreast of this rapidly moving field. There are few reliable sources of information available, particularly in one convenient publication. **Therapeutic Monoclonal Antibodies** fulfills the need for a single reference covering the latest advances in both preclinical and clinical work on monoclonal antibodies. Written by an international team of leading experts, this exhaustive work details the latest progress made in the clinical application of monoclonal antibody technology.

CONTENTS & CONTRIBUTORS:

NATURE VOLUME 1 NUMBER 1

First published Thursday, November 4, 1869

NOW available as a high quality facsimile, the first ever issue of **Nature** containing among others J. Norman Lockyer's famous article *'The Recent Total Eclipse of the Sun'*, a report on science teaching in schools in 1869 and *'Triassic Dinosauria'* an absorbing report by T.H. Huxley.

This fascinating issue makes a highly original gift and an interesting addition to your own collection. To obtain your copy simply fill in the form below.

To: Nature, Macmillan Magazines Ltd,
Brunel Road, Basingstoke, Hampshire RG21 2XS, UK.

Please send me .... facsimile(s) of the first issue of **Nature** at a cost per issue of ☐ UK £2.50
☐ Rest of World $25.

A New Slant On Density Gradient Separations

Introducing a new line of NVT™ near vertical tube rotors engineered for quick runs and good sample purity.

Designed for plasmid separations, these rotors are also useful in a variety of density gradient applications, such as mitochondrial DNA separations, chromosomal DNA separations and the isolation of proteoglycans.

NVT tube angles are unique: less than 10°, so run times are significantly reduced compared to conventional fixed angle rotors, but large enough so that contaminants pellet away from the bands of interest (see diagram).

The new rotor line includes the NVT 65 and NVT 90 for floor model ultracentrifuges, and the TLN-100 for the popular tabletop TL-100.

The NVT family of near vertical rotors. Only from Beckman.

For more information contact Beckman Instruments, Inc., 1050 Page Mill Road, Palo Alto, CA 94304. (800) 742-2345. Offices worldwide.

Taq Polymerase

From a small, specialist company in Cambridge comes the ultimate Taq Polymerase.

To assure you of its quality, more tests have been carried out on Cambio's enzyme than on any other, showing a virtual absence of 3′ or 5′ endo- or exonucleases. Its reliability is unprecedented and batch to batch variation is minimal. Cambio's Taq Polymerase has exceptional stability at 95° and a carefully optimised buffer system is provided free.

The price too is exceptional; it will enable you to cut costs significantly.

Delivery of your carefully packaged enzyme is by light speed courier: 4 minutes at the heart of the universe, the same or next day in the UK, or the next anywhere in Europe. Outlying stellar systems need a little more time.

Here at the centre of the universe, Cambio provides an unrivalled service to life scientists, offering friendly and intelligent information from people who really know what you are talking about. Why not call the hotline on (+44) 223 66500 to try us out?

Oh, we nearly forgot the special offer: how about a bottle of Champagne with every order of over 2,000 units? Free, from the centre of the universe.

What to pay for nuclear power?

A House of Commons committee has thrown new light on the ways in which British governments too often make bad decisions, especially where technical matters are concerned.

POOR (in both senses) Britain is paying a heavy price for the incompetence of its public administration, especially of technical matters. That is the chief message of the splendid report from the House of Commons Select Committee on Energy published last week (see also page 7). Ostensibly, the committee set out to tell why the nationalized electricity utility in England and Wales called the Central Electricity Generating Board (CEGB) should have told a public inquiry in 1987 that the price of electricity from a newly constructed pressurized water reactor (PWR) would be 3.09 pence per kilowatt-hour, and should have been quoting prices more than twice as much when negotiating with the government the terms on which it should be privatized. Readers of the report will not be better able to name a figure for the cost of nuclear electricity, but they will have a better understanding of the vacillations of government policy on nuclear energy.

It is a bizarre tale. Since 1972, the CEGB has been seeking to build PWRs, on the grounds that they could be built more quickly and would be intrinsically more economical than the gas-cooled reactors it had inherited from Britain's earlier flirtation with nuclear power. In 1979, the incoming Conservative government said it would sanction a programme to build ten PWRs over some forthcoming decade, but was then constrained by its predecessor's decision that none would be built until there had been a public inquiry. By the time the construction of the first reactor had begun in 1987, the government had also decided that the electricity industry should be "privatized". But it failed to appreciate that its nuclear policy and privatization policy might be in conflict. Now there is a gigantic muddle.

What the energy committee has most usefully done is to throw light on the casual ways in which these policies were made. The plans to privatize the electricity industry were made public in February 1988 by the then Secretary of State for Energy, Mr Cecil Parkinson, without a serious attempt to tell whether they were feasible. On the generating side, CEGB was to be split into two parts, 'Big G' and 'Little G' (now National Power and PowerGen respectively), but in the face of the CEGB's protests that nuclear power would be a problem.

So it has proved to be. First, in July last year, the government was forced to concede that the older gas-cooled reactors would have to remain in public ownership: reactors nearing the ends of their lives, but saddled with huge liabilities for decommissioning, would hardly have been an attractive investment. But then, last November, it had to go the whole hog, and lump all nuclear generating capacity into a third company, called Nuclear Electric, that will remain in public ownership.

The fascinating argument between the CEGB and the government, now revealed, about the price of nuclear electricity has been a proxy for the Department of Energy's failure to understand what privatization would entail. Should the discount rate (the notional cost of money) be 8 or 10 per cent? Is it surprising that CEGB, when told to ask British Nuclear Fuels (ironically, publicly owned) for a fixed price for reprocessing fuel, should be quoted a price 30 per cent greater than expected? Or that the CEGB should want to amortize new reactors over 20 years (rather than the full 40 years of life expected) to allow, in part, for the political risks ahead? In the end, the government took the view that the CEGB was asking for too much, and said no.

This sorry sequence of events may have permanently queered the pitch for nuclear power in Britain, and will also have played havoc with the public accounts. Nuclear Electric will operate existing reactors with the help of a subsidy collected from electricity consumers and called a Fossil Fuel Levy. (Britain will thus be the first industrialized country to have a carbon tax.) The Energy Committee is right to demand that the fixing of this charge should be transparent. Further nuclear construction has been postponed until a review in 1994. The Energy Committee is right to insist that the outcome of that review should be publicly debated before future policy is made. Meanwhile, there is a PWR half-built in Suffolk whose future is uncertain; why not finish the plant but not load it with fuel? That would avoid decommissioning costs and provide a lasting monument to four decades of mismanagement. ☐

Hubble trouble

The defects that have come to light in the Hubble Telescope are a serious setback for research.

THERE was always a risk that the Hubble Telescope, already more than three years late, would have been lost during the tricky process of putting it into orbit. That it should turn out to be incapable of being focused accurately is not much better (see page 3). It hardly matters that there will now be a grand inquisition to tell who is to blame, or that the US National Aeronautics and Space Administration (NASA) believes that an astronaut may be able to fix the trouble in 1993. The plain fact is that a decade's work by hundreds of skilled researchers has been undercut by an elementary error. Some hope that useful science can be salvaged, but three years out of an expected lifetime of fifteen are one loss, the inevitable degradation of many Hubble instruments another.

What should happen now is what matters most. Even if there were funds in the space science budgets of NASA and the European Space Agency (a 15 per cent partner in the venture), building another Hubble and relaunching it would not serve a useful purpose. The design of the instrument has its origins more than a decade back, while something else might in any case go wrong next time. Beginning now on the design of an even better instrument might mean that there was something to show for the effort early next century, but that is a long time to wait. By then, in any case, the design and construction of terrestrial telescopes will have reached the point at which only a radically better successor to Hubble would be worthwhile.

Last week's disappointment points sadly in only one direction — that Hubble loaded too many of the research community's eggs in the same basket, and a frail basket at that. Even if Hubble had been launched successfully, the intermittency of seeing caused by the Earth's shadow and the difficulties of planning the ponderous reorientation manoeuvres of the telescope to make the best use of its expected life, however splendidly accommodated by the software engineers, are a proof that an instrument as sophisticated as this deserves a much higher orbit. But that would mean extra power for data transmission, and an even more elaborate package . . . .

It will nevertheless be disastrous if this setback means that high-resolution astronomy from orbit is now abandoned, or postponed until after 1993. Low-resolution satellite astronomy in other than the visible regions of the spectrum has been a great success. The forthcoming ROSAT X-ray telescope will have greater resolution than its predecessors, though it has been much delayed. But there is an urgent need for complementing ground-based observations in the visible region with greater resolution from beyond the atmosphere. The need is for much simpler instruments in which versatility and optical speed are sacrificed for resolution and which are, perhaps, designed to answer predetermined questions. One virtue of instruments in orbit is that their users are not forced to hurry. They can sit there for days on end, collecting light from single objects. It would not be out of order that some imaginative agency should seek to lift the present gloom by running a competition for sufficiently robust designs. After recent experience (not only of Hubble) they should be capable of being launched by old-fashioned rockets, not through the bottleneck of the shuttle, which has now been thoroughly discredited. □

Himalayan clouds

The expedition to test Professor V. J. Gupta's claims is in doubt; Chandigarh should take other steps.

THE Panjab University of Chandigargh should not be too disconcerted that Professor V. J. Gupta has been taken ill and that the expedition he was to lead to some of the disputed fossil-sites in the Himalayas will probably not now set off in the next few weeks. Gupta's inability to travel has understandably prompted other members of the proposed expedition to say they will not go either. But the notion of testing the veracity of a whole corpus of Himalayan palaeontology by collecting fresh material from places and strata nominated by Gupta was never a particularly good one, anyway, at least without much more careful preparation than the proposed expedition had been given.

The essence of the doubt cast on much (not all) of Gupta's work is that some of the fossils he has described are unlikely to have come from the places in which he said he found them. Verification is complicated by the vagueness of the descriptions of locations in the published reports. (Sadly, Gupta is not the only palaeontologist to have erred in that respect.) A well-planned expedition would have begun with an attempt, independently of Gupta, to identify a few among the disputed fossils for which verification could be expected to be at once feasible, straightforward and in some sense clinching. Then the expedition would have known what it was looking for and, broadly speaking, where. It would not have been a particularly comradely expedition, of course; Gupta, ostensibly the leader, would have felt an uncomfortable pressure to deliver the goods under the eyes of watchful, even sceptical companions. But in the event, very little thought seems to have been given to the planning of the expedition except that it should set off some time this northern summer.

Dr R. P. Bambah, the vice-chancellor at Chandigarh, has rightly said that he wants neither a "witch-hunt" nor a "whitewash". No scientist whose work has been as seriously questioned as has been Gupta's deserves less of his university. But there are simpler procedures on which the university could and should fall back. By now, there have been such specific complaints against some of Gupta's conclusions that an expedition of verification need travel no further than his laboratory. Some of the disputes that have arisen could probably be settled if Gupta were asked to furnish a group of independent palaeontologists with original specimens (or to explain why they do not exist). The question is not whether there are, for example, conodonts in some Himalayan formations, but whether Gupta's past published reports of them are sustained by the evidence. Going off to the mountains is neither a necessary nor a sufficient test of that. What Chandigarh must recognize is that its own reputation will suffer from further delay. □

Hubble Telescope has misshapen mirror

■Non-imaging work to be emphasized ■Corrective lens by 1993?

Washington

The Hubble Space Telescope (HST), its builders have proudly claimed, contains the most precise optical system ever made, with reflecting surfaces polished to an accuracy of less than one-fiftieth the wavelength of light. That claim is still true.

But unfortunately, as officials of the National Aeronautics and Space Administration (NASA) admitted last week, the optical system was precisely made to the wrong shape, making HST's resolving power the same as that of the best ground-based telescopes, not ten times better.

But HST astronomers are confident that much of the science programme can be salvaged, and the defect is simple enough that replacement cameras equipped with corrective lenses, which could be installed by a space shuttle crew three years from now, will restore HST's full acuity.

The flaw was discovered as NASA engineers began to adjust the position of HST's secondary mirror, a small convex mirror that reflects light from the 2.4-m concave primary into the scientific instrument package. By shifting the secondary up and down the axis, astronomers expected a stellar image to come into perfect focus.

But the image could not be focused, and analysis of the way it changed as the secondary was moved indicated that HST suffers from spherical aberration caused by a departure of the radial profile of one of the mirrors from the required shape. The defect was such a "textbook example", according to deputy project manager Jean Oliver, that it must have been ground into the mirror during manufacture.

The departure of the optical surfaces from the required shape is small — about half a wavelength of light — but enough substantially to reduce the image quality (see below).

Most planned HST observations requiring high-resolution imaging will be put aside, but NASA officials were anxious, when announcing their predicament last week, to emphasize the "unique and important" science that HST can still do. Project scientist Ed Weiler pointed out that three of the HST instruments, the high-speed photometer, the high-resolution spectrograph and the faint object spectrograph, are non-imaging devices and had been expected to do much of their most significant work in ultraviolet regions of the spectrum, which are inaccessible from the ground.

The loss of resolution means that observations of faint, finely detailed objects will generally not be feasible, and HST managers will replace such observations with proposals that had been turned down for lack of available time.

Weiler, along with deputy project manager Jean Oliver, was hopeful that HST's spherical aberration can be so exactly diagnosed that it will be possible to design a simple corrective lens to restore HST's full ability. An improved Wide Field/Planetary Camera is in fact already partly built, and with corrective lens added could be installed during a scheduled shuttle flight as early as June 1993.

The same can in principle be done for the Faint Object Camera, but Peter Jakobsen, HST project scientist for the European Space Agency (ESA), which provided the camera, said that no specific plans could yet be made.

While astronomers were mostly interested in finding remedies, NASA is setting up a review panel chaired by Lew Allen, director of the Jet Propulsion Laboratory, to determine the cause of the defect. Oliver was adamant that HST's optical design was correct, and Bob O'Dell of Rice University, who chaired a space telescope planning group in the 1970s, agreed that the design had been checked by so many people that any possibility of a flaw had been eliminated. The error, Oliver concluded, must therefore have been in the mirror testing procedure.

The primary and secondary mirrors were never tested in combination. According to Oliver, a test of the optical system of HST would have required the construction of an optically flat surface as big as the primary; the cost would have run into hundreds of millions of dollars. Instead, the two mirrors were separately tested for conformity to the desired profile. Somehow, during the manufacture and testing, one of the mirrors was made to the wrong shape, and it will be the job of the review panel to discover how an error that should easily have been caught remained hidden until three weeks ago.

That job may not be easy. HST's mirrors were completed in 1981, and few of the people now involved in the project have any connection with those early days.

When NASA put construction of the HST optical system out for bids, the Perkin-Elmer company, an experienced builder of high quality optics, sent in a proposal that included a detailed account of how the optical surfaces would be separately finished to NASA's specifications. Although, as O'Dell recalls, some astronomers at the time would have been happier with an integrated test of the optics, Perkin-Elmer's proposal was judged adequate to the task.

Perkin-Elmer (now Hughes-Danbury after a take-over) won the contract and built the mirrors, but project managers at NASA's Marshall Space Flight Center (MSFC) in Huntsville, Alabama, had responsibility for ensuring that the terms of the contract were fully carried out. The review panel will reconstruct what happened both at MSFC and at Perkin-Elmer to find out how the faulty mirrors passed muster at both places. **David Lindley**

...and the good news

The optical system of the Hubble Space Telescope was designed to put about 70 per cent of the light from a point source into an image spot 0.1 of an arc second in diameter. Atmospheric turbulence prevents the best ground-based telescopes from producing images smaller than about one arc second.

A photograph made on 20 May by HST's Faint Object Camera (FOC) resolved stars into a central bright spot less than 0.1 arc second across and containing about 20 per cent of the light, the remainder being spread across a one arc second disc. It now turns out that FOC's first shot is as good as it will get.

At first, NASA officials and astronomers emphasised HST's capacity to do non-imaging photometry and spectroscopy, especially in the ultraviolet, where HST's chief advantage is simply to be above the Earth's atmosphere. But in the days following the announcement of the flaw, some have become more optimistic.

Peter Jakobsen of the European Space Agency, which built the FOC, says that because HST's images have a prominent core surrounded by a fainter halo, images of high-contrast objects, such as densely packed stars at the centre of globular cluster, will still be informative. And the fact that HST's distortion is of a constant, wavelength-independent form means some computer image-reconstruction techniques may be useful.

On the other hand, HST will not be able to see extended objects of low surface brightness any better than ground-based telescopes. It had been hoped, for example, that the FOC would be able to photograph the faint galaxies in which distant quasars are thought to reside, but Jakobsen now thinks the quasar light that spills into the one-arc-second halo will overwhelm any galactic light that might be there.

Nevertheless, Jakobsen thinks NASA was too "downbeat" in saying that virtually all the imaging work of HST will be useless, and emphasized that it is "early days" for astronomers thinking of ways to compensate for HST's deficiency. **D.L.**

COMETARY PROBE

Giotto steals a ride

Munich

THE Earth lost a minute fraction of its orbital velocity earlier this week as the European Space Agency (ESA) Giotto space probe stole a little of the Earth's energy to help it on its way to a rendezvous with the comet Grigg Skjellerup. It was the first time the manoeuvre, the same "gravity assist" that helped the NASA Voyager probe on its journey from Jupiter out to Saturn and Neptune, had been executed using the gravitation field of Earth. According to ESA researcher Trevor Morley, Giotto will gain 3.1 km/sec in velocity, meaning that the Earth will slow in its orbit by one millimetre in every million centuries.

A free ride on the Earth's gravity was a welcome break for a project that is beset by funding uncertainties. Despite the tremendous success of the original Giotto mission to Comet Halley in 1986 (see *Nature* **320**, 202 & **321**, 259; 1986) and the potential for further cometary exploration, ESA voted last month to make the Giotto Extended Mission (GEM) an optional, not mandatory, project within its science programme. Member states will meet in September to discuss whether they are prepared to pay for Giotto.

Project manager Manfred Grensemann at the ESA ground station in Darmstadt is "optimistic" that enough support can be found. He estimates that the next phase of the mission would cost 10 million ECU (about $8 million), mostly for the communications needed to keep in touch with the probe as it moves farther away.

"Compared to starting a new mission, this is a bargain", says GEM project scientist Gerhard Schwehm. Schwehm said that the second flyby would be a unique opportunity to expand knowledge of comets. It will be especially interesting, he said, to study the interaction of the coma of the comet and the solar wind, as well as to compare the distribution and optical properties of dust around Comet Grigg Skjellerup with that around Comet Halley, which had at least 100 times more of it.

Giotto was one of five spacecraft to approach Comet Halley in 1986, but it moved far closer than the others and came away with dazzling photographs of the nucleus. After the Halley encounter, Giotto was put into 'hibernation' to conserve power as researchers sought a suitable second comet to study with the craft. The probe will now be put into hibernation again until May 1992, when it will 'awaken' and prepare for the next encounter.

Unfortunately, said Grensemann, the camera that took the dramatic shots of the nucleus of Comet Halley is no longer operating — the sensors still function but no light reaches the aperture. But seven other instruments on board are at least partly operational and Grensemann expects them to deliver good data.

The researchers chose Comet Grigg Skjellerup as Giottos's target as much for practical as for scientific reasons. The comet was in a position in its orbit around the Sun that meant only minor adjustments in the trajectory of Giotto were needed for them to meet.

RHEUMATOID ARTHRITIS

New institute for Berlin

Munich

A RESTORED villa on the Kleiner Wannsee, a lake within West Berlin city limits, will become home for a new institute for research into the causes of rheumatoid arthritis. Immunologist Avrion Mitchison of University College, London, has been named as scientific director and will work in Berlin half-time.

As a result of a political squabble over the institute between the left-wing coalition of Social Democrats and Greens which took office last year in West Berlin and the Conservative Christian Democrats who begin the project, the institute will study not only the molecular biology of the disease but will also look at "psychosocial factors" that contribute to its development. Mitchison says that this area has been neglected in rheumatoid arthritis, especially in comparison to the attention it has received in cancer.

Steven Dickman

CONFERENCES

Changes at Dahlem

Munich

SILKE Bernhard, scientific director of the Dahlem Conferences, is to step down because of ill health. A physician by training, Bernhard had been credited by participants with building the high international reputation of the conferences.

Last year, Bernhard struggled to maintain the conferences when their original backer, the 'Donors Association for Promoting Arts and Sciences in West Germany' (*Stifterverband für die Deutsche Wissenschaft*) withdrew its support. The Free University of Berlin took over sponsorship in November (see *Nature* **340**, 86 & **342**, 466; 1989).

Jennifer Altman, a neuroscientist and formerly on the staff of *Nature*, will act as interim scientific director until an international search can be arranged for a permanent director.

Steven Dickman

JAPANESE UNIVERSITIES

Murmurs of complaint

Washington

JAPAN's national university professors are all employees of the government, which puts them in an odd position when they want to protest to the government about university conditions. But last month, the Association of National Universities finally succeeded, after years of trying, in winning funds from the Ministry of Education, Culture and Science to set up a committee to study their own financial difficulties.

The association represents all the 93 national universities directly supported by the government and has responsibility for setting up the general entrance examination.

Akito Arima, president of the association and of the University of Tokyo, recently described the universities' difficulties in a magazine of the Ministry of Finance. "In Japan about 1 per cent of GNP is allocated to college education and research, but in the United States it is 1.5 per cent. Within the limited budget, priority is placed much more on building new laboratories, moving universities, and big science, and less on the reconstruction or the maintenance of existing laboratories.

"As a result, buildings and equipment are becoming old and dilapidated. Good research cannot be produced by laboratories that are too small and lack both good equipment and money. We must find other financial sources." The new committee has not decided its plan of action and will first gather basic data.

ANTARCTICA

Airstrip plans on ice

Sydney

AUSTRALIA has been forced to abandon plans to build an 'environmentally friendly' A$1 million airstrip close to its Casey Base in Antarctica. The experimental runway was built on ice to minimize the effect on wildlife, most of which lives on the very small part of the Antarctic that is rock. Construction of a rock runway at the French Antarctic base led to an international outcry as Greenpeace claimed that an important breeding ground for Adélie penguins had been destroyed.

But ice has not proved to be safe after all, according to a report by the Royal Australian Air Force. Last summer, the report says, a vehicle broke through the ice on the runway and sank into the water beneath. Because of the risk of the runway melting and breaking up, the air force argues that a gravel airstrip should be built.

The Australian Department of the Environment's Antarctic Division has proposed an alternative site for an ice and snow runway 30 km away from Casey where the climate is harsher. The United States has a successful ice strip at its McMurdo base south of Casey.

Tania Ewing

CHEMICAL WEAPONS

First test of incineration

Boston

IF all goes as planned this week, the US Army will destroy by incineration a first batch of chemical weapons at its new facility on remote Johnston Island in the Pacific Ocean. The trial incineration, which the Army calls "operational verification testing", is the first step in fulfilling the agreement between US President George Bush and Soviet President Mikhail Gorbachev earlier this year to destroy the bulk of the superpowers' vast chemical arsenals (see *Nature* **345**, 192; 1990).

Although the chemical weapons agreement was widely welcomed, both sides acknowledge that destroying the weapons presents environmental dangers that could engender considerable political opposition. On the US side, the Johnston Island facility represents the US Army's attempt to show that the ageing chemical weapons can be disposed of safely. The incinerator was completed last year, before the recent agreements, to destroy a large stockpile of chemical weapons that had been stationed in the Pacific during the Second World War. These weapons, amounting to several thousand tons, have been stored since 1971 on Johnston Island, which is some 700 miles from its nearest Hawaiian neighbour.

Army chemists say that because the chemical components of the nerve, mustard and blister agents to be burned are known so precisely, and because of the facility's state-of-the-art design, it should generate fewer toxic emissions than conventional trash incinerators. But this optimistic view is not universal. Dozens of environmental groups have objected to the facility during the lengthy political process required for it to open, decrying the potential air pollution and toxic solid wastes generated by incineration and favouring alternative disposal methods.

Even as testing begins, Sebia Hawkins of Greenpeace says that there is "still hope that the facility can be stopped". But environmentalists concede that the Army has largely sidestepped opposition because the island is so remote and lacks a native population. Future incinerators to handle the vast bulk of the nation's stockpiles remain to be built, and are likely to generate far more political opposition.

Almost everyone involved in the project admits that a deadly accident could occur. As carefully designed as the handling procedures are, the sheer scale of the operation is worrying.

The Johnston Island facility will handle thousands of tons of lethal chemicals — some of which can kill in microgram quantities — and burning all the chemical agents now stored on the island is expected to keep the incinerator running steadily for over a year.

Adding to the controversy is the fact that later this year another 430 tons of chemical weapons are scheduled to arrive at the island. The new intake comes from West Germany in the wake of an agreement in 1987 between then US President Ronald Reagan and German Chancellor Helmut Kohl that the United States would remove its chemical stockpile from German soil. The agreement stipulates that the weapons must be removed by the end of this year, but does not specify where they should go. Johnston Island is virtually the only place in the world that can handle them, so the plan is that the weapons will be moved by truck, rail and ship, under tight security, from Clausen, Germany, to Johnston Island.

All told, the Johnston Island facility is marked for the incineration of less than 7 per cent of the US stockpile. The current plan calls for the other 93 per cent to be incinerated in the continental United States, at military facilities in Alabama, Arkansas, Colorado, Indiana, Kentucky, Maryland, Oregon, and Utah. Public opposition is already mounting.

Meanwhile, the Soviet chemical weapons stockpile is said to be even larger than that of the United States, and the Soviet destruction programme is in its infancy. The Soviet president has asked for US help with the Soviet effort to destroy chemical weapons, and collaboration is written into the formal agreement between the two countries. Elisa Harris, an expert on chemical and biological weapons at the Brookings Institution in Washington, says that the Soviet population has even less confidence in its government's ability to do the job than Americans have in the US chemical weapon destruction programme.

She calls the domestic Soviet problem part of a "post-Chernobyl syndrome". The political controversy generated in both countries is likely to make Johnston Island an important model for both sides. US experts have met already with Soviets in Geneva and Moscow to discuss technical issues of chemical weapon destruction, and a Soviet delegation is expected soon to visit a small-scale prototype US facility constructed several years ago at an Army base in Tooele, Utah. As Harris puts it, "the Soviets are clearly capable of destroying their own chemical weapons", but with the domestic political difficulties involved in carrying out such programmes in either country "it will be interesting to see just how much cooperation each side has in mind".

CONSERVATION

Tigret spells hope for endangered species

Washington

THE world's first test-tube tiger was put on display at the National Zoo in Washington DC last week. Although the cub was born two months ago, zoo officials have up until now not had the confidence to show it to the public. Two other cubs born at the same time died in their first weeks.

Jeff Tinsley, Smithsonian Institution

Test-tube baby — the world's first IVF tiger.

The cub, named Mary Alice, represents a $2 million dollar investment in *in vitro* fertilization (IVF) technology which the zoo hopes will help to preserve endangered species. Mary Alice is a Siberian tiger, a rare subspecies of tiger of which only 200 remain in the wild. Seven hundred are kept in zoos around the world, which means that captive breeding provides the best chance of saving it from extinction.

The IVF technique is likely to be of particular help because it allows sperm from a valuable male in one country to be used to fertilize eggs from a partner in another country, without all the difficulties of transferring the animals themselves.

Since 1984, the National Zoo, in co-operation with Henry Doorly Zoo in Omaha and the Minnesota Zoo, has being working to adapt IVF techniques originally developed for humans. After IVF was used successfully with domestic cats, the technique was tried on the Siberian tiger. Three test-tube cubs were born in Henry Doorly Zoo on 27 April. A mobile IVF laboratory developed by the National Zoo and taken to Omaha for the placement of the three fertilized eggs in the surrogate mother tiger will provide artificial breeding technology to other zoos in the future.

MONTREAL PROTOCOL

Warming to global agreement

London

UK Environment Secretary Chris Patten hailed last week's Montreal Protocol meeting in London as "a major step forward in environmental diplomacy", after participants agreed to phase out ozone-depleting chemicals more quickly than agreed at Montreal in 1987 and both the Indian and Chinese delegations said they would urge their governments to join the protocol.

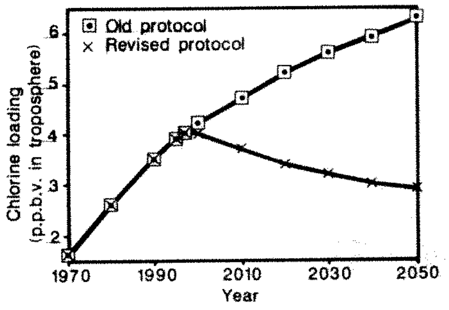
The involvement of India and China, which both have the potential to develop large chlorofluorocarbon (CFC) industries, was in doubt until the United States withdrew demands that it should have control over an international fund to help developing countries finance alternatives to CFCs, in proportion to its 25 per cent financial contribution.

Under the 1987 Montreal Protocol, CFC use was to be halved by 1998, and halon use was to be frozen at 1986 levels in 1992. The new protocol has CFCs phased out altogether by 2000, following a 50 per cent cut by 1995 and an 85 per cent cut by 1997. Halons are also to be eliminated by 2000, except for some essential firefighting uses, following a 50 per cent cut in 1995.

Carbon tetrachloride and methyl chloroform, not covered by the 1987 protocol, are also to be phased out, by 2000 and 2005 respectively. Although these chemicals damage ozone less than CFCs and halons, they are used widely in industry.

Many nations pushed for even quicker progress, and near the conference's end, a 13-nation breakaway group led by Finland announced that its members would end their use of CFCs by 1997, irrespective of the final form of the protocol. US, Japanese and Soviet opposition prevented the conference adopting the 1997 target date, although the target will be reviewed again in 1992. Patten said that the United Kingdom, while not among the 13, would aim to eliminate CFC use by 1997, except for medical uses where alternatives are not yet available.

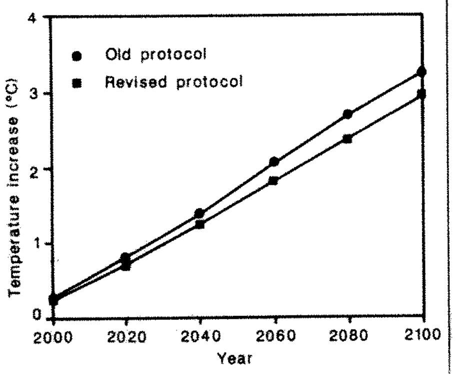
Scientists at the UK Department of the Environment have produced a preliminary analysis of the effects of the new protocol on atmospheric chlorine loading (see figure). By 2050, chlorine loading in the troposphere, at 2.9 parts per billion by volume (p.p.b.v.), will be less than half that predicted under the 1987 protocol. Chlorine loading in the stratosphere, and hence effects on ozone depletion, will lag behind this by about five years.



Joe Farman, a member of the UK Stratospheric Ozone Review Group and the discoverer of the Antarctic ozone hole, is worried that even the new controls do not go far enough. He says that the aim for the London meeting should have been to reduce atmospheric chlorine loading back to about 2 p.p.b.v. as quickly as possible. The new protocol will not approach this target until late next century, after concentrations rise to an unprecedented 4 p.p.b.v., a timetable Farman describes as "madness".

Peter Aldhous

Effects of new protocol



New controls on ozone-depleting chemicals outlined in the revised Montreal Protocol will also reduce global warming, as some of the chemicals involved are greenhouse gases. The figure shows the likely effects of the new protocol on increase in global mean temperature from the 1990 value over the next century, carried out for *Nature* by Professor Tom Wigley of the University of East Anglia.

The prediction is from STUGE (Sea level and Temperature change Under the Greenhouse Effect), an interactive microcomputer-based model developed by Wigley and his colleagues Tom Holt and Sarah Raper. STUGE incorporates models used by the Intergovernmental Panel on Climate Change working group I, and Wigley makes the key assumption that a doubling of atmospheric carbon dioxide will increase temperature by 2.5 °C.

Wigley says that his prediction includes some *ad hoc* judgements about the use of the hydrochlorofluorocarbons that are expected to replace CFCs in the short term, and stresses that the model gives a best estimate, around which there may be some margin of error.

The amended Montreal Protocol has only a small effect on global warming, reducing temperature increase between today and 2100 by only about 0.3 °C. But Wigley says: "if we're going to make any progress, it will be the sum total of small effects". **P.A.**

BIOMEDICAL RESEARCH

Young researchers go short

Washington

THE hard times being faced by young biomedical researchers in the United States were the major focus of a meeting on 'Support for Biomedical Research' held last week under the sponsorship of the National Academy of Sciences and the Institute of Medicine.

Although the National Institutes of Health (NIH)'s total funding has increased moderately over the past few years, there has been a steady fall in the percentage of successful applications in the 'new and competing' grants category — the grants that launch a young researcher on an independent career. This year as few as 22 per cent of applications are likely to be successful, down from almost double that percentage three years ago.

Many scientists now think that the problem of a shortage of funds was compounded by a decision made in 1985 by James Wyngaarden, then director of NIH, to increase the length of time for which grants run. The decision was made, in part, to provide scientists with greater financial stability and to relieve them of the inordinate amount of time spent renewing grants. But it has had the unintended side effect of intensifying competition among scientists fighting for their first grants.

Although most scientists agreed that the fundamental problem was a lack of money, David Baltimore, president of Rockefeller University, questioned whether available money was being spent efficiently. He claimed that the Howard Hughes Medical Institute, a nonprofit organization, will win a "disproportionate result" from spending just $44 million this year to support young scientists.

Industry is continuing to play a large role in biomedical research. In 1979, industry funded 29 per cent of health research and development. Last year, this had risen to 45 per cent. As industry leaders acknowledge their debt to public-sector research, Baltimore suggested that industry could do still more to help by contributing about $100 million a year to support young researchers and infrastructure development. But Senator Dale Bumper (Democrat, Arkansas), who serves on the committee that appropriates funds for NIH, said that the federal government "must take a strong lead in basic research" and not leave it to *ad hoc* corporate decisions".

Diane Gershon

UK NUCLEAR POWER

Pressurized accounting

London

THE Department of Energy, former Energy Secretary Cecil Parkinson and the now defunct Central Electricity Generating Board (CEGB) were all at fault in the abortive attempt to privatize Britain's nuclear power stations. That is the conclusion of an all-party House of Commons committee which has investigated the spiralling cost estimates for nuclear-generated electricity in the run-up to privatization of the electricity industry last year.

Michael Clark, a Conservative Member of Parliament who chairs the energy select committee, said that these costs more than doubled from CEGB estimates given in 1988. The increases forced the government last November to retain Britain's nuclear stations in public ownership, and to freeze plans to build three more pressurized water reactors (PWRs) besides that now being built at Sizewell B, in Suffolk (see *Nature* **342**, 213; 1989).

The report acknowledges that some of the cost increases, for example those due to tightened environmental safety standards, were genuine. But it suggests that the bulk of the increases reflect the fact that the CEGB had never previously provided adequate costings for nuclear generation. The report concludes that "there has been a systematic bias in CEGB costings in favour of nuclear power". Only impending transfer to the private sector forced the CEGB to account for realistically low-risk investment and high returns on capital. After being told for years that nuclear generation was cheaper than other forms of power, it is now "close to the truth to say that nuclear electricity is expensive", Clark said.

The committee censures the Department of Energy and successive governments for failing to obtain realistic nuclear costings from the CEGB. Parkinson is attacked as the minister responsible for privatization, in particular for ignoring the energy committee's advice in July 1988 — which doubted the wisdom of privatizing nuclear power and suggested the government had "glossed over" nuclear costs. But two Conservative members of the committee, Malcolm Moss and Michael Stern, distanced themselves from the attack on Parkinson at the report's launch, because the former Energy Secretary had not been able to give evidence to the committee. An earlier leaked draft of the report had been more forthright in its criticism of Parkinson, saying he had acted like a "dilettante".

The energy committee's report followed close on the heels of a rise in estimates of the cost of completing the Sizewell B PWR caused by contraction of the PWR programme. Costs that would have been shared across the four planned stations will now be borne by Sizewell B alone. The revised capital cost of Sizewell B, at £2,030 million in 1987 prices, is more than £300 million greater than the original 1987 estimate.

The environmental group Friends of the Earth (FoE), which leaked the figures last week, and opposition Labour energy spokesman Frank Dobson have called for Sizewell B to be cancelled. But John Collier, chairman of Nuclear Electric, the government-owned company that now runs the old CEGB's nuclear stations, said that this would be uneconomic, and dismissed FoE's claim that construction work is running behind schedule. Collier said Sizewell B's costs are not "largely out of control", as FoE had claimed: all the revisions were due to the cancellation of the three further PWRs.

Sam Goddard, director of construction and future programmes with Nuclear Electric, said that the cost of electricity from Sizewell B would need to be about 2.5p per kilowatt-hour in order to recover future investment that could be avoided if the project was cancelled. This is similar to the cost of electricity from a new combined-cycle gas turbine plant and less than electricity from a coal-fired station (between 3.3 and 4p per kilowatt-hour). But, if both future and past investment in Sizewell B is used to calculate costs, its electricity is more expensive than either gas- or coal-fired stations.

Clark said he believed that completion of Sizewell B was still justified. Apart from financial considerations, retaining a PWR may be useful in keeping open the option for a later expansion of UK nuclear power. This may prove necessary if 'carbon taxes' are levied on fossil fuels, or enforceable limits on carbon dioxide emissions are introduced, to counter the problem of global warming. **Peter Aldhous**

CHINESE DISSIDENT

Fang gets down to work

London

IN his first public appearance since his surprise release from China, dissident astrophysicist Professor Fang Lizhi made a short statement at the Royal Society in London last Friday. Fang looked forward to "a period of peace and quiet", in which to pursue his research, and declined to answer any political questions.

Associated Press

Fang Lizhi (left) is greeted by Sir George Porter, president of the Royal Society.

Fang has now taken up his position at the University of Cambridge's Institute of Astronomy, where he will continue his work in cosmology and large-scale structure of the Universe. Professor Martin Rees, director of the institute, says he is particularly pleased to welcome Fang, who had been extremely effective in promoting academic contacts between China and the West during the early 1980s.

The Royal Society will support Fang's research for up to a year, but Fang may eventually choose to settle in the United States. Peter Aldhous

SCIENTIFIC MISCONDUCT

Lawsuit problems

Washington

IN recent months, at least three unexpected lawsuits have introduced a wild card to the investigation of scientific misconduct. In each case, a whistle-blower has filed suit — claiming scientific misconduct — under an obscure provision of federal law that allows informants to sue for damages on behalf of the United States and to keep 30 per cent of the damages should they win. Known as a *qui tam* action, such a lawsuit is decided by a jury in federal court, effectively bypassing the scientific misconduct investigation process of the federal science agencies.

The law was designed to encourage whistle-blowing, especially in areas prone to fraud and embezzlement such as defence contracting.

But *qui tam* suits can be quite lucrative in scientific misconduct cases as well. Damages are trebled by law, and if a large National Institutes of Health grant must be repaid times three, a 30 per cent share could amount to many tens of thousand dollars. "Whistle-blowing for fun and profit", is how Crowell and Moring attorney Robert Charrow describes it.

Federal scientific integrity officials and congressional staff are watching the trend closely. "It's a real problem — the purpose of misconduct investigations is not to make anyone rich", says Greg Simon, staff director for the investigations and oversight subcommittee of the House of Representatives Science and Technology Committee. If *qui tam* suits continue, Congress may be forced to try to introduce legislation exempting scientific misconduct from the law, he says.

G. Christopher Anderson

MIT

Charles Vest is new president

Boston

After several false starts and a renewed extended search, the Massachusetts Institute of Technology (MIT) has officially chosen its new president. Charles M. Vest, a 48-year old mechanical engineer who is now provost of the University of Michigan, has accepted the job and been formally approved by the MIT Corporation, and is due to begin as MIT's fifteenth president in mid-October this year. At his first news conference at MIT, Vest bemoaned the state of US competitiveness, saying that "large segments of the nation have lost the will to excel". He pledged a "fundamental reassessment of engineering education".

Several leading contenders removed themselves from consideration, and one, biologist Phillip Sharp, declined the job a week after his selection was formally announced. Vest said he is "proud to be a colleague" of someone like Sharp who puts his research above his desire to be an administrator, and brushed aside comments about the long, tumultuous search.

Seth Shulman

JAPANESE SCIENCE

Land of rising publication

Washington

In the past decade, Japanese researchers have increased their representation in the pages of leading international science journals by over 50 per cent, according to a new survey in *Science Watch*, a newsletter published by the Institute for Scientific Information.

Organic chemistry leads the list of improved Japanese research fields, as measured by journal publication. The five leading chemistry journals recorded an increase in Japanese papers from 8.8 per cent in the first half of the decade to 11.3 per cent in the second half. Applied physics research, especially in the fields of solid state and condensed-matter physics, has been another strong area for Japanese scientists in the 1980s. Representation in top physics journals jumped from 5.1 per cent to 8.5 per cent over the decade.

Biology is the third area in which Japan has shown marked improvement in journal publication. Representation in the five leading biology journals increased from 3.3 per cent to 5.9 per cent in the past decade. But in the two leading multidisciplinary journals, *Science* and *Nature*, Japanese representation has grown only slightly. *Nature* continues to publish more than twice as many Japanese papers as *Science*: the ratio is now 1.8 per cent to 0.8 per cent, as compared to 1.6 per cent to 0.7 per cent a decade ago.

G. Christopher Anderson

UNIFYING GERMAN RESEARCH

Problems of streamlining

Munich

With the steamroller of German unification fast approaching, the East German Academy of Sciences last week began the awesome task of stripping away 14,000 of 24,000 jobs in order to create a streamlined core that can be integrated into West German science. Pressure from both the recent currency union and shrinking funds for science forced the East German government to give the academy only until the end of the year to complete its changes. Research institute directors did not learn of this decision until a meeting at the Adlershof research campus in East Berlin on 25 June.

Even the planned reduction will probably not be enough to satisfy the West Germans who will hold the purse-strings for science in a unified Germany. The number of employees who survive the academy cuts is likely to be under 10,000 — but even the renowned Max Planck Gesellschaft of West Germany has just 13,000 employees. That means that an academy with 10,000 employees may still seem excessive when the two German states are unified politically, a step now likely to take place in December. The academy will lose nearly half its budget as the industrial *Kombinate*, which provided support for contract research, disappear in the face of West German competition.

The East German Research Ministry, which is responsible for the academy in the current East German government, has promised to do its best, but is unlikely to be able to take up all the slack as funds disappear. East German Research Minister Frank Terpe said just two weeks ago that he would try to provide a two-year 'moratorium' on the closing of academy institutes to allow time for restructuring and for the influential West German science advisory council (Wissenschaftsrat) to survey academy research projects and recommend changes.

But this timetable is proving too slow for the West German Research Ministry (BMFT) which will take responsibility for the academy in a unified Germany. A BMFT spokesman says that the ministry cannot wait the 18 months requested by the Wissenschaftsrat to see which institutes and groups should survive, but would prefer a "rough assessment" to be completed by December. Though this is "not a perfect solution", he said, "we will try to push in this direction. No matter how much is required for the evaluation", he added, "money will be no obstacle." Wissenschaftsrat will have practical problems carrying out the evaluation so quickly. "It will be hard to get the experts in on short notice," warned Wissenschaftsrat chairman Dieter Simon.

West German Research Minister Heinz Riesenhuber will meet Terpe, East German Education Minister Hans Joachim Meyer and the heads of West German science organizations this week in order to try to force the pace.

The new East German scientific leaders have additional worries. Benno Parthier, just appointed director of an academy research institute in Halle and president-elect of the Akademie Leopoldina, said that such a quick change would not leave time for a "differentiated look" at what East German science could do.

Horst Klinkmann, a medical researcher in Rostock who last week became the first democratically elected president of the academy, said that if there is not enough time to adapt, it will leave a "scientific vacuum" in East Germany that could destroy the economy.

BMFT wants different institutes to receive different treatment. Some would be shut down or sold to industry — these would be easy to identify, according to a BMFT spokesman. Others will be maintained, after excess has been pared away, as institutes for applied research under the Fraunhofer Gesellschaft or perhaps even as part of the Large Research Establishments (*Grossforschungseinrichtungen*). There will be plenty of painful choices, especially within institutes that have to be reduced in size. "I have to consider the existence of the institute first, before the jobs of individual employees," said Parthier, who is giving up his summer holiday to begin the task. "But I have known these people for many years, and it is not their fault that they are in this position."

East Germans who had hoped for salvation through the Max Planck Gesellschaft (MPG) will be sorely disappointed by the announcement at the MPG annual meeting in Lübeck on 20 June that East German institutes would not be absorbed. Incoming MPG president Hans Zacher said the dialectical approach to science in East Germany had "turned on its head" the successful West German approach (which originated in the nineteenth century under the Reich) allowing freedom of research with generous state and industry support. "Trying to unify the two systems could destroy them both", he warned. "There is a lot of useful research in East Germany. . . Our problem is how to integrate it into a system based on freedom without changing ourselves." Simon, who is also director of a Max Planck Institute, considers such fears unreasonable. "We will not be 'infected' by the East German mentality, as some are supposing", he added. "Instead", he said, "we have to develop a 'we' mentality" together with the East Germans.

Steven Dickman

SCIENTIFIC MISCONDUCT

Investigators investigated

Washington

A year after it was first created, the National Institutes of Health's Office of Scientific Integrity (OSI) is still getting an on-the-job lesson in the difficult art of investigating scientific misconduct. Faced with a growing case load (nearly 80 at the last count), congressional and media scrutiny and criticism from universities and scientists who have passed through its doors, OSI is under pressure to prove in its second year that it can deal effectively with misconduct without stifling research.

The first step it will take is to publish, in the coming weeks, a set of formal procedures describing how OSI works. Included will be rules that will give those found guilty of misconduct a chance to negotiate their own sanctions and those found innocent a greater opportunity to clear their names. Congress is also considering taking matters into its own hands. A draft bill now being circulated by the subcommittee on investigations and oversight of the House of Representatives Science Space and Technology Committee would set new guidelines to assure fairness in university misconduct investigations and increase the protection of whistle-blowers.

Legal rights?

The lack of any published procedures has fuelled the principal complaint against OSI that it fails to accord basic legal rights to people accused of misconduct. And, because no one knows what action is being taken, OSI appears to take far too long to complete an investigation — the inquiry into the case of the *Cell* paper written by David Baltimore and others has now been running for over two years.

Another celebrated case, that of AIDS researcher Robert Gallo, raised new criticisms when OSI decided to appoint a National Academy of Sciences panel to oversee its investigation. If an oversight panel was needed in this case, why not in others? "It would appear that the entire *ad hoc* 'process' has been devised with at least one purpose in mind — protecting NIH from congressional criticism", wrote former Health and Human Service (HHS) deputy counsel Robert Charrow in last month's *Journal of NIH Research*.

The most severe criticism of the NIH investigatory process comes from those who have suffered at its hands. "Potentially career-destroying investigations should not be carried out the way mine was", says David Bridges, a Purdue University vision researcher who was found guilty of plagiarism by an NIH investigation last year (see *Nature* **340**, 173; 1989). In the three years since allegations were first made in his case, Bridges says he has spent uncounted hours and well over $20,000 of his own money on his defence. He still protests his innocence and is the only researcher to have gone through every appeal process up to and including a just-completed four-week debarment hearing.

Bridges must now wait until the end of the year to learn if, as a result of the hearing, the Department of Health and Human Services (HHS) will reverse the earlier NIH decision or concur and ban him from receiving federal grants. Until the debarment hearing earlier this month, Bridges claims that neither he nor his lawyers had been allowed to cross-examine witnesses or take testimony on the record.

Under the current NIH rules, a researcher "can be debarred without even getting the chance to testify", complains Bridges' lawyer, Houston attorney Leslie Ribnik. Debarment hearings are granted at the discretion of HHS. There are no laws that compel NIH to call the accused researcher to give evidence during earlier investigations, Ribnik claims.

University regulation

Although OSI has operated without making its own procedures public, it has laid out a set of rules for how universities receiving HHS money should conduct their misconduct hearings.

Once alerted to the possibility of misconduct, the university is expected to put together a panel to review the charges in no more than 60 days. If the panel finds cause for a formal investigation, the university is to conduct an investigation within 120 days. At the investigation stage, the university must inform NIH and submit a report on the outcome to OSI. If it is dissatisfied it may then carry out its own investigation.

Although institutional guidelines have been in print for over a year, there are still doubts over whether they are fair, in the sense of whether they grant the accused adequate rights of "due process".

One problem is that at no time is an accused researcher guaranteed the right to see the evidence or hear the charges against him or her. "You can spend a lot of money trying to respond to unnamed people and uncharacterized charges. Meanwhile, your funding can be halted and your grant application can be denied", says Barbara Mishkin, an attorney with the Washington law firm of Hogan and Hartson.

But Suzanne Hadley, OSI's acting director for most of its first year, says that granting full access to evidence and written transcripts has become OSI policy, even if they are nowhere published. Another unwritten OSI policy is to spell out the charges, although OSI sometimes draws the line at revealing the informant. "We try to depersonalize things — to treat it as a federal office making the accusations. Too often the whistle blowers feel that they're carrying the whole fight on their own shoulders", she says.

The draft congressional bill provides for even greater whistle-blower protection but its authors are wary of going too far. Greg Simon, staff director of the oversight and investigations subcommittee, is concerned that overprotection of informants could create "a new tenure track". If whistle-blowers are made sacred, universities may find themselves unable to dismiss them for legitimate reasons years later, he says. Meanwhile, both OSI and NIH as a whole are considering sanctions against those who make false accusations.

Due process

Simon's bill proposes more emphasis on due process, at least at the university level. For researchers under university investigation, the bill lays out a series of rights, including the right to an attorney, to call and cross-examine witnesses, to present evidence and to file a statement. In return, for universities that accept the guidelines, the bill offers protection against lawsuits by accused researchers.

Full due process within NIH investigations is a stickier issue. Hadley argues that it is inappropriate for OSI. "What we do is not a trial", she says. But others point out that because OSI reports directly to the Office of Scientific Integrity Review, the overseeing body within HHS that recommends sanctions, the combination has the effective force of a judge and jury. "A judicial procedure has due process, an investigation doesn't. "Which is OSI?" asks Charrow.

Inside NIH, criticism of the investigation process has been fanned by messy cases that last years and draw congressional charges of bias or whitewash. "I do have the feeling that these cases should be investigated more diligently and promptly. When misconduct investigations drag on, the public thinks there are more and more of them", says Edward Rall, director of intramural research.

Rall believes that much of the problem lies in the initial investigation by the university. "I'm not sure that all the universities understand that they can't cover up. When they close ranks, they only postpone the moment of truth."

Although NIH plans at present to retain the policy of letting the university do the first inquiry, it is fine-tuning other OSI procedures. Under consideration are 60-or 120-day deadlines — similar to the guidelines for university investigation — on the various stages of the OSI process. But it may be too soon to look for clockwork precision. Says Hadley, "the length of the investigations is one concern — but a lack of balance and objectivity is another."

G. Christopher Anderson

History of Australian prehistory

SIR—A recent News item by Tania Ewing (*Nature* **345**, 9; 1990) contains a number of inaccuracies and misconceptions about the department of prehistory in this school, apparently based on allegations made by Dr Johan Kamminga. One is that there has been a 'Cambridge cabal' ensuring that Cambridge graduates dominate the staff appointments and that British graduates get the more senior posts. The facts are that since its establishment in 1961 there have been only seven tenured appointments in the department of prehistory. When the first two tenured appointments were made in the early 1960s, there were no PhD graduates in prehistory from any Australian university. Any appointees would have required overseas qualifications. At the time of their appointments, tenured staff held a total of 16 degrees from courses of university studies. Of the 16 degrees, only four were from Cambridge. Five were from Sydney. In 1989, the nine academic staff (tenured and non-tenured) held a total of 21 degrees, three of which were from Cambridge. Five were from Sydney.

Neither is Cambridge dominant as a source of students. Of the 32 students who have completed PhDs in the department, only three took their first degree at Cambridge. Four were from Sydney from a total of 12 from Australian universities.

The assertion that Cambridge dominates is not supported by the facts. One could claim a Sydney network with more justification, but such a claim would be equally untrue. The school, including the department of prehistory, seeks to make the best possible appointment from applicants on the basis of merit, not place of origin.

A major misconception in the article leads to the implication that, following the 1978 review of the school, the department of prehistory is at fault in not shifting its interest towards South-East and East Asia. This was not a general requirement throughout the school. Neither was recruitment of students from these areas a requirement, and indeed has never been a deliberate policy. The school takes students, and awards scholarships, on a competitive basis from all over the world, without any regional preferences. The department of prehistory recruits students interested in working in its field areas, Australia and Melanesia, regardless of the place of origin of the students.

The assertions that electoral committees have been "stacked", that Australian graduates get junior posts while "British graduates get the more senior positions" or that the department of prehistory in this school is a "Cambridge academic colony" are quite simply untrue.

R. GERARD WARD

Research School of Pacific Studies,
Australian National University,
GPO Box 4, Canberra, ACT 2601, Australia

SIR—Before your readers conclude that the prehistory department at the Australian National University is a 'Cambridge circus' and especially before there is a rush of Cambridge graduates looking for certain tenured employment in Canberra, I hope you will allow an all-Australian member of the department to correct Tania Ewing's report.

No member of the department has seen Dr Johan Kamminga's allegations so it is difficult to judge whether they are all as inaccurate as the ones he makes public.

In its 21-year history, this research department has had only seven tenured academic staff. Four had Cambridge undergraduate training but two of these obtained Australian PhDs as the basis of their appointment here.

Jack Golson and John Mulvaney were recruited from Auckland and Melbourne respectively to found Australia's first prehistory department in 1969, so by definition their training was non-Australian. It is not surprisingly that they both received it at Cambridge, then, as now, one of the most distinguished centres of teaching and research in prehistory.

Golson and Mulvaney's ethical and research standards have been major reasons behind the dramatic expansion of prehistory in this region and why the indigenous people of the area have become so interested in it.

It is therefore outrageous for Kamminga to claim that these scholars, two of the world's most respected prehistorians, 'fiddled appointments' from the time they arrived in Canberra.

The next tenured post in the department was not filled until 1972, but your readers can make their own assessments as to whether the subsequent tenured staff — Rhys Jones, Jim Allen, Doug Yen, Matthew Spriggs and myself — had to be 'fiddled' or were appointed because of our publications and research skills.

It is interesting that Kamminga's degrees, like my own, are from the department of anthropology in the University of Sydney. Of the seven tenured prehistorians at our *alma mater* over the past 29 years, all but two have had at least one Cambridge degree. I am certain though that, like us, they simply make the best appointments on the increasingly rare occasions when there is a vacancy to fill.

Ungodly thoughts

SIR—Am I alone in being surprised at the number of debates, in the pages of *Nature*, on religion and the existence of god? Most recently this was apparent in the review of Sir John Eccles' new book (*Evolution of the Brain: Creation of the Self*: *Nature* **344**, 117; 1990), and the subsequent reply from god (as revealed to Ralph Estling, **344**, 582; 1990). Although, as in this example, references to god in *Nature* are usually frivolous, this is not always the case (see, for example, **337**, 498; 1989), and the ways in which religion affects the world at large are certainly not a laughing matter (as I am sure Mr Salman Rushdie would testify). Yet *Nature* seems to be according respectability to religious beliefs.

As scientists, should we not be protesting at the way religions permeate society and intrude into our lives, whether or not we want them to? Or, if not protesting, at least making our views known? In a straw poll that I conducted in this medical school, only eight of the 63 people I questioned had any form of religious belief. I suspect that this low incidence of religious beliefs is true of scientists in general, but it would be nice to know for sure.

I would like to suggest that *Nature* should conduct an opinion poll on the religious beliefs of its readers. If my small sample was typical, such a poll could indicate the strength of the atheist lobby (the silent majority?) in science. What would this achieve? Probably nothing, but who knows? Governments might resolve to bring to a halt the religious indoctrination of children. If children were informed on how many different religions there are, and on the fact that if any one of them happened to be right, all the others would be wrong, they might without much difficulty deduce the liklihood that all religions are wrong. Religious programmes on radio and television could come with a government health warning. People might even begin to realize that what happens to our world depends on us.

Nature would be performing a valuable public service by such a survey. The international readership of the journal would enable us to ascertain whether the prevailing religion of different countries influenced the extent of rejection of religious belief by scientists. Whatever the outcome, it would be good to know how many of us think that man created god (in his own image, of course).

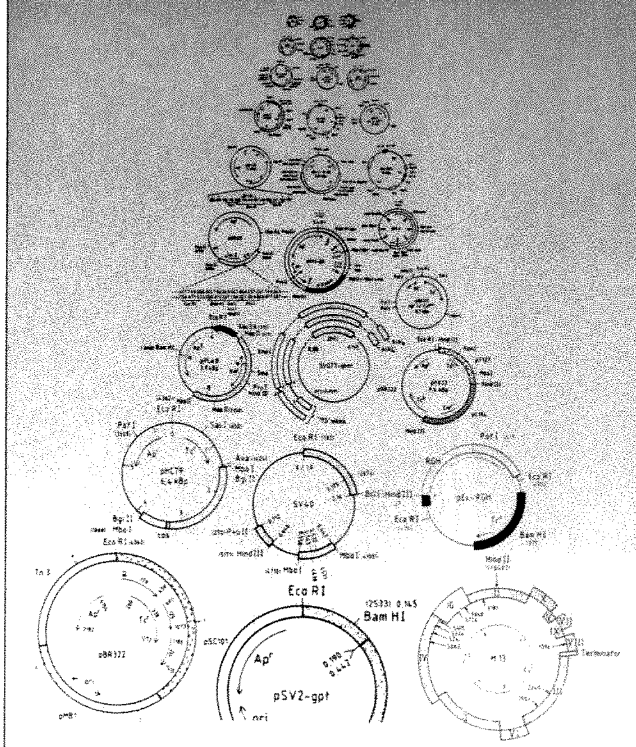
Plasmid preparation with highest efficiency

NUCLEOBOND® AX Plasmid Kits



- High purity of the plasmid
  Equivalent to DNA isolated by CsCl gradients
- High recovery
  Above 90% from 50 ng to 500 µg
- Rapid
  Up to 20 preps in about 1 hour
- Easy to handle (only four steps)
  1. Alkaline cell lysis
  2. Adsorption of the lysate
  3. Cartridge washing
  4. Elution of pure plasmid DNA
- Ready to use
  Kits contain everything you need for the purification
- Safe
  Only non-toxic reagents are used

Please ask for further information!

Better things for better living DUPONT

Reader Service No. 690

Carbon dioxide will be harder

Last week's successful review conference of the Montreal Protocol on ozone would have served an even better purpose by spending more time on verification and compliance.

LONDON had hardly said goodbye to last week's gathering of the parties to the Montreal Protocol on ozone than it was filled with the delegations of the members of the North Atlantic Treaty Organizations, who will be discussing (among other things) the prospects for further arms control measures in Europe. There seems little doubt that the people at the earlier gathering are a more trusting lot than those at the second. What does either group have to learn from the other?

For decades, it has been taken for granted that there can be no arms control without verification. The assumption has always been that the stakes are too high to take the other fellow's word on trust. This is one of the reasons (there were several others) why, in 1979, the then US President Jimmy Carter did not send the SALT II treaty (on strategic arms) to the US Senate for ratification: as negotiated, it allowed only for 'national means' of verification, which was a euphemism for the use of surveillance satellites. By contrast, the treaty on nuclear missiles of intermediate range, signed at the end of 1988, and the START treaty now being negotiated, include provisions for the direct inspection of disarmed missiles, sometimes on unprovoked demand.

The Montreal Protocol does not yet have teeth like that. Even in its newly tightened form (see page 6), the convention is not especially specific about the the baseline data, for 1986 and 1989, against which future reductions of chlorofluorocarbons (CFCs), and variants on that theme, are to be assessed. The secretariat requires of the governments that are members of the convention that they supply details of production and consumption of the various materials interacting with ozone in the stratosphere. And where will those data come from? The only possible sources are the companies that manufacture them, and which must be supposed to have a vested interest in inflating their first estimates so as, later, to be less hurt by the proportionate reductions to which they have agreed.

At least on past form, the arms controllers would not so easily have taken what their fellow signatories had to say about their own dispositions as synonymous with the truth. In the absence of 'national means of verification', there would have been calls for lists of the manufacturing plants at which offending operations were being carried on, as well as for opportunities for inspecting them. For what it is worth, the signatories of the Montreal Protocol might reasonably have bound themselves to provide a list of the plants manufacturing CFCs and the other substances now controlled, if only so as to be better able to tell what to make of newly constructed plants if they should make their appearance in the years ahead.

It is also surprising that the Montreal Protocol is as innocent as it seems of formal arrangements for the systematic monitoring of the now-controlled materials. The ostensible objective of the enterprise is to regulate the concentration of these chemicals in the stratosphere, for which purpose the tropospheric concentration is a legitimate proxy. But the measurements by which the supposed increasing concentration of, for example, CFCs has been verified have mostly been carried out with air samples collected from oceanic islands.

That makes sense if the objective is to detect trends unencumbered by locally generated noise, the nearness of a chemical plant for example. Now that the convention has been made more stringent and its scope extended, its members cannot be expected to continue to rely on whatever measurements of this kind independent investigators choose to carry out, but it is plainly of more than passing interest to them to know something about sources of regional or even local noise that may betoken the presence of unsuspected chemical factories.

These issues have been given close attention over the years in negotiations to control the manufacture of chemical weapons, mostly at Geneva (in the building in which the United Nations Environmental Programme has its European office). Not so long ago, the Finnish authorities explored the use of civil aircraft equipped with air samplers and gas chromatography as a means of telling what kinds of chemical plants lie beneath civil airline routes. Fitting the exhaust stacks of all chemical factories with sealed automatic samplers would be more effective, but would encounter the objection raised, during the test-ban negotiations in 1978, that remotely operated seismometers would provide much more extensive data than were required for the working of the treaty. Even in the cause of the Montreal Protocol, not every chemical manufacturer would welcome others knowing what flows up his chimney stacks.

Yet another lacuna in the new arrangements is financial, and concerns the procedure for recompensing developing countries for their willingness not to make CFCs, but only the substitutes for them, and to lag no more than ten years behind the rest in full compliance. It is, of course, remarkable that so many rich countries have agreed to contribute to what is called the multilateral fund to compensate developing countries for their self-denial. But it will be a headache for the lawyers and the accountants. The preamble to last week's conference document records the need to avoid "double-counting". But only trusting folk like the ozone people would have let things get this far without calling in teams of lawyers to draft their resolutions.

That is as it should be. It would have been absurd to have invested the ozone negotiation with all the niceties of the arguments there have been in the avoidance of nuclear war. That does not imply that the ozone problem is not serious, but that it is a less serious problem than the threat of nuclear war. And, as the signatories of the Montreal Protocol openly confess, the last thing on their agenda was to frighten off non-signatories by too elaborate a system of control. Fair play, the strategy has worked. It is a victory that China and India may now join.

So why rehearse the gaps in the convention that will send the world's arms controllers into shivers? Because the convention is more than a means of reducing the incidence of skin cancer, it is a model for the convention there will soon have to be on the control of the emission of greenhouse gases (among which the CFCs are incidentally important in their own right). And there the stakes will be much higher, perhaps even comparable with the threat of nuclear war. People will be less willing than over ozone to trust others to tell the truth, from the fear that they may be lying.

That is why a few arms controllers might usefully get together, in the wake of last week's successful conference, to advise the ozone people on the ways in which their protocol might have been made not just a declaration of good intentions, but watertight as well. The exercise would of course be unnecessary and thus academic, but a version of it will be needed when work begins on carbon dioxide.

John Maddox

PULSAR ASTROPHYSICS

Good things come in threes

Charles Bailyn

THE high density of globular star clusters is believed to be conducive to pulsar formation. But although recent years have indeed seen a stream of pulsar discoveries in these systems (19 are now known, whereas none were three years ago), the observations continue to bring forward as many questions as they answer. The discovery by Anderson *et al.* of the second and third pulsars in the very dense cluster M15 (Fig. 1), reported on page 42 of this issue[1], is especially significant, both for the innovative method used to detect them and for the interesting properties of the two pulsars and of the cluster itself.

Pulsars are rapidly magnetized neutron stars. They emit beams of electromagnetic radiation from the magnetic poles, which are observed on Earth as pulses of radio emission as the beam sweeps across once with each rotation. The pulsars in globular clusters belong to a subclass often referred to as 'millisecond' pulsars, although in fact their observed pulse periods range from a few milliseconds to a few tenths of a second. The search for pulsars usually involves taking a Fourier transform of a long time series of radio measurements to look for a periodic signal amidst the background. This search must be made for different values of the dispersion measure — the amount of ionized gas between the observer and the pulsar — because the speed of light for a given frequency depends on the column density of this intervening plasma. Without a correction for this effect, the pulse arrival time will vary with frequency, resulting in an undetectable 'dispersed' pulse. But there is little, if any, gas within globular clusters, so the dispersion measure is the same for all pulsars in a given cluster. Anderson *et al.* have taken advantage of the previous discovery[2] of a pulsar in M15, from which was determined the dispersion measure towards the cluster, to greatly increase the sensitivity of their search, which has resulted in the discovery of two fainter pulsars.

The improved sensitivity comes about in two ways. First, long series of data can be analysed with much less computing effort, as only one value of the dispersion measure need be considered. Second, a strong 'selection effect' that normally mitigates against finding pulsars in binary star systems with short orbital periods can be at least partially removed. The selection effect arises because the observed pulse period varies, and the signal in the Fourier transform is consequently reduced, as the pulsar in a binary system is accelerated relative to the Earth by its orbital motion. Anderson *et al.* have used the improved computational efficiency made possible by knowing the dispersion measure to search for the variable pulse periods that would be created by a range of constant accelerations. This procedure resulted in the discovery of the third pulsar, PSR2127+11C, which could not otherwise have been detected.

Indeed, it is the short orbital period (about eight hours) of PSR2127+11C that makes its discovery particularly exciting. Its orbital parameters are remarkably similar to those of PSR1913+16, which has been used for a sensitive test of general relativity[3]. The exquisite accuracy possible for timing measurements on short-period pulsars means that it is feasible to look for various relativistic effects, including the decrease in period of the orbit through emission of gravitational radiation. These effects should be observable in PSR2127+11C within a few years.

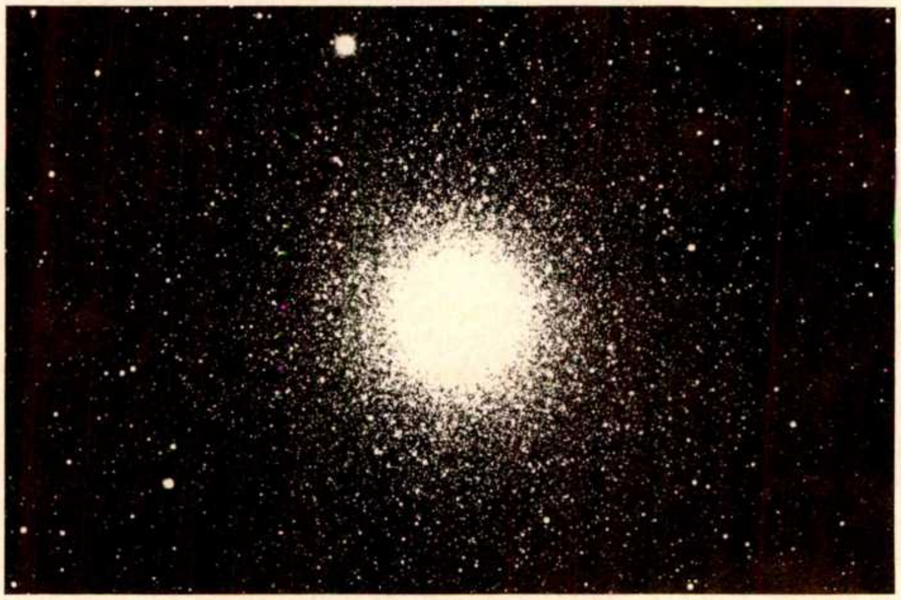

FIG. 1 An optical image of M15 taken at the Kitt Peak National Observatory. The two pulsars (A and B) for which accurate positions are known are located at the centre of the bright region.

M15 is itself an interesting cluster, being the best-studied member of a class of clusters that have strong cusps in their central density (Fig. 2). These cusps are a signature of an advanced stage of cluster evolution. The high central density should give rise to a large number of stellar collisions and near misses, which are thought to result in the formation of accreting neutron stars in binary systems — the precursors, according to the standard scenario, of millisecond pulsars. Thus M15 should be a fertile breeding ground for pulsars, as the new observations seem to confirm.

The three pulsars in M15 provide probes of the cluster's dynamics. The first of them[2] shows an unprecedented increase in spin rate with time — all other pulsars are slowing down. This is not thought to be an intrinsic property of the pulsar, but instead a result of the strong gravitational acceleration caused by other stars in the cluster. Thus measurements of pulsar timing can probe the cluster's gravitational potential. The locations of the pulsars within the cluster reveal the operation of dynamical processes: pulsars A and B, for which positional information is available, are within a few arcseconds of the cluster centre, indicating that these relatively massive systems have fallen there as equipartition of energy has become established through interactions with other cluster stars. Finally, the fact that two of the three pulsars in M15 are not binaries is in itself revealing in terms of their dynamical interactions with other stars. Although millisecond pulsars are thought to be born in binary systems, a recent study[4] of the dynamics of M15 shows that encounters with a third star are likely to lead to the 'ionization' of a binary pulsar (that is, the loss of its companion).

But the stories told by pulsars about their parent clusters are not limited to the clusters' dynamics — they also reveal problems with generally accepted theories of stellar evolution. The basic difficulty is that there are so many globular-cluster pulsars. As distances to globular clusters are large, only the very brightest pulsars will be observable; thus the pulsars observed probably represent only a small fraction of the total population. Recent extrapolations[5,6] suggest that there may be as many as ten thousand pulsars in galactic globular clusters. Neutron stars are created in supernova explosions of stars with ten or more times the mass of the Sun, so this large number of pulsars requires a large primordial cluster population of massive stars. In M15 and several other clusters, however, studies[7] of the remaining unevolved stars (all less massive than the Sun) show that the number of stars drops off very sharply with increasing mass. Thus the function that describes the variation with mass of the frequency of occurrence of stars must be more complicated than the simple power law that is usually assumed.

This requirement for a large number of neutron stars also poses problems for the stability of the clusters as a whole, because the mass loss during the evolution of a large population of massive stars has been shown to result in complete disruption of the cluster[5]. Furthermore, neutron stars in binaries are spun up to 'millisecond' periods by accreting material with high angular momentum from their companions. Such accreting neutron stars are indeed observed in globular clusters as strong X-ray sources, but estimates of the birthrates of these systems are orders of magnitude too small to account for the inferred number of pulsars[5,6].

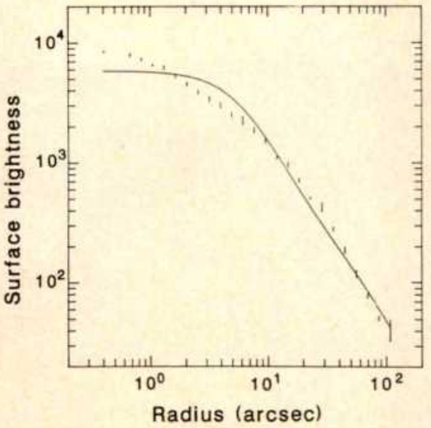

FIG. 2 Radial density profile of M15 (from ref. 9). At small radii, the data (short horizontal lines) considerably exceed the predictions of the King model[10] (solid line), which fits most globular clusters.

Now that we know where and how to look for millisecond pulsars, we can expect the stream of discoveries to become a torrent. There should soon be many more opportunities to exploit the unique tests of gravitational theory provided by pulsars, as well as to learn more about the evolution of stars and star clusters. ☐

QUANTUM MECHANICS

No need for nonlinearity?

Richard Thompson

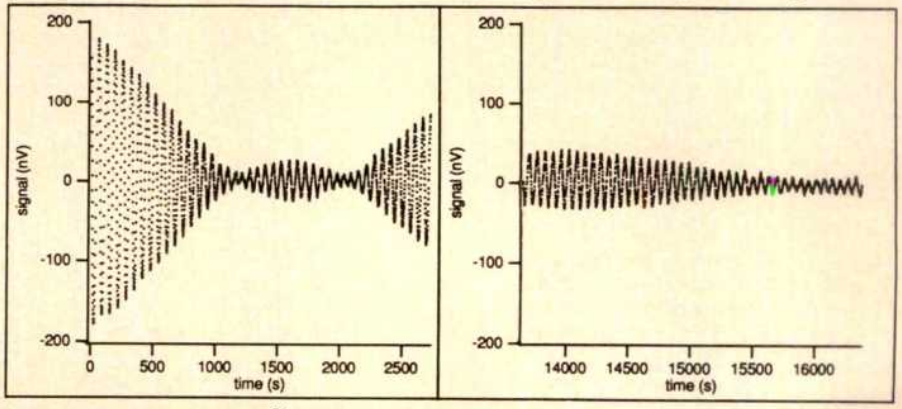
CLASSICAL oscillatory motion, such as that of a simple pendulum, can become nonlinear at large amplitudes, whereby a dependence on amplitude starts to creep into the resonant frequency. Last year Weinberg[1] proposed that similar nonlinear corrections might be necessary to the wave equations of quantum mechanics: this idea was tested subsequently to high accuracy in a study of trapped beryllium ions by Bollinger *et al.*[2]. Chupp and Hoare[3] have now reported a similar test from a different kind of experiment based on spectroscopy of the ^{21}Ne nucleus. They find that any nonlinear corrections to the usual linear quantum-mechanical formulation must be tiny: smaller than 1.6×10^{-26} of the binding energy per nucleon in ^{21}Ne atoms.

Although quantum mechanics has no difficulty in providing a description of nonlinear effects, Weinberg[1-4] revived the question of whether the usual linear form of quantum mechanics is complete. He proposed a class of possible corrections to the usual hamiltonian function, which is linear in the product of ψ and ψ^* (the wavefunction and its complex conjugate). These corrections are nonlinear in the product of ψ and ψ^* and can be cast in such a form that the hamiltonian still describes separated systems correctly. The consequences of such corrections can be calculated and tested in the laboratory; but there is as yet no experimental evidence that they are necessary. One particular consequence would be that the principle of linear superposition of wavefunctions would no longer hold. It is this aspect that the experiments set out to test.

I have discussed the Be$^+$ experiment previously[5]. It involved the investigations of an essentially two-level system within the hyperfine structure of the ground state of ^{9}Be$^+$. A cloud of ions was held in an ion trap and cooled by collisions with laser-cooled Mg$^+$ ions held in the same trap. The ions were prepared in a superposition of the two levels by a microwave pulse and the precession frequency of the nuclear spin in an external magnetic field was measured to very high precision. Nonlinear corrections to quantum mechanics would show up as a dependence of the precession frequency on the degree of excitation of the ions — the frequency should change as the amplitude of the excited state in the superposition state is changed. No nonlinearities were detected at the level of 4 parts in 10^{27} of the binding energy per nucleon of the ^{9}Be nucleus.

Chupp and Hoare[3] have chosen to study the ground state of the ^{21}Ne atom, which has a nuclear spin of 3/2. The atoms are placed in a weak (about 3 gauss), uniform magnetic field B, which splits the ground state into four levels (labelled by the quantum number M_I) such that the three transition frequencies between pairs of adjacent levels are all about 995 Hz. These three frequencies are monitored as a function of the degree of alignment ('tensor polarization') of the system: a measure of the degree to which the system is in the outer ($M_I = \pm 3/2$) states rather than the inner ($M_I = \pm 1/2$) states. Nonlinearities of the simplest form to satisfy the conditions mentioned earlier will cause these frequencies to vary in a particular manner.

Assuming that the nonlinearity is characterized by a small parameter ε (with dimensions of energy), each of the four M_I levels is shifted by an amount proportional to ε and dependent on the exact state that the system is in. If ω_1 is the transition frequency between the $M_I = 3/2$ and 1/2 levels, and ω_3 is the transition frequency between the $M_I = -3/2$ and $-1/2$ levels, it turns out that the difference frequency $\omega_1 - \omega_3$ is equal to $(2+T_2)\varepsilon/\hbar$, where T_2 is the alignment of



Coherent free precession of ^{21}Ne over 4.5 h. The signals show beats due to the tiny differences between the three transition frequencies for the four-level system. The traces can be fitted to theoretical curves to extract the three frequencies and their damping coefficients; the degree of alignment can be extracted from the relative amplitudes of the frequencies.

the system. Thus if the system is prepared in superposition states with varying amounts of alignment, this difference frequency should change if nonlinearities are present. The technique, developed from earlier experiments that searched for violations of Local Lorentz Invariance[6], uses a cell containing both ^{21}Ne and ^{3}He. The nuclear spin of ^{3}He precesses in the magnetic field, but shows no nonlinear effects as it has a spin of only 1/2. The precession frequency is about 9,600 Hz, which is divided electronically by 9.649 to give a reference frequency about 1/60 Hz away from the ^{21}Ne precession frequency. The beat signal between the two frequencies can be followed for a period of 2,700 s before the He signal decays. The Ne signal can, however, be measured over a period of 4.5 h if the helium atoms are re-excited periodically. The neon atoms are initially polarized (put into specific spin states) via spin-exchange collisions with Rb atoms excited by laser irradiation. Once the polarization is established, the cell is cooled to freeze out the Rb vapour, and a pulse of resonant oscillating magnetic field tips the neon spins by 20°. Their free precession is then monitored with a pickup coil. A critical feature of the experiment is that any small variations in B do not influence the results, as the helium atoms providing the reference frequency sample the same field as the neon atoms. The important difference frequency is then relatively insensitive to the field fluctuations.

A typical trace of the beat signal is shown in the figure. From these traces, $\omega_1 - \omega_3$ can be found as a function of T_2, giving a limit for ε/h of 12 ± 19 μHz. Comparing this with the binding energy per nucleon of the ^{21}Ne nucleus gives a fractional nonlinearity of less than 1.6×10^{-26}, similar to the Be ion-trapping experiment.

What does all this signify? The Weinberg model has been designed to incorporate nonlinearities in as general a manner as possible, but it is of course possible that a different model is needed. It is also possible that nonlinearities are present but only at an even smaller level; in that case their detection may not be feasible, as these experiments are already extremely sensitive because of the very long interaction times involved. But it seems most likely that a linear quantum-mechanical description of matter is sufficient and that nonlinear corrections are not necessary. □

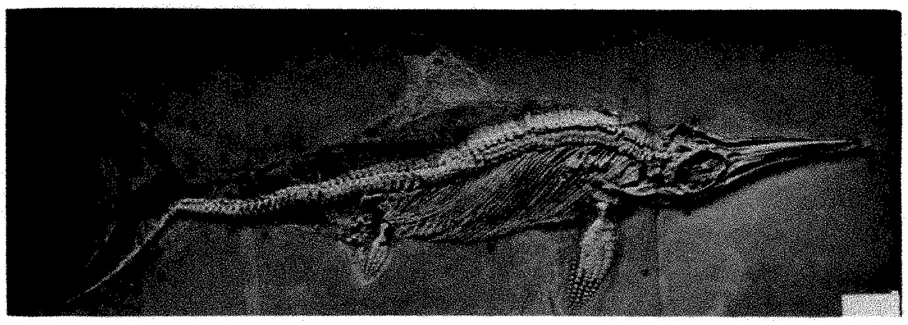
PALAEONTOLOGY

Two dietary developments

Michael A. Taylor

Kipling[1] traced the origin of the baleen whales to one which unwisely ate a "shipwrecked Mariner of infinite-resource-and-sagacity", who cut up his raft into a small square grating and rammed it down the animal's throat. Today's hypotheses for the origin of major vertebrate groups are tested rather more rigorously by fossil evidence and internal logic. Two recent and apparently disparate examples show how illuminating that approach can be where a group's key adaptation has changed its function, or when the original shape of members of a group has been transformed. In one report[2], Bodmer argues that the stomach of ruminant mammals such as cattle and sheep, now used to digest grass and fibrous plant material, evolved to deal with tough fruits. In the other[3], Massare and Callaway show that ichthyosaurs, the marine reptiles famous for resembling sharks and dolphins even down to the deep double-lobed tailfin, did not even have tail fins to start with, but that such tails became advantageous with a change in feeding patterns.



University Museum, Oxford

Ichthyosaurs — these creatures may have evolved from shallow-water predators.

The stomach of ruminants contains a compartment, the rumen, in which plant food is fermented by symbiotic microorganisms in between regurgitation and further chewing (as the cud). Otherwise indigestible fibre can thus be broken down into assimilable nutrients: this has enabled ruminants to become today's dominant large herbivores feeding on fibrous grass or browse. But fermentation tends to waste free nutrients already present in high-quality food such as fruits, so that the ruminant stomach would seem to be a handicap to frugivores. Fossil evidence indicating that the first ruminants fed on fruits in Eocene tropical forests (50–42 million years ago) seems, therefore, strange.

Today's closest equivalents to the original ruminants are the red and grey brocket deer (*Mazama americana* and *M. gouazoubira* respectively), small Amazonian forest frugivores. They feed especially on palm fruit, the seeds of which are highly nutritious but heavily protected against attack. Most mammals that eat them break or gnaw through the shell, but the deer simply swallow the seeds whole for digestion and softening by rumen microorganisms, before rechewing.

In Bodmer's view[2], the ancestral ruminant stomach originally evolved to cope with such tough fruits, and then became used increasingly to digest other fibrous plant parts such as leaves. Interestingly, brocket deer show this dual use, eating more nonfruit material when stranded on temporary islands during floods. As the Eocene forests were very similar to Amazonia today, this is a tempting model for the transition.

The diversification of ruminants during the Tertiary coincides with the decline of nonruminant ungulates, not because they were inherently superior, but probably because climatic and vegetational changes, such as the development of grasslands, favoured their ability to process small amounts of food efficiently (the nonruminants' form of intestinal fermentation requires more food and a greater throughput of it)[4]. But nonruminants can be superior under different conditions. So the new hypothesis[2] has the merit of invoking a specific qualitative advantage of rumen fermentation: the fruits can be fermented and then returned to the mouth for further chewing in a manner which would be impossible for otherwise efficient hindgut fermenters, unless they consume their own faeces: hardly practical for a large, mobile mammal.

In the second example, Massare and Callaway[3] use new data on ichthyosaurs from the Triassic period (248–213 million years ago) to conclude that ichthyosaurs are most probably members of the Diapsida, a large group of reptiles characterized by the presence (in most) of two pairs of openings in the sides of the skull behind the eyes, for jaw muscle attachments. If so, ichthyosaurs must have lost the lower pair of openings. Their origins lie among the primitive lepidosauromorphs (the diapsid group including tuataras, lizards and snakes), and the apparent discrepancies — such as the lack of a breastbone, present in primitive lepidosauromorphs

— seem to be related to their transformation into aquatic reptiles.

A near-monopoly of marine reptiles in the Mesozoic (250–65 million years ago) was thus enjoyed by the Diapsida, which apparently include the placodonts[5] and nothosaurs (and by implication plesiosaurs)[6,7], as well as the sea-crocodiles and mosasaurs (giant marine lizards). Was this just luck, or was the diapsid skull particularly effective for aquatic feeding?

Paradoxically, answers to this question are best answered by examination of the postcranial skeleton. Primitive diapsids retained the basic reptilian terrestrial locomotor pattern of side-by-side undulation of the body and tail, increasing the thrust of the limbs, while the powerful tail muscles helped to pull the hindlimb backwards. This basic undulation is also used for swimming, with the limbs trailing. Triassic ichthyosaurs had longer and more flexible necks and bodies than the more dolphin-shaped forms that evolved later. The Triassic forms must have swum by the same undulation of the body and tail that propelled their terrestrial ancestors. A relatively broad, long tail fin, which was an enlargement of the natural keels of the tail, helped generate thrust over most of the animals' length. In contrast, later forms relied mainly on tail movement with force produced by rapid oscillation of an enlarged, bilobate or even crescent-shaped tail fin. This was ideal for maximizing thrust and minimizing drag in steady swimming — perfect for cruising or fast pursuit of prey in open water.

But Triassic ichthyosaurs were not inferior intermediates between terrestrial reptiles and Jurassic ichthyosaurs. The long body and tail permitted large amplitude oscillations and rapid acceleration — useful for ambush predation — and the broad tail gave a burst of power for rapid starts[3]. Massare and Callaway thus envisage ichthyosaurs as evolving from shallow-water, elongate, crocodile-like predators — in other words, little more than a standard reptile — through a more aquatic but still elongate coastal ambush predator, to the dolphin-like open-water, deep-bodied predators of the open sea. The high degree of adaptation of the intermediates is a particularly pleasing refinement to what was thought to be a well-understood evolutionary development.

The new reports show what insights can be garnered from a marriage of palaeontology and the comparative anatomy of function in living animals. They are, of course, just two of many examples, which together constitute a scientific success story of which Kipling would surely have approved. ☐

EVOLUTION

Mountaineering with microbes

Daniel E. Dykhuizen

MICROORGANISMS are well suited to experimental studies of evolution. They have such short generation times that observations of evolutionary change over thousands of generations are possible not only within the lifetime of a scientist, but even within the duration of a grant. Such experiments often give rise to surprising and unexpected results, as demonstrated by the report of Bennett, Dao and Lenski on page 79 of this issue[1].

The authors adapted a population of *Escherichia coli* to growth at 37 °C in a minimal medium by serially transferring the population for 2,000 generations. During this time, the population became well adapted to its environment. From this population a single cell was isolated. The clone derived from the cell was split into six experimental and six control populations, the control populations then being grown in the same environment as before — minimal medium at 37 °C. The experimental populations were grown in the same way and in the same medium, but at 42 °C. After 200 generations, the experimental populations had evolved. In the control populations, there was no measurable change, even after 400 generations. So far there is nothing unexpected in this: rapid evolution in a new environment; none in an environment to which the cells are already well adapted. What might not have been expected is that such similar environments — only 5 °C difference in temperature — lead to different evolutionary responses. The surprise is that the populations evolved at 42 °C were also fitter at 37 °C than the control strains.

Evolutionary biologists have a mental picture of the adaptive process. Fitness is represented by smooth-surfaced mountains, and an adaptive mutation allows a species to climb a little higher on the mountain. If the environment does not change, the species will approach the peak, and as it does so we expect the advantageous changes to become rarer and smaller in effect. In the experiment carried out by Bennett *et al.* this occurred during the first 2,000 generations at 37 °C such that there is no evidence for any further adaptation after 1,500 generations. So it seems safe to assume that the population is sitting near the top of the adaptive peak.

If the environment is changed, the topography will be remoulded. New peaks will arise from the slopes of old mountains and in place of old peaks there will be valleys. In this case, we could imagine a new, higher peak arising out of the side of the old peak. The population now evolves towards this peak. When this population is returned to the former environment, it would be expected to be less fit, rather than more fit.

The authors offer two hypotheses to explain their results. First, that the mutations selected at 42 °C are not present at 37 °C in sufficient frequency to be selected. This is possible. But then the adaptive path is dependent upon the available mutations even in large populations where most single mutations would be expected within a few tens of generations. If this is generally the case, the metaphor of the adaptive landscape must be restricted to genetic variation currently in the population. Second, that because of the smaller selection coefficient, the mutations did not rise to a substantial frequency at 37 °C. Again this is possible, but the average fitness increase at 37 °C was 4 per cent, half that at 42 °C. Thus, if these mutations dominated after 200 generations in the 42 °C populations, they should have appeared in the 37 °C populations after 400 generations. Where were they?

I offer two more hypotheses. One is that various epistatic mechanisms are involved. For example, assume that two mutations are required for the increase in fitness at 37 °C. Neither of these mutations alone is advantageous at this temperature, but at 42 °C at least one is advantageous by itself and in combination more advantageous. This proposal also has flaws. It would take between 100 and 200 generations for the first mutation to reach frequencies where the second mutation would happen in the same cell. Then there should be a fitness increase in the period from generation 200 to 400, which was not seen. My other hypothesis is that the selection is frequency dependent. When the mutations are rare, they have very little advantage at 37 °C, but considerable advantage at 42 °C. Further explanations can be added to explain the authors' result, but when one starts piling up hypotheses in this way it is hard to stop. Here we have a warning signal that reality does not agree with our picture and investigation of mechanism becomes a necessity.

This is not the only case of unexpected results in experimental studies of evolution. Paquin and Adams[2] found that a population could evolve such that it became less fit than the starting strain.

Saccharomyces cerevisiae were cultured in a chemostat, a device in which microorganisms can be continuously grown in a nearly constant environment[3]. Every time an adaptive mutation swept through the population, strains carrying this adaptation were isolated and competed against ancestral strains, either the one used to start the population or ones carrying previous mutations. Each strain was fitter than the previous one — the strain carrying the first adaptive mutation was fitter than the starting strain, and the strain carrying the second adaptive mutation (and probably also the first) was fitter than the one carrying only the first. But the strain carrying the third adaptive mutation was selected against when set in competition against the starting strain. So selection is not transitive as the mountain model of fitness assumes it to be. To continue the mountain analogy, this result shows that, as the population climbs a mountain, it can change the topography radically even though the physical environment remains constant.

Even in the simplest system — *E. coli* growing in glucose-limited chemostats — unexpected results occur. Chemostats are designed so that a single nutrient limits growth and the organisms compete for this nutrient. Helling *et al.*[4] used the system to study the adaptive evolution of *E. coli*, expecting to isolate a series of mutations which made the cells increasingly fitter in this constant environment. The approach should have allowed definition of the path to the peak; instead, the original strain 'speciated' into two separate lineages, both being maintained on what seemed to be a single limiting resource. Closer investigation showed that they had evolved such that the resource was divided — one lineage used the glucose, and excreted compounds on which the other lineage could grow. So the image of a rock-hard mountain decomposes into many fitness landscapes, which in turn continually split into new ones as organisms evolve. ☐

PHYSICAL CHEMISTRY

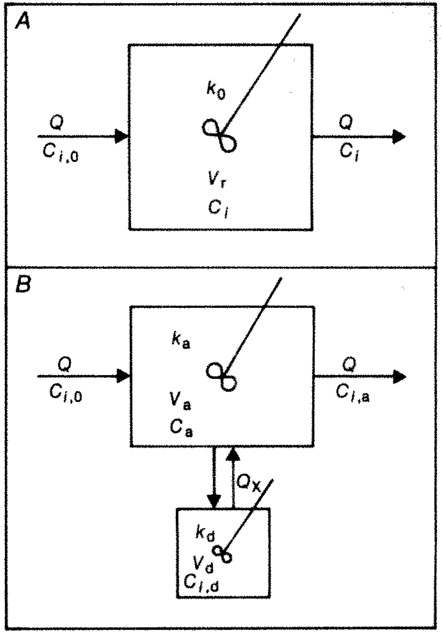
Shaken, stirred — but not mixed

Irving R. Epstein

THE glass stirring rod has largely been replaced by magnetic stirrers, shakers, ultrasonicators and other more sophisticated devices designed to produce homogeneous reaction mixtures in chemical systems. Most chemists carry out their reactions in the belief that any residual nonuniformities remaining in their reaction vessels have negligible effects on the results of their experiments. Evidence has been accumulating, however, that in at least some reactions with the kind of highly nonlinear kinetics that leads to several steady states or sustained oscillation, significant concentration gradients arise despite the experimenters' best efforts to eliminate them. Menzinger and Dutt[1] now report quantitative measurements of macroscopic concentration gradients in the oscillatory chlorite–iodide reaction carried out in a stirred continuous-flow reactor. Concentration differences of up to 800 per cent are found between points near to and far from the stirrer shaft.

Chemical engineers have appreciated for some time that such 'irrelevant' details as the placement of input jets, the shape of the stirrer or the orientation of baffles can influence markedly the output of certain reactor processes[2]. Roux *et al.*[3] showed the dramatic effect of imperfect mixing in nonlinear chemical dynamics when they found that, for the bistable chlorite–iodide reaction, the hysteresis limits (as a function of the rate at which reactants are pumped into the reactor) vary significantly as the stirring rate is varied between 550 and 700 r.p.m., a range in which most chemists would have been confident that the reactor was well mixed.

Several theories have been proposed to describe the interaction of mixing effects and chemical kinetics. Two ideas must be kept in mind. First, the effect of inhomogeneities will be most pronounced when the reaction is nonlinear. If the rate of the reaction is proportional to the concentration of reactant X, [X], and if this concentration is 1M in half of the reactor and 3M in the other half, the net (average) rate will be the same as if the entire system was at a concentration of 2M. If, on the other hand, the rate is proportional to $[X]^2$, the average rate will be proportional not to $2^2 = 4$, but to $\frac{1}{2}(1^2 + 3^2) = 5$: imperfect mixing increases the net rate by 25 per cent. Second, two kinds of mixing must be accounted for[4]: macromixing, in which parcels of fluid from different inlets must be combined to yield equal bulk compositions; and micromixing, in which molecular mixing occurs for inhomogeneities with sizes of the order of the smallest hydrodynamic turbulent length scale.



Models of a stirred-tank reactor. *A*, Ideal, assuming perfect mixing. *B*, Macromixing effects included by postulating an active zone (a) which communicates with the input and output reservoirs, and a dead zone (d) which communicates only with a. The C_is are concentrations of reagent *i*, *k* is the rate constant, *V* is the volume and *Q* is the flow rate.

In one family of models (see figure), which can account for much of the qualitative behaviour, a reactor is pictured as a combination of a well mixed or active (a) zone and a poorly mixed or dead (d) zone. In this model[5], macromixing (but not micromixing) is described by parameters that determine the rate of exchange between the two zones (Q_X) and their relative volumes (V_a/V_d). Better mixing corresponds to a smaller dead zone. Such a model has been employed in recent efforts to explain the origin of chemical chaos in the Belousov–Zhabotinsky (BZ) reaction. In a somewhat controversial interpretation, Györgyi and Field[6] suggested that the observed chaotic behaviour[7], although genuine, arises not from the homogeneous chemical kinetics but from the interaction of these kinetics with imperfect mixing. This view, which was inspired by the inability of chemically reasonable models of the reaction to yield

truly chaotic behaviour, has been tempered by a recent calculation[8] which indicates that a plausible model of the BZ reaction can indeed generate chaos under homogeneous conditions. It now seems likely that chaos in chemical systems may have two sources — complex homogeneous kinetics and/or interactions between kinetics and mixing.

The work of Menzinger and Dutt[1] is unlikely to be the last word on the nature of mixing effects in nonlinear chemical kinetics. The 0.25-mm microelectrode that they use to monitor spatial and temporal variations in electrochemical potential gives only very crude spatial resolution; a recent study of pattern formation in the BZ reaction[9] uses electrodes with micrometre dimensions. By monitoring simultaneously two microelectrodes at different locations in the reactor, Menzinger and Dutt find that when the reactor switches from one steady state to another, both the microelectrodes undergo a change in potential at the same time, even though their absolute potentials are quite different. On the other hand, certain chemical systems in a closed reactor show evidence of a transition between stable states that nucleates locally and then propagates through the system[10]. But although there are clearly questions still to be resolved, chemists are growing increasingly aware of the danger of assuming that they ever conduct their reactions in media of uniform concentration. ☐

IMMUNOLOGY

Tamarin compatibility

Shirley A. Ellis and Andrew J. McMichael

OVER the past few years it has emerged that the major histocompatibility complex (MHC) class I region of human chromosome 6 contains expressed genes in addition to the (so-called classical) A, B and C loci[1]. The classical class I genes encode highly polymorphic transmembrane glycoproteins, whose main role is to present peptides from processed foreign antigen to cytotoxic T lymphocytes. To date, three other distinct loci (E, F and G) have been identified[2] and restriction fragment length polymorphisms suggest that there will be others. The origin and function of these genes have, however, proved elusive. On page 60 of this issue[3], Watkins *et al.* provide insights into the possible function of the products of one of these loci, HLA G, from a surprising source — the cotton-top tamarin.

The authors cloned and sequenced all of the MHC class I genes from a sample of 79 unrelated members of this species, and demonstrate that only 11 molecules are expressed. When these were compared with each other, they showed far less variability in amino-acid sequence than is seen between alleles of the class I loci in either man or mouse; ten out of the 11 molecules are more closely related to human HLA G than to classical A, B and C molecules. We must assume that these 'G-like' molecules are functional in the cotton-top tamarin, because the animals can mount cytotoxic T-cell responses. But when they encounter pathogens not found in their natural environment (Epstein–Barr, Rous sarcoma, measles and parainfluenza viruses, for example), they prove to be particularly vulnerable, a phenomenon which may be related to their lack of class I polymorphism.

We cannot assume however that because the cotton-top tamarin MHC class I appears to function normally, albeit in a limited way, the human HLA G has a similar role. There are several differences to be considered. The two full-length human G (derived) amino-acid sequences that have been reported[4,5] are identical; together with isoelectric focusing studies[6,7] this shows that there is probably no polymorphism (at the amino-acid level) at the G locus. The only cells that have been demonstrated to express the HLA G product are extravillous cytotrophoblast from the placenta and some trophoblast-derived choriocarcinoma cell lines. Thus the HLA G molecule is found only on cells that do not express HLA class I A, B or C. Possibly the most striking feature of HLA G which really sets it apart from classical HLA class I is its truncated cytoplasmic tail — the shortened tail is due to a termination codon at the beginning of exon 6 (the first cytoplasmic domain) that results in a smaller expressed product of relative molecular mass (M_r) 39,000. Although it does appear to be anchored in the cell membrane, this missing portion may have implications for the function of the molecule. The 'HLA G-like' molecules seen on the tamarin cells have a normal cytoplasmic tail, and are the size of classical class I molecules, M_r 43,000.

The human placental trophoblast cells, which are located at the maternal–fetal interface, are thought to play a part in the survival of the semiallogeneic fetus. It was believed that these cells formed an MHC-negative 'barrier' against maternal immune surveillance[8], but recent work has shown that they express high levels of HLA G (refs 5, 7). The function of this molecule is not known — it could be nonimmunological, related to the invasive properties of this tissue, or to the effects of peptide hormones. It may be necessary to have a 'neutral' HLA class I molecule, having a passive but important role, for example, to resist attack by natural killer cells[9]. Selection pressure against polymorphism of an HLA molecule expressed at this extremely sensitive site seems likely, and implies a function fundamentally different from that of the other HLA class I antigens, where a high level of polymorphism plays a crucial part in their immunological activities.

These results raise questions regarding the original nature and role of the ancestral HLA G genes. If the HLA G-like gene products functioned as classical class I molecules in the primate ancestor, they would have needed to 'lose' their polymorphism in adapting to a role in the trophoblast. Alternatively, the ancestral G genes might never have functioned as classical class I molecules; in the tamarin ancestor, accidental deletion of the classical loci may have resulted in an increase in polymorphism at the G locus and a wider tissue distribution. As Watkins *et al.* point out, that these primates are born as stable, bone-marrow-chimaeric twins may be relevant. This might help to compensate for the negative effect of the polymorphism of class I molecules expressed on the trophoblast; females might be tolerant of other parental haplotypes and would therefore be less likely to reject a fetus that carried a foreign MHC class I type.

We need to know therefore if the trophoblast cells in the tamarin express the same class I products as other tissues, or if they show limited or quite different expression. It will also be worthwhile to look more closely at other species that show limited MHC class I polymorphism, perhaps for different reasons (for example the cheetah[10] and the Syrian hamster[11]), to see if there too evolutionary pressures have acted in a similar way. ☐

ORGANIC CHEMISTRY

New routes to natural products

John Mann

AT one time, the synthesis of complex molecules was the noblest pursuit for an organic chemist. During the past ten years, however, many organic chemists have been lured by the fat research grants and contemporary glamour of bio-organic chemistry. So it is good to see two excellent examples of natural-product synthesis reported by Ley *et al.*[1-7]. The biological interest of one of the compounds (*myo*-inositol 1,4,5-triphosphate (IP$_3$)) is well known, but that of the other (the anti-parasitic agent avermectin B1a), is also considerable.

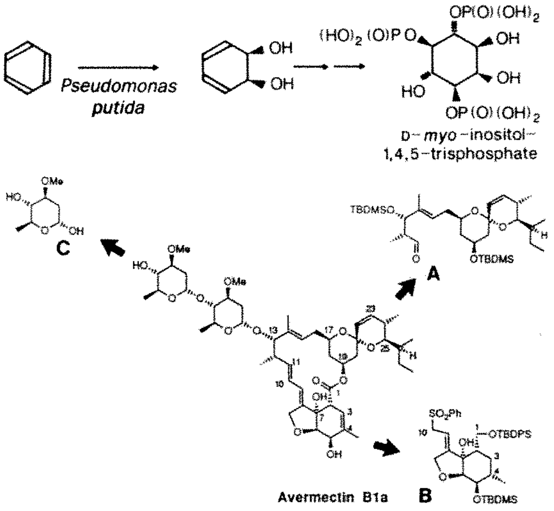
There has been enormous interest in the inositol phosphates, in particular the role of IP$_3$ as a second messenger, ever since their involvement in intracellular signalling was first proposed by Mitchell[8] in 1975. A number of syntheses of both the natural compounds and certain analogues have been described, but almost all of these commence with *myo*-inositol and proceed via a tortuous sequence of hydroxyl-group protections and deprotections in order to establish the desired phosphorylation pattern. Ley's approach[1-3] is conceptually different in that *cis*-3,5-cyclohexadiene-1,2-diol is used as the starting material (top in figure). This is produced from microbial oxidation of benzene by *Pseudomonas putida* and is thus cheap and readily available.

The remaining hydroxyl groups are introduced in a regio- and stereocontrolled manner to produce IP$_3$ and a large number of analogues. This new route is concise, does not use expensive or esoteric reagents, and provides access to the racemic forms of the compounds, or the pure enantiomers (both natural and unnatural) with only minor modifications. The approach makes a novel range of IP$_3$-related compounds readily accessible for biological investigation.

The avermectins are mould metabolites first isolated in 1976 from a strain of *Steptomyces avermitilis*[9]. They were shown to have high potency and broad spectrum of activity against animal parasites. The compounds seem to act at GABA receptors and to maintain the chloride channels in the open form, thus potentiating the inhibitory activity of GABA at neuronal junctions. Several avermectins are now produced routinely using fermentation technology, and ivermectin (the dihydro-analogue of avermectin B1a) is at present sold in more than 60 countries worldwide for the control of both internal and external parasites of livestock.

Notwithstanding this availability, the compounds are challenging targets for synthesis. Avermectin B1a, for example, has 20 stereocentres and a host of delicate functional groups; and to probe the biological activity of these interesting molecules, selected analogues must be prepared. Several research groups have accepted the challenge, but only one complete synthesis[10] of an avermectin has been reported previously.

Ley's new route[4-7] (bottom in figure) has the advantages of both conciseness and convergence of the various synthetic routes. The innovative chemistry devised to solve particular synthetic problems is the most interesting aspect of the work. Highlights include the use of organo-iron chemistry to produce not only the key spiroacetal (**A** in figure) but also the oleandrose subunits (**C**); and the coupling of the fragments **A** and **B** to form the aglycone. The final steps of the synthesis were achieved with the minimum of protection/deprotection of hydroxyl groups by an elegant exploitation of the selective reactivities of these groups. The overall route is flexible enough to allow for the synthesis of analogues, and should be of great value for further biological investigation of the way that these compounds work. ☐



Synthetic schemes to two natural products (see text).

OCEAN DRILLING PROGRAM

Evolution of the Japan Sea

Leg 127 and Leg 128 shipboard scientific parties

LEGS 127 and 128 of the Ocean Drilling Program spent the summer and early autumn of 1989 drilling at six sites in the Japan Sea (see figure). The goals of these two expeditions aboard the RV *JOIDES Resolution* were to assess the timing, style and dynamics of the opening of this sea and to decipher its subsequent palaeoceanographic evolution.

The western Pacific region is characterized by a series of marginal basins bordered by many island arcs. The formation of these marginal seas is intimately linked to the subduction of oceanic crust at adjacent deep-sea trenches. This process fuels the volcanic arcs and creates new oceanic crust and marginal seas through sea-floor spreading and faulting in the back-arc areas between the subduction zone and the continent. The Japan Sea is a large back-arc basin with water depths greater than 3,500 m, separated from the adjacent Pacific Ocean by shallow bathymetric sills of less than 150 m depth. The geology and geophysical structure of the Japanese Islands point to the presence of continental crust beneath the Japan arc, which in turn calls for a history involving continental rifting and separation of the arc from mainland Asia through back-arc formation of the Japan Sea — a tectonic scenario thought to be responsible for the evolution of many ancient continental margins.

Sixteen years ago, Leg 31 of the Deep Sea Drilling Project (DSDP) attempted to study the history of the Japan Sea but failed to penetrate the sedimentary cover and sample basement rocks, thus leaving many fundamental questions unanswered. So the highest priority of Legs 127 and 128 was recovery of basement rocks, which should record the earliest phases in the evolution of the sea. Leg 127 drilled four locations in the Yamato and Japan basins (sites 794, 795, 796 and 797), where rocks that represent acoustic basement on seismic reflection profiles were penetrated for the first time and complete overlying sedimentary sections were recovered. Leg 128 followed by drilling at two topographic highs on the sea floor, including site 798 on Oki Ridge which yielded a key Pliocene and Pleistocene palaeoceanographic reference section for the sea and an unusually clear record of explosive volcanism during this period. Site 799 was located in the Kita-Yamato Trough, a sediment-filled graben (rifted valley) which splits the Yamato Rise. This trough is thought to represent a failed rift within a fragment of continental crust that was isolated during initial back-arc spreading. It is thought to be an ideal setting for the formation of volcanigenic massive sulphide deposits, and it represents the first CDP site selected specifically to test ideas about deep-sea ore genesis. Drilling at this site produced a sequence representing the Lower Miocene through to the Holocene, which will enhance our understanding of metalliferous back-arc environments. Leg 128 also returned to site 794 in the northern Yamato Basin to perform two downhole geophysical experiments designed to probe the structure and character of the crust and upper mantle beneath the Japan Sea.

Drilling by Leg 127 at sites 794, 795 and 797 established that the volcanic basement rock encountered at these sites is of Lower Miocene age. Lithological sections representing acoustic basement at site 797 included interlayered coarse turbidite sands and basalt sills and flows, whereas the basement at site 795 was formed from brecciated basaltic lavas. Thus these facies probably explain the thick oceanic crust indicated by seismic velocity profiles beneath the Yamato Basin. The combined drilling of Legs 127 and 128 at site 794 penetrated 190.5 m into a basal series of stacked tholeiitic dolerite and basalt sills and flows representing the early Miocene floor of the northern Yamato Basin. Deep-water microfossils recovered from small sediment sequences intercalated within volcanic rocks at site 794 attest to the rapid subsidence of the Yamato Basin shortly after initial back-arc rifting, a process confirmed by the results from sites 797 and 799. Indeed, all evidence obtained by Legs 127 and 128 indicates that the Yamato Basin was formed by extremely rapid subsidence during the early Miocene (probably before 19 Myr ago) accompanied by intense volcanic activity.

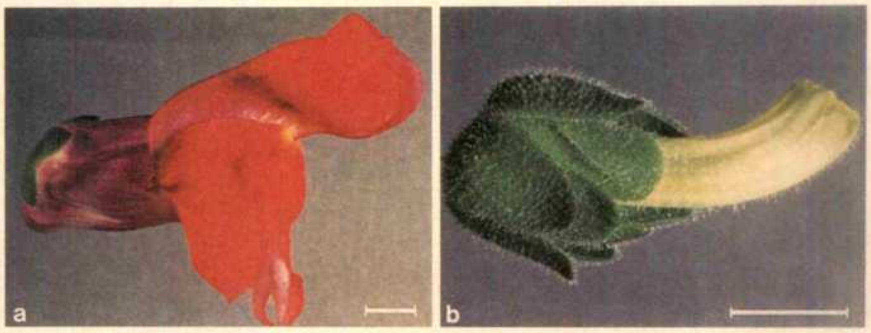
The sedimentary sequences overlying basement rocks at all six sites in the Japan Sea show striking regional similarities and form five distinct lithological associations which record major tectonic and palaeoceanographic changes during evolution of the sea. These include (1) Lower Miocene delta-front sands and siltstones rich in plant debris, which were deposited rapidly during initial back-arc rifting and basin subsidence; (2) widespread Middle Miocene siliceous and carbonate-rich hemipelagic claystones and volcanic tuffs, marking a period when the rate of basin subsidence outpaced the rate of sediment accumulation in the sea; (3) Upper Miocene claystones and porcellanites; (4) Pliocene diatom oozes representing evidence of climatic cooling, upwelling and increasing primary productivity in the sea; and (5) light/dark rhythmic Plio-Pleistocene sediments, reflecting rapid oscillations in the oceanographic behaviour of the Japan Sea from stagnant, near-anoxic conditions to the fully oxic and hyperventilated conditions exemplified by the sea at present. Significantly, the latter cyclic sequences are best developed in the upper Pleistocene sediments which represent the past 400,000 years, during which time basin sills and climatically induced periods of low sea level may have periodically isolated the Japan Sea from the open Pacific.

The relatively recent tectonic emplacement of shallow bathymetric sills or straits separating the Japan Sea from the Pacific Ocean is one manifestation of a convergent plate boundary apparently developing along the eastern margin of the sea, as evidenced by uplifted en echelon ridges, thrust faults and large compressional earthquakes. Leg 127 drilling at site 796 revealed that gravity-driven deposition filling the northwestern Japan Basin stopped, and uplift of the Okushiri Ridge above the basin floor subsequently

Changing the flowers

WITH the report by Sommer *et al.* of the cloning of the snapdragon *deficiens* gene (*EMBO J.* 9, 605–613; 1990), and that by Yanofsky *et al.* of the cloning of the *agamous* gene in *Arabidopsis thaliana* (page 35 of this issue), the study of plant development has taken a big step forward.

The picture, reproduced from the *EMBO Journal*, shows (a) a normal flower of the snapdragon (*Antirrhinum majus*), and (b) one produced by a plant with a mutation at the *deficiens* locus. The petals of the mutant flowers are replaced by a second ring of sepals, the leaf-like organs that form the outer whorl of flowers of this kind, and the stamens are transformed into carpels, which form the tubular structure protruding from the two rings of sepals.



Like *deficiens*, *agamous* is classed as a homeotic gene, because its mutations cause the transformation of one type of flower organ into another. But the effect of *agamous* mutations is quite different from that of *deficiens* mutations: the six stamens of the mutant flowers are replaced by six extra petals, and the carpels are replaced by a whole new flower. The new flower suffers from the same homeotic transformation, so that a repeating pattern of sepals and petals is generated.

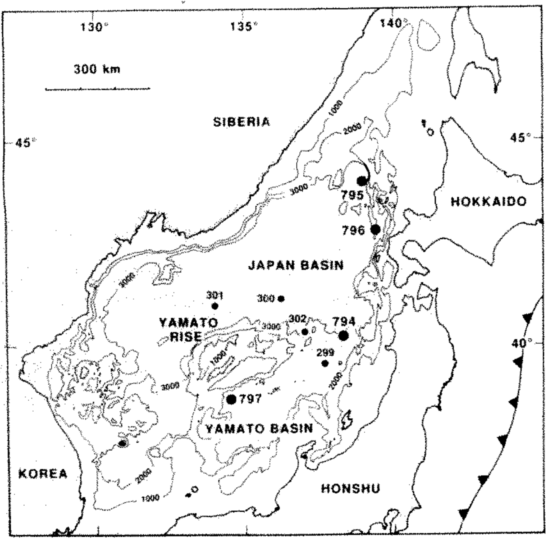
The normal flowers of both snapdragon and *A. thaliana* consist of four concentric whorls of organs: an outer whorl of sepals, followed by whorls of petals, stamens and finally carpels. The mutations that cause transformations of these organs differ in important respects from the better-known homeotic mutations of the fruitfly *Drosophila melanogaster*. The fruitfly homeotic mutations cause discrete transformations of one segment of the fly's body into another, so that a segment is exactly replicated and the segment number is not changed; in the *agamous* mutation, by contrast, the number of petals in the transformed third whorl is six, the same as the number of stamens that would normally be present in this whorl, and not the four that would be expected by a precise reiteration of the second whorl.

The sequences of the *deficiens* and *agamous* protein products show a region of roughly 56 amino acids where they are very similar, both to one another and to two known transcription factors, human serum response factor and the yeast protein MCM1. In the case of serum response factor at least, the conserved region is known to fall within the DNA-binding domain of the protein. So the strong presumption is that flower homeotic gene products form a class of DNA-binding regulatory proteins linked by their similar DNA-binding domains, much as the fruitfly homeotic genes are linked by their 'homeobox' domains.

Geoffrey North

began, in the latest Pliocene (1.8 Myr ago), at the same time that widespread deformation occurred along the entire eastern margin of the Japan Sea. This activity might represent an initial stage in the now continuing compressive destruction of the sea.

Although deep-sea drilling has been very successful in unravelling ocean history by allowing direct study of rocks and sediments in cores, the technique is limited to the upper 1.5 kilometres of ocean crust. Leg 128 carried out two multiship geophysical experiments at site 794 that bridged the gap between direct observations of the upper crust from drilled cores and remotely sensed data on the structure of the deeper crust and upper mantle. The Japan Sea was ideally suited to these experiments because the structure of the deep crust and mantle varies laterally from the Pacific plate (in front of the subduction zone) through the Japanese Island arc to the Japan Sea behind it. These variations reflect the dynamics of the subduction process.



Map of the Japan Sea, showing locations of ODP Leg 127 sites (dots), Leg 128 sites (circled dots) and DSDP sites (triangles). ODP site 794 was occupied during both Legs 127 and 128. Bathymetry in metres.

The first experiment involved installation of a specially designed digital broadband seismometer at 715 m below the sea floor in volcanic basement rock. The emphasis in this experiment was on long-period signals, which probe larger scales and deeper structure. Following an experiment that essentially monitored instrument performance and analysed local crustal structure, the seismometer is now accumulating long-term data on natural earthquakes, which will ultimately be used to create a three-dimensional image of the crust–mantle configuration in this region.

The second experiment comprised active-source electrical measurements designed to give high-vertical-resolution profiles of the electrical resistivity in the crust and upper mantle. Resistivity measurements can yield information on crustal temperatures and the presence of fluids or partial melts. Resistivity observations at site 794 were made by placing an array of electrodes in a drilled hole and having a supporting ship apply an electrical charge to the water column at increasing distances from the drill hole. The results will yield new estimates of electrical resistivity to a depth of 10 km beneath the Japan Sea.

The results as a whole indicate that the marginal basin of the Japan Sea seems to be in a mature stage of evolution despite its recent birth in the late Oligocene to early Miocene. Indeed, the relatively young age of the sea has allowed all of the key elements in the back-arc spreading process to be deduced from samples of sea-floor basalts and sediments, along with the history of the water mass.

Although the data collected during Legs 127 and 128 have yet to be fully analysed, it is clear that the Japan Sea now stands as one of the best documented back-arc basins in the world and provides a potential model for interpreting the rifting and mountain-building processes that characterize many modern and ancient continental-arc settings. ☐

DAEDALUS

Sun and air

One of the neatest ways of trapping solar energy is the solar pond. This contains ordinary water, with a layer of denser salt water underneath it. The slow upward diffusion of the salt produces a stable density gradient in the pond; convection cannot occur. Solar radiation penetrates the water and is absorbed by the blackened bottom of the pond. The heat cannot convect upwards; it leaks upwards by conduction only slowly; the bottom of the pond can almost reach boiling point.

In this connection Daedalus recalls the Valley of Death in Java, into which carbon dioxide is steadily released from some subterranean volcanic source. The gas forms a layer on the valley floor. Men and animals who enter the valley (except, possibly, giraffes) are suffocated. But plant life flourishes luxuriantly.

Gases, especially heavy ones, have even lower thermal conductivities than liquids. So, says Daedalus, a gaseous nonconvecting 'solar pond' on the Valley of Death principle should be even more efficient. DREADCO's engineers are now converting an empty reservoir into a prototype. They are roofing the top with a supported web of transparent sheeting, and the bottom with reflective aluminized film. They will then pour carbon dioxide, or some even heavier gas, over the floor of the reservoir. A grid of blackened absorber pipes, supported just off the bottom, will be heated by solar radiation entering from above and reflected from below, while being excellently insulated by the surrounding nonconvective density-stratified gas. It will heat up until convection can just overcome the density gradient against it.

With carbon dioxide, this should happen at 180 °C; sulphur dioxide could give 390 °C and dichlorodifluoromethane could give almost 1,000 °C. Although these limits are unlikely to be reached in practice, the solar gas-pond could clearly generate high-grade heat and power while providing a splendid and ecologically virtuous dumping ground for gaseous industrial nasties. It would, of course, slowly lose efficiency as the stratified gas diffused towards uniform composition. Fortunately, the diffusion-time increases as the square of the mixing distance. A solar gas-pond 40 metres deep would take years to mix completely. Slow removal of the central stratum, while feeding in fresh heavy gas at the bottom and air at the top, could maintain the density gradient indefinitely.

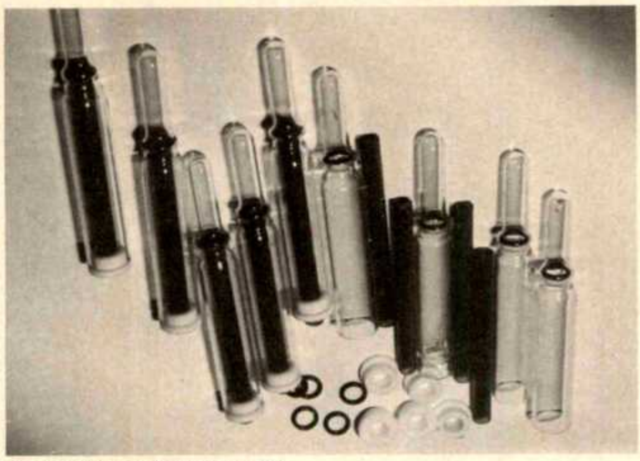
A carbon dioxide solar gas-pond should also act as a wonderful forcing house for tropical vegetation. Its high temperature and insect-suffocating, photosynthesis-encouraging atmosphere should enable coconut palms and breadfruit trees to flourish effortlessly in the bleakest of temperate zones.

David Jones

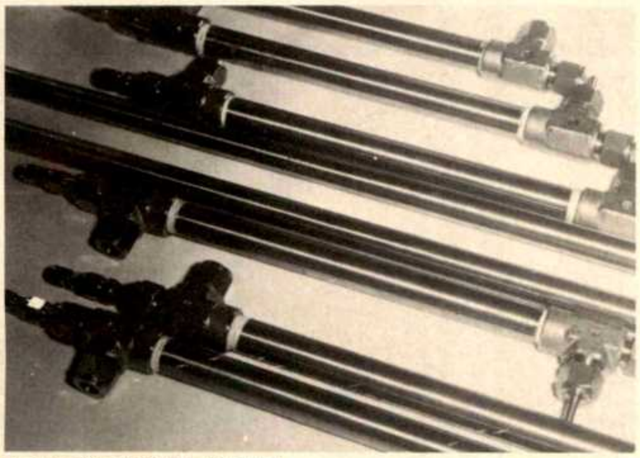
A VERSATILE INORGANIC MEMBRANE PROCESSING

Yours : THE NEED [FROM SMALLEST TO LARGEST]
Ours : THE ANSWER [EVERY-TIME]

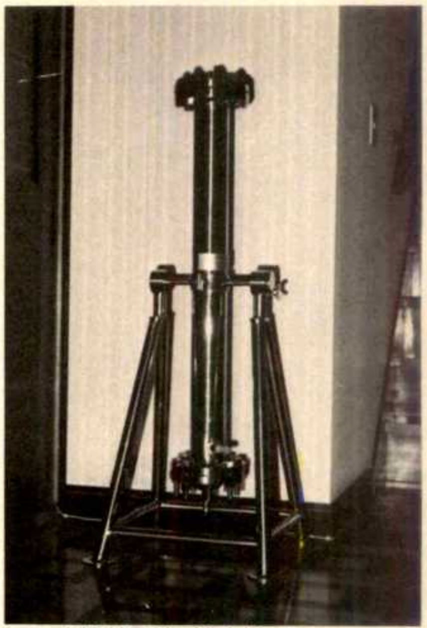
Now we can provide upgraded INORGANIC MEMBRANES of various pore sizes from 3Å to 200Å for the first time in the industry. Our new membranes can achieve adsorption and desorption independently which has been impossible with conventional Chromatography or Pressure Swing Adsorption. Furthermore, pore surfaces can be modified for the better control of mass-transfer according to intended use. With this membrane system, you can overcome the pollution problems and improve the efficiency of your distillation, evaporation, crystallization, drying, condensation and other heat-consuming processes.



Smallest (Conical Bottom Tube)
UF membrane installed in 17.00㎜φ PYREX conical bottom tube.
Suitable for about 2000 rpm centrifugal evaporator.



Medium (Single Tubler Module)
36 inches and 18 inches length single tubler module within stainless jacket tube.
Excellent at operation of tube pump (Peristaltic). Complete system kit also available.



Largest (Multi-Tubler Module)
In making large labo-plant, we can provide a custom product according to your order using our MTM.

BAEKONIZATION SUBSTITUTES

MICROINJECTION

ELECTROPORATION

COMPARISON

	BAEKONIZATION[1]	*MICROINJECTION*[2]	*ELECTROPORATION*[3]
TRANSFER EFFICIENCY[4]	200 embryos/min	2 embyros/min	200 embryos/min
VIABILITY[5]	90%	70%	<5%
INTEGRATION[6]	40%	25%	0
EXPRESSION[7]	yes	yes	no

[1] Transfer of macromolecules into biological systems by *BAEKON2000* instrument.

[2] Standard microinjection procedure.

[3] Electroporation refers to the treatment of DNA/embryos mixture by a capacitor-based electroporator where both anode and cathode are in direct contact with the sample.

[4] Transfer Efficiency refers to the number of embryos* that can successfully be transferred per unit time.

[5] Viability refers to the survival rate of embryos post-treatment.

[6] Integration refers to the percentage of fish that shows positive hybridization between the DNA from baekonized fish and the DNA probe.

[7] Expression refers to the expression of a growth hormone gene in the transgenic animal.

*Zebrafish

BECAUSE BAEKONIZATION...

1. Facilitates **homogenous** macromolecule transfer into **many** cells, oocytes, fertilized eggs, and spermatogenic cells;
2. Permits transfer to a large group of embryos at the **same** developmental stage;
3. Takes less than 1 minute to transfer millions of cells or hundreds of oocytes or fertilized eggs **simultaneously**;
4. Does **not damage** target cells or **alter** the intracellular environment;
5. Allows **co-** *and* **sequential** transfer of both protein and DNA molecules into target cells, in different combination and permutation, to program gene expression;
6. Results in **expression** and **functioning** of macromolecules inside the baekonized cells, oocytes, or fertilized eggs; and the **integration** of exogenous DNA into the genome.

Brilliant pebbles won't do

SIR—In their recent Commentary[1], G. Canavan and E. Teller conclude that singlet space-based interceptors (SBI) are ". . . effective in the near-term and mid-term . . ." and that they can be made adequately survivable against achievable Soviet reactions by "hardening, evasion, and decoy in combination . . .". These conclusions stem from the constraints imposed by the authors on the Soviet response. Unaccountably, they assume the Soviets will be able to reduce missile burn time T only to 300 seconds or so. But the Soviets already deploy SS-25 missiles with $T = 180$ seconds, corresponding to an availability of 1.1% for the SBI. Subtracting the SBI "release time" of 50–100 seconds would further reduce the effectiveness of SBI, according to Lt Gen. George L. Monahan's formal response to the US Senate Appropriations Committee on the SDI programme.

Ten warheads deployed on silo-based single-warhead SS-25s within a region a few hundred kilometres or less across would require 10/1.1% = 900 brilliant pebbles to be able to assign even a single interceptor to each missile. As few as 1,000 ICBM warheads would thus need 90,000 brilliant pebbles — a clear demonstration that the defence is not cost-effective at the margin.

The Senate Appropriations Committee went on to ask whether the SDI phase I architecture would be capable of destroying more than a few SS-25s in the boost phase. Monahan answered "No. The phase I SDS (Strategic Defense System) does not provide continuous coverage of the SS-25 deployment region given the available time (SS-25 burn time minus surveillance/command and control timeline)."

If the burn time of a new solid-fuel missile were reduced to $T = 100$ seconds, there would be no intercepts at all. The launch weight of a booster designed to deploy its single warhead in 100 seconds would be about 5% above that of a missile of normal burn time[2].

Canavan and Teller dismiss an even more important and less costly countermeasure: "Attrition during peacetime . . . While anti-satellites would be effective in that role, their use might be viewed as an attack, so the main danger in this case would probably come from ground-based lasers." But the Soviets already launch hundreds of test missiles a year without our viewing them as an "attack". A deployment of SBI could provoke the building of a similar number of Soviet small ASAT weapons, with 40-kilogram homing warheads. Only about 3.5 kilometres per second need be supplied by a two-stage rocket to lift the ASAT to 400-kilometre altitude at precisely the time an SBI is expected at the intercept point. Launching such a small, slow rocket in Kazakhstan could not be regarded as an attack on the United States; it could not reach us, but it could reach our space weapons overflying the Soviet Union.

The key points in making the ASAT clearly cheaper[3,4] and simpler than the brilliant pebbles are that the rocket mass required to launch a 40-kilogram ASAT homing head to intercept altitude is a factor of seven smaller than that required to launch into orbit a 40-kilogram SBI (bearing a 5-kilogram homing head), and the much easier task of an ASAT performing its job within full view of ground-based radar and optical sensors, designators and compound intelligence. This ground-based support would allow the ASAT to identify and destroy manoeuverable, decoyed SBI, or (equally effective) to provoke them to manoeuvere and dispense decoys so that they will be vulnerable weeks or months later.

If helpful, intercepts could be timed so that the intercept takes place in daylight while an observation point on the ground is in the dark. With a phase-I SDI deployment of 4,000 SBI, an SBI would fly within 50 kilometres of the vertical over the ASAT launch site about 20 times an hour, so there are many opportunities for intercept. A deployment of 40-kilogram brilliant pebbles could be defeated at much lower cost and thus would impair rather than add to US security.

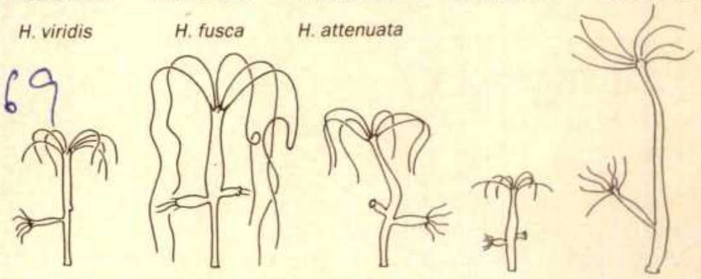
Identity crisis

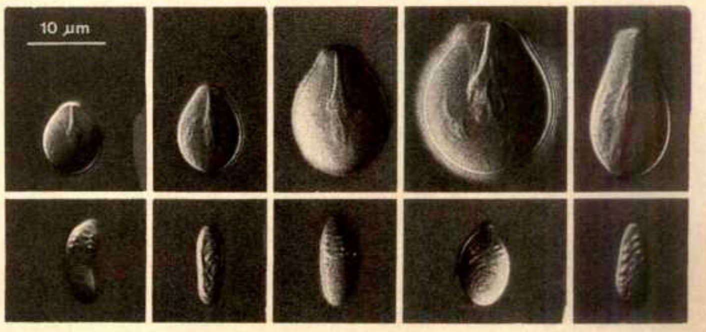
SIR—Hydra are used frequently in research and teaching[1,2], but identifying them is extremely difficult because names have been used inconsistently. Recent work has clarified the names and identities of the five species described in Europe[3-5]. The nematocysts ("stingers") provide the most certain means of identification, and the morphological characters of the body of hydra, as shown in the figure, provide simple guides for identifying the species. *H. viridissima* is immediately identifiable by its green colour, and *H. oligactis*'s identity is revealed by two precocious tentacles on young buds. Identification of the other three species on the basis of morphological criteria is more difficult because the lengths of the tentacles and body vary with culture conditions.

One reason for confusion among names is that the species of hydra most widely used in laboratory research has been

Correct binomial	*H. viridissima* PALLAS 1766	*H. oligactis* PALLAS 1766	*H. vulgaris* PALLAS 1766	*H. circumcincta* SCHULZE 1914	*H. oxycnida* SCHULZE 1914
Recent synonyms	*H. viridis*	*H. fusca*	*H. attenuata*		
Colour	green	brown			
Number of tentacles on young bud	5–6	2	5–6		
Length of body	moderate (5–10 mm)	large (8–15 mm)	moderate (5–10 mm)	small (3–7 mm)	very large (10–20 mm)
Length of tentacles relative to body	½–1	2–4	½–1	½–1	½–1

P 38,669





frequently and incorrectly called *H. attenuata*. This name is no longer considered valid and the species should be known as *Hydra vulgaris* Pallas 1766. Another reason for confusion is that all the European species of hydra have been known by a plethora of names, most of which have been applied to more than one species. The unruly nomenclature has obscured the fact that there are rather few species of hydra and that these are easily distinguishable.

Similar general types of hydra occur on all continents, although the names and the number of species varies. *H. oligactis* and *H. viridissima* are cosmopolitan. In North America, *H. littoralis* and *H. carnea* among others, and in Japan, *H. magnipapillata*, closely resemble *H. vulgaris* of Europe. *H. hymanae* and *H. utahensis* from North America are similar to *H. circumcincta*. Whether some of these are synonyms is not yet known.

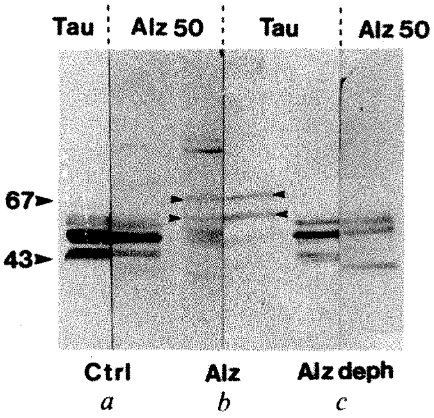
Tau marker?

SIR—The Alz-50 monoclonal antibody recognizes a neuronal antigen, termed A68, exclusively in Alzheimer brain tissue[1]. This antigen, of relative molecular mass 68,000 (68K), is also detected in the cerebrospinal fluid[2] and in the olfactive epithelium from patients with Alzheimer's disease[3], and it has been suggested that Alz-50 might help *in vivo* diagnosis. It was then shown that Alz-50 also cross-reacts with tau proteins[4], the main antigenic component of the paired helical filaments that accumulate in degenerating neurons during Alzheimer's disease, suggesting that A68 might be an aberrant form of tau. We have shown that two tau proteins of M_r 64 and 69K, tau 64 and 69, are specifically detected in brain areas affected by the neurofibrillary degeneration[5]. These proteins arise from an abnormal phosphorylation of tau, as demonstrated by the decrease in their mass after alkaline phosphatase treatment[5]. The crossreactivity of Alz-50 with tau proteins causes us to suspect that Tau 69 and A68 are the same protein.



Binding of Alz-50 and anti-tau on immunoblots of frontal cortex from a control (*a*) and a patient with Alzheimer's disease before (*b*) and after (*c*) alkaline phosphatase treatment. The dephosphorylation was performed as described in ref. 5, and details are available on request from the authors.

Alz-50 was reacted against immunoblotted total protein extracts from different control and Alzheimer's brain areas. These immunoblots reveal that Alz-50 is essentially directed against tau 64 and 69 (see figure) and that no protein other than the pathological tau proteins are detected in this molecular-mass range. The experimental dephosphorylation of tau 64 and 69 results in the formation of 50–60K products, which are still labelled by Alz-50. Immunoblots of two-dimensionally resolved proteins corroborate these findings.

Our results strongly suggest that A68 is an abnormally phosphorylated tau protein. Because the expression of tau 69/A68 is correlated with neurofibrillary degeneration and intellectual impairment[6], Alz-50 marker might be used to help diagnosis of the disease. Moreover, the further study of tau 69/A68 could help track the biochemical dysfunctions that lead to neuronal death and dementia.

Correction

In the Commentary article "Duesberg, HIV and AIDS" (*Nature* **345**, 659–660; 1990) it is said that homosexuals in the United States have a 900-fold higher risk of developing Kaposi's sarcoma. As stated in the same paragraph, the 900-fold higher incidence referred to HIV-positive homosexuals compared to HIV-negative homosexuals. ☐

Mutagen test

SIR—It is commonly assumed that environmental mutagens are responsible for most mutations in germline and somatic cells, and that mutations arising through endogenous processes such as depurination, deamination, replication error and transposition are comparatively infrequent. With the development of direct sequencing methodology, enough mutational events can be examined to address this issue more directly. Mutagens should produce different mutation patterns in populations exposed to different environments, as each mutagen has its own fingerprint of mutation[1]. By contrast, endogenous processes could produce an essentially invariant pattern of mutation. I find the spectrum of germline mutations from a particular sample to be similar to the spectrum of somatic mutations associated with the p53 and retinoblastoma genes, suggesting that endogenous processes are dominant in these cancers. I propose that tumour-suppressor genes could be useful epidemiological tools for determining the exceptions where environmental mutagens do predominate.

A meaningful comparison of the pattern of mutation requires genes where the observed pattern faithfully reflects the underlying pattern of mutation. From a population-based study of Caucasian families with haemophilia B residing in the midwestern United States and Canada (see table), we deduced[2] that the observed mutations do approximate the underlying pattern (corrected for biases of mutant ascertainment) of recent germline mutations in factor IX. A similar pattern of mutation occurs in Asians[3].

The tumour-suppressor genes offer an opportunity to examine the pattern of somatic mutation *in vivo*, without the artefacts induced by tissue culture. By contrast, dominant oncogenes, such as *ras*, are not good models for examining the pattern of spontaneous somatic mutation because only a few mutations will produce disease. Mutations in the p53 and retinoblastoma genes have recently been published (see table), and the pattern of somatic mutation in colon, brain, breast, and retina is similar to the pattern of germline mutation. Lung tumours are an exception to the general pattern ($P<10^{-4}$); most cases occur in smokers, exposed to enormous amounts of inhaled mutagens.

These data suggest that the underlying

DISTRIBUTION OF POINT MUTATIONS

	Germline cells			Neoplastic cells		
Mutational type	Factor IX Caucasians*	Factor IX Asians	p53 Colon	p53 Bn/Br	Rb Retina	p53/Rb Lung
Transitions	31	10	11	6	5	0
(Transitions at CpG)	(12)	(6)	(6)	(3)	(3)	(0)
Transversions	5	4	2	0	1	8
Micro-deletions/insertions	2	2	2	0	2	1
Ref.	2	3	4,5	5	6	5–8

*The data approximate the underlying pattern of germline mutation in factor IX. Transitions at CpG are elevated 24-fold relative to other transitions (ref. 2). When the subset of Caucasians with severe disease was compared with the Asian sample, the patterns were essentially identical. The excess of deletions in retina cells reflects the large and highly redundant nature of the retinoblastoma (Rb) protein. Five of the six base substitutions produce nonsense or splice junction defects, implying that the more numerous missense mutations are underrepresented because they generally do not cause disease.

pattern of germline or somatic mutation will commonly be the same. It seems most likely that there is a strong selective pressure for endogenous control of the mutational process, rather than a ubiquitous and prominant mutagen. For germline mutation, the rate may be constrained by opposing evolutionary forces. Too little germline mutation would result in extinction of the species, as the level of variation in the population would be insufficient to adapt to environmental changes. Conversely, more than the requisite amount would increase the morbidity of the species as virtually all disease has a genetic predisposition.

Sensing reducing gases

SIR—The recent report[1] of a novel thin-film electrochemical cell for energy conversion prompts us to describe some work we have been carrying out using a related concept for the purpose of detecting reducing gases such as hydrogen and carbon monoxide in air.

Our cell is shown schematically in Fig. 1. Its solid components are a porous oxide substrate (polymer substrates, as described in ref. 1 are also useful) and two electrodes of dissimilar metals which are deposited by d.c. sputtering. For an electrolyte we depend entirely on a film of moisture adventitously absorbed from the atmosphere onto the surface of the substrate between the electrodes. With electrodes of platinum and gold, respectively, and the cell exposed to air in the relative humidity range between around 20 and 100% at room temperature a substantial open circuit potential (up to 500 mV) is generated. Operation requires the presence of both oxygen and water vapour.

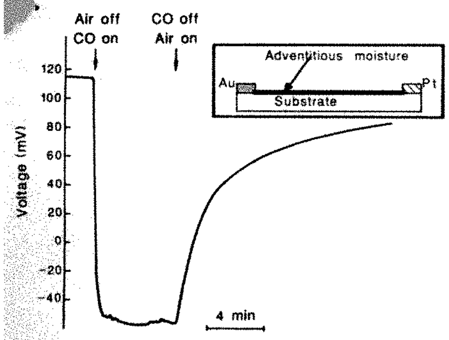

FIG. 1 Voltage response of WO_3 to 1% CO in air. Open-circuit potential from a cell based on a porous pellet of tungsten trioxide with platinum sputtered on to one flat surface and gold on the other. The potential difference was monitored via a Keithley model 614C electrometer with the platinum electrode connected as positive. The atmospheric compositional change between air and air containing 1% carbon monoxide at the points marked gave rise to a change of over 150 mV in the open circuit potential of the cell. Inset: schematic of the thin-film electrolytic cell.

The geometry of the three-phase interface involving a film of adsorbed moisture is ideally suited for sensing gas reactions: changes in open circuit potential result when the cells are exposed to small concentrations in air of a range of gases including hydrogen, carbon monoxide, ammonia, hydrogen sulphide and ethanol vapour (Fig. 1). The open circuit potential change of the cell increases approximately as the log of the concentration of the reducing gas in an air ambient (Fig. 2).

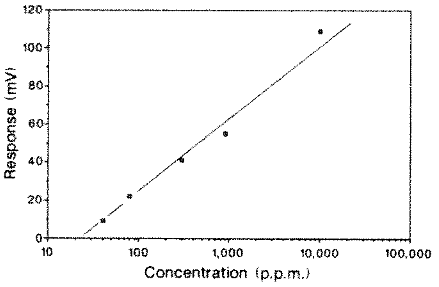

FIG. 2 Variation in the magnitude of the change in potential of a cell based on a porous pellet of tin dioxide, with one electrode platinum and the other gold as a function of the logarithm of the concentration of hydrogen in air.

We believe the mechanisms of response as involving changes in "mixed potentials"[2], which are different on different metals. An electrode at open circuit adopts a potential (mixed potential) such that the rate of all the anodic and cathodic processes balance. In air, in the absence of any other gases, the processes are the reduction of oxygen, and the reduction and oxidation of the metal:

$$\tfrac{1}{2}O_2 + H_2O + 2e^- \rightleftarrows 2OH^- \qquad (1)$$

$$Pt + 2OH^- \rightleftarrows PtO + H_2O + 2e^- \qquad (2)$$

$$Au + 2OH^- \rightleftarrows AuO + H_2O + 2e^- \qquad (3)$$

The balance between reactions (1) and (2) establishes a different potential from that between reactions (1) and (3), hence accounting for the open-circuit potential difference of the cell. The presence of a fuel gas such as CO introduced the possibility of a different reaction:

$$CO + 2OH^- \rightleftarrows CO_2 + H_2O + 2e^- \qquad (4)$$

which we surmise affects the mixed potential predominantly on the platinum electrode rather than on the gold, and hence gives rise to a change in the output of the cell.

As in the case of the thin-film electrolyte fuel cell[1], our device exhibits the convenient attributes of operating at room temperature and functioning without the need to separate the analyte (fuel) gas from the oxidant. The key role of reaction kinetics is also common to both applications.

For sensor applications the cell we have described offers a number of useful features: independence from the need for a reference volume leads to simplicity; room-temperature operation renders the detection of potentially flammable gases such as hydrogen a safer prospect and the open circuit potential in air provides a useful 'condition safe' indicator.

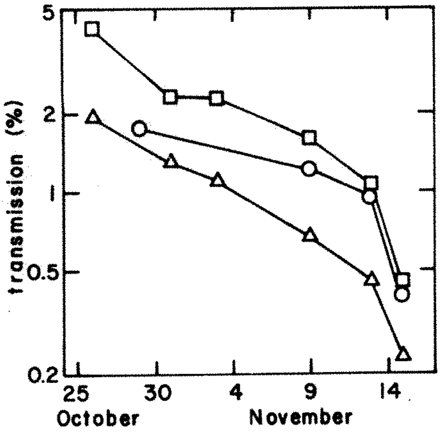
Radiation risk

SIR—There is a significant increase of ultraviolet levels in the Antarctic during the presence of the 'ozone hole'[1], and consequently there is concern for Antarctic life forms which may have developed only minimal defences against this radiation[2,3]. We have previously pointed out[4] that the problem is potentially most acute under the vast sea ice cover surrounding Antarctica, for the sea ice is particularly transparent when the ozone hole occurs. Because we did not know the ultraviolet properties of the ice, our argument relied on an extrapolation from data in the visible part of the spectrum. Here we report measurements showing that the transmission of sea ice shows an even larger seasonal variation in the ultraviolet than in the visible spectrum.



Seasonal development of the transmission of sea ice at wavelengths of 300 nm (ultraviolet-B, triangles) 350 nm (ultraviolet-A, squares) and 650 nm (mid-visible, circles).

The experiments were performed on 1.7-m-thick first-year sea ice in McMurdo Sound, using a technique described elsewhere[5]. The measured development of the transmission of the ice at three wavelengths is shown in the figure. All three curves show a substantial decrease during the spring, resulting from the development of a turbid surface layer left behind after brine pockets in the ice drain[6]. Surprisingly, the development is stronger in the ultraviolet than in the visible, for which we do not yet have a satisfactory explanation.

Algae residing near the ice–water interface are the first major biological population to experience the radiation entering the ice. These algae have been estimated to account for up to 30% of the primary food production in the ice covered regions of the southern ocean[7], and they are known to be sensitive to ultraviolet radiation[2]. We have estimated the level of flux falling on these algae as the product of the sea ice transmission of the figure and the surface flux measured at Palmer Station during the 1988 spring[1]. In the latter half of October, the under-ice flux rises as high as 10^{-3} W m^{-2} in a 10-nm band centred on the more damaging ultraviolet-B region, up from about 0.3×10^{-3} W m^{-2} before the appearance of the ozone hole. The 1988 ozone depletion was rather weak, and for the stronger depletions of 1987 and 1989 the October under-ice flux in the same band[8] would rise to about 5×10^{-3} W m^{-2}. Later in the season, the turbid surface layer shields the ice, so that in the height of summer the flux in this band is very much lower, about 5×10^{-5} W m^{-2}. Thus the yearly dose at the base of the ice is overwhelmingly dominated by the October flux, with the consequence that the ice algae will have experienced more than a tenfold increase of ultraviolet-B dose in recent years compared to the pre-1975 levels.

Cortical maps

SIR—Durbin and Mitchison[1] suggest an explanation for cortical maps and their distortions. If their purpose is to explain the biological conditions for the formation of two-dimensional brain maps, a theoretical description of the lateral interactions between neural cells would require the use of spatio-temporal partial differential equations[2,3]. But to implement powerful artificial 'neural' computing structures (which can form dimensionality-reducing mappings and abstractions), the self-organizing process is better described by computational algorithms that simultaneously update sets of neighbouring neural units[4].

Contrary to what Durbin and Mitchison claim, the equation they use (see their legend to Fig. 2) is not based on Hebb's law of synaptic plasticity; the first term would need a more lengthy justification[5]. Their second term was introduced "to make neighbours have similar receptive fields", but they did not explain what kind of biological adaptive process would account for this effect. This term in fact seems to stem from the physical analogy of stress–strain relations in an elastic ring or net[6]. In the other works cited by Durbin and Mitchison, on the other hand, lateral interaction has been used to activate neighbouring cells to learn from the same input, which is a different and natural assumption.

T. KOHONEN

Helsinki University of Technology,
Rakentajanaukio 2 C,
SF-02150 Espoo, Finland

DURBIN AND MITCHISON REPLY—As Kohonen points out, self-organizing models have previously been used to simulate cortical maps. We did not intend to suggest the contrary, and we did, in fact, cite Kohonen's book and Swindale's work. However, we should perhaps have spelt out more clearly the ancestry of our simulation. Of course, the main goal of our paper was to consider wiring minimization as an organizing principle for maps of many variables, and to relate this to self-organizing models. We believe this is a new approach to cortical mapping.

We are surprised at Kohonen's rather critical comments about the self-organizing model we used, since it operates in a similar fashion to his own. Both work at a fairly abstract level, which we believe was appropriate for our paper. As he remarks, the first term in our equation, though not directly hebbian, can be derived from Hebb-like interactions. Our second term can be justified in a similar way, by averaging neighbour interactions of the sort he describes; the 'elastic net' analogy is only intended to give intuitive guidance on the way the model works. The resulting equation has the advantage of a cleaner mathematical form which can be analysed in detail[7]. Empirically, it gives results similar to his and other self-organizing models, and in our hands is certainly no less computationally effective.

Outstanding high performance gel filtration for the '90s

Superdex™ 75 HR 10/30: The resolution is quite simply unbeatable, while column degeneration and leakage are a thing of the past.

Designed for both routine analysis and semi-preparative scale separations of low molecular weight proteins and peptides, Superdex 75 HR 10/30 from Pharmacia LKB represents a breakthrough in high performance gel filtration for FPLC® and HPLC.

The unique, composite matrix, Superdex 75, combines the excellent gel filtration properties of dextran with the physical and chemical stability of highly cross-linked agarose. The improved selectivity of the 13 µm matrix in the range 3 000-70 000 MW is ideal for separating monomeric and dimeric forms of recombinant proteins and peptides, for example, where baseline separations can be expected.

With Superdex 75 HR 10/30, you can use flow rates of up to 1.5 ml/min (that's 110 cm/h!) giving high resolution separations in less than 20 minutes. You can also use aggressive cleaning agents such as 1 M NaOH and 0.1 M HCl to ensure reproducible performance and long column life.

For outstanding performance in the '90s, choose Superdex 75 HR 10/30 from Pharmacia LKB.

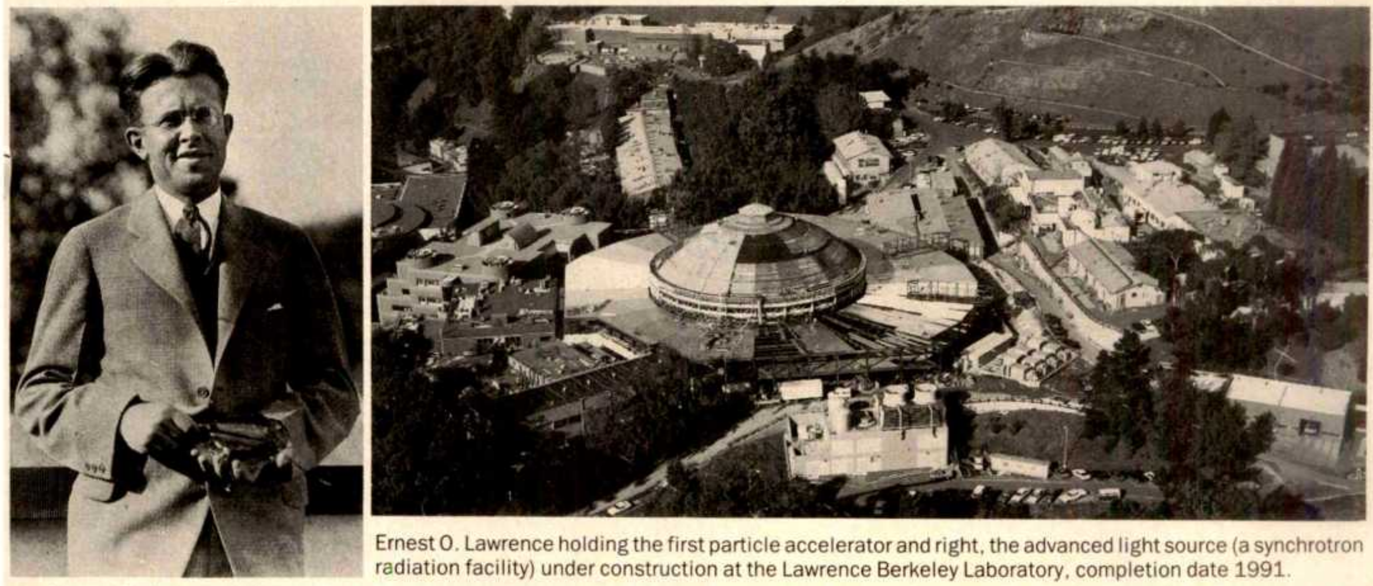
One man and his lab

John Stachel

Lawrence and His Laboratory. A History of the Lawrence Berkeley Laboratory. Vol. 1. By John L. Heilbron and Robert W. Seidel. *University of California Press: 1989. Pp.586. $29.95.*

An understanding of just how high-energy physics reached its present state of apparently limitless demands on the world's physical and financial resources — as well as on the human resources of many physicists — can well begin with a close scrutiny of "the rise of Big Science as it was born in the Rad Lab" (Martin Kamen, *Radiant Science, Dark Politics*). Those of us who are not technological determinists want to get a sense of how the nuclear physicists of the 1930s, through cooperation and conflict with their fellows and with the rest of their social milieu, created the first generation of particle accelerators; and how the result in turn helped to shape the lives and deeds of succeeding generations of particle physicists. We want to get a sense of the alternatives that were faced, the crucial choices that were made — and why — and of potentialities left unexplored as a consequence of these decisions. Heilbron and Seidel have in large measure succeeded in fulfilling these hopes in the first volume of a projected trilogy, which carries the story to 1941, the year of America's entry into World War II.



Lawrence Berkeley Laboratory

Ernest O. Lawrence holding the first particle accelerator and right, the advanced light source (a synchrotron radiation facility) under construction at the Lawrence Berkeley Laboratory, completion date 1991.

We watch Lawrence himself pick up the basic idea for the cyclotron, which had previously occurred to many people, and develop it into a working machine, using his enthusiasm, energy and considerable skills as an organizer to build up a remarkable group of doctoral students and postdoctoral co-workers — his "boys" in the typical male-bonding language they all used. Heilbron and Seidel emphasize that, if Lawrence "himself had not uncovered much new about the nucleus", his "notable contribution" was "the cyclotron laboratory" (p. 489). As Livingston, one of the first and most notable of the boys — and one of the first to break free of Lawrence and his lab — put it: "His optimistic and inspirational attitude was what convinced me it was worth working on" (p. 486).

Yet Lawrence himself was changed by the course of his own success. The process of reaching for ever-higher energies and ever-bigger machines seems to have become an end in itself for him, an imperative only loosely coupled to uses to which the beams emerging from his machines could be put. "Lawrence sets goals expressible not in terms of progress in physics, but in terms of increases in decimals" (p. 480). While Lawrence and his brother John, a physician who worked on medical applications of the newly available particle beams, were undoubtedly sincere in their efforts to benefit humanity ("It means a great deal more to civilization . . . to find a new radiation or a new substance that will cure disease than it would to discover a new supernova", Ernest said in 1940), there was just as undoubtedly an element of manipulation in the way these prospects were dangled before prospective donors — and the general public — as a means of obtaining the financial support that became more and more necessary to the realization of Lawrence's ever more ambitious dreams. He was forced by the logic of his position as an experimentalist who had staked his whole career on the building of ever bigger and more elaborately instrumented cyclotrons to become the intimate of university administrators, foundation nabobs and influential industrialists. His induction into the Bohemian club, a retreat for the rich and powerful of San Francisco and their university confrères, fairly early in his career at Berkeley can be taken as an early indication of his success. The award of almost one-and-a-half million dollars by the Rockefeller Foundation and the trustees of the University of California in 1939 marked the culmination of his efforts: "The munificent grant represented many things: dollars to be sure, but also the affection, respect and confidence in which Lawrence's fellow physicists and prominent men of business held him" (p. 482).

For the first time, funding for nuclear physics began to rival that for an older American mania for the super in science, big telescopes; the parallel with the 200-inch telescope was explicit in the funding hype for the cyclotron — "the Palomar of the vanishing small". By this time, almost all the main ingredients for contemporary big science were in one place, except one: large-scale financial support from the federal government. As the authors indicate in the last chapter, World War II was to provide that ingredient.

The change in Lawrence was not without its costs to the laboratory and to the man. A veteran of the lab in the 1930s, Morton Kamen, reports that Lawrence "was almost always on the road by 1939. The early magic of the Rad Lab had largely vanished", to be replaced by "a new, less personal ambience, unpleasant in its demands for aggrandizement". Another ingredient had been added to the recipe for a modern high-energy physics facility. Kamen connects Lawrence's "untimely death at the age of fifty-seven of [chronic] ulcerative colitis" with the inflexible demands that he came to make on his family, his lab and himself. There are few hints of this darker side of the Lawrence story in the present volume, although we may anticipate more in the sequel.

Lawrence's ambitions were not only intensive — the biggest machine possible — but also extensive: "There should be a cyclotron lab in every university center" he said in 1938. He generously exported the know-how — and the people who knew how — to physics centres in the United States and abroad. By 1940, "there were 22 cyclotrons completed or under construction in the United States" (p. 308), hardly enough to satisfy Karl K. Darrow, the Polonius of American physics, who opined: "The country may need a thousand cyclotrons" (p. 311).

One gets a sense of lost potentialities for other modes of development of nuclear physics from the initial resistance to the spread of the cyclotron by the best of the British and finest of the French nuclear physicists. Lawrence was often reproached for careless work and unjustified claims in the early years of the lab, such as his notorious argument for the supposed instability of the deuteron. Heilbron and Seidel make a rather harsh assessment: "The frequency with which the laboratory had to retract published results had declined since Lawrence had gone full time into fund raising and administration" (p. 385). In any case, it is certainly a "disagreeable fact that no major discovery had yet been made [by 1940] in any cyclotron laboratory".

The great discoveries in nuclear physics in the 1930s were made by small groups, getting the most out of small accelerators, careful chemical analyses and free-of-charge cosmic rays. No wonder Rutherford and Chadwick, Cockcroft and Joliot-Curie initially resisted the call from California. In another preview of post-war things to come, the first foreign converts to the Berkeley gospel were the Japanese, based on "a conviction on the part of government and industry that excellence in Western science was essential to Japan's place in the sun" (p. 317).

The need to move to higher energies than conventional methods could reach impressed itself on British, French and German savants in the late 1930s; by this time, the initial quirks that had made cyclotronics more of a dark art than a working technology had been resolved, and Lawrence's machine stood ready as the only technique able to meet the need. Something else went along with these exports: "The fascination with hardware and the subordination of the individual to the group that characterized Berkeley by the late 1930s were to spread from the accelerator laboratories to other parts of physics and from the United States to the rest of the world" (p. 351).

Heilbron and Seidel, with Bruce Wheaton, have elsewhere described the story of Lawrence and his laboratory as "a strong interaction between science and society" ("Lawrence Berkeley Laboratory 1931–81" *CERN Courier*, October 1981). Unfortunately, the social context they depict is limited largely to Lawrence's relationships with the powers-that-be. Theirs is a history from the top down, which is certainly an important part of the story. As Raymond Williams observed in another context: "A need which corresponds to the priorities of the real decision-making groups will, obviously, more quickly attract the investment of resources and the official permission, approval or encouragement on which a working technology . . . depends."

But if one is to understand the choices Lawrence made in the 1930s, as compared with those made by Berkeley's other rising physics superstar J. Robert Oppenheimer (the often-made contrast between the two is also made in this book), one must tell some of the history of the 1930s from the bottom up. It was a time of severe economic crisis in the United States, but also a time of great hope. President Roosevelt spoke of "one third of a nation ill-housed, ill-clad, ill-nourished", and of the need to curb the power of the trusts if the country was to be put back on its feet. A wave of protest by the unemployed and of trade-union organization by the employed swept the nation, cresting in California. To understand the California of the time one must evoke not only the Federal Telegraph Company and the Research Corporation, as do the authors, but also the general strike in San Francisco and the efforts to organize migrant farm workers, immortalized in John Steinbeck's *Grapes of Wrath*.

The impact of such events and struggles, which did not leave their own plight unaffected, moved a considerable number of US scientists into political action in broad sympathy with the growing movement to organize labour in factory and field — and laboratory. "Suddenly, prominent scientists were in the forefront of both the antifascist and social reform movements . . . A small though vocal and influential portion of the scientific community became radicalized", reports Peter Kuznick in his recent account of this movement (*Beyond the Laboratory*, University of Chicago Press, 1989). It will not do to say, as do the authors, "Lawrence trusted that the world would muddle through without requiring his attention", while "Oppenheimer did not allow the world to get on without his help" (p. 255). Theirs were political decisions, made in the context of national and international conflicts, the outcome of which were to decide the fate of a generation.

It must be added that the authors' aloof and ironic style, while adding considerably to the amusement of the reader, does not serve well the goal of a deeper understanding of the personalities of Lawrence or the other central figures in the drama. Instead of patronization, for example, one would have wanted more help in understanding what many of Oppenheimer's students — and students of his career — consider his finest hour as a human being and social figure. Lawrence also made his decisions. His biographer reports that: "He warned his people . . . 'If anyone wants to write letters to editors and that sort of thing, he should get out of science and get a job on a paper'" (H. Childs, *An American Genius*, p. 267). The authors' discuss quite frankly Lawrence's anti-semitism, of the conventional midwestern variety typical of his generation, and its repercussions in the lab. They do not mention that: "Though he preferred not to have women in the laboratory at first", presumably because of similar conventional prejudices, "a few were eventually accepted" (Childs). Their own attitude towards women is not unobjectionable: in their text, Lawrence's wife is always "Molly", Lawrence is never "Ernest". Their account of the courtship of lab secretaries (all female) by lab scientists (all male) is reminiscent of anthropological accounts of the exchange of women as a means of male tribal bonding (p. 247).

This long book is not without its *longuers*: much of its length can be attributed to the tendency of the authors to follow their material, however far it leads them from Lawrence and his lab: in some measure, they have written a history of experimental nuclear physics in the 1930s. It would have been helpful if the authors had provided an introductory overview of the entire history of the lab; that they have not done so is surprising since they, together with their former collaborator, Bruce Wheaton, have written two such surveys that carry the story through the seventies (one is cited above; the other, published by the lab, has the same title as this book). Even more surprisingly, neither survey is cited in the extensive bibliography here.

The publisher must be commended for the unusually low price of the book, which certainly justifies its computer-driven look. But something has gone seriously wrong with the index, which is a disaster area. An hour's effort turned up nearly 100 missing page references, and about 40 missing names of people and institutions. A more systematic search of one entry (Szilard) turned up about as many missing references as there are in the index. □

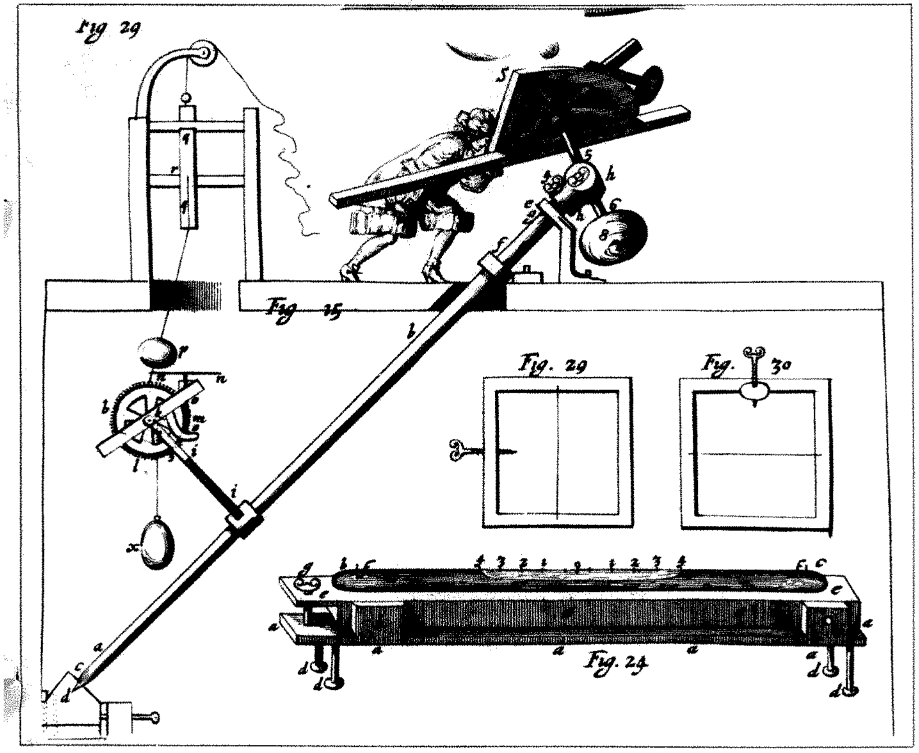
Serious science

Willem D. Hackmann

Robert Hooke: New Studies. Edited by Michael Hunter and Simon Schaffer. *Boydell & Brewer: 1989. Pp. 310. £39.50, $75.*

HOOKE — inventor, architect, surveyor of the city of London and man of science — was one of the most brilliant English scientists in the seventeenth century, eclipsed only by Newton. His mechanical genius was surpassed by no one. Yet in many respects he is still an elusive character, undeservedly better known to the history of science fraternity than to the general public. No portrait of him has survived, although we do have a detailed pen drawing by his biographer Richard Waller: ". . . in person but despicable, being crooked and low in stature, and as he grew older more and more deformed. He was always very pale and lean, and latterly nothing but skin and bone, with a meagre aspect, his eyes grey and full, with a sharp, ingenious look whilst younger. . . He went stooping and very fast, having but a light body to carry, and a great deal of spirits and activity, especially in his youth. . . His temper was melancholy, mistrustful, and jealous, which more increased upon him with his years."



Hooke's equitorial quadrant, with its conical pendulum driving clock. Could the diminutive figure pushing the quadrant be Hooke himself? From Hooke's *Animadversions on the First Part of the Machina Coelestis* (London, 1674).

Hooke became notorious in his lifetime for the many bitter controversies and priority disputes with fellow scientists, notably with Newton, over the theory of colours (1672) and the priority of the law of gravitation (1686), and with Christiaan Huygens over the spring regulator (1674). He also fell out with the Astronomer Royal John Flamsteed, the Danish astronomer Johannes Hevelius, and with a bevy of Royal Society fellows: Sir John Cutler, Henry Oldenburg, Richard Waller, John Woodward and Hans Sloane, to name but the most prominent. Steve Shapin points out in his perceptive chapter in the present volume that some of these episodes might not have resulted from Hooke's cantankerous nature but rather from the ambivalent place he occupied in the *milieu* of seventeenth century science: not quite a 'gentleman scientist' like Robert Boyle, nor a lowly artisan (Hooke styled himself a 'master of technicians'), but someone in a dependent position, an employee who had to survive on patronage. It may not be insignificant that there is no record of him ever having crossed swords with that great patron of science, Robert Boyle, with whom Hooke started his scientific career and who obtained for him the post of Curator of Experiments at the Royal Society. As Shapin concludes, Hooke's pattern of behaviour was not considered exceptional among contemporary tradesmen who had to live from the product of their wits.

This multi-authored volume on different aspects of Hooke yet again illustrates the versatility of the man's genius. What emerges are two fundamental strands of Hooke's work: his enthusiasm for mechanisms (what Richard Waller called "his first and last Mistress"), and his need to underpin his instrumental view of nature by his scientific method. In the opening chapter, Jim Bennett deals with Hooke's instruments for astronomy and navigation and their common concern with angular measurement. The telescope was scarcely regarded as an astronomical instrument before the application of the eyepiece micrometer, championed by Hooke in the early 1660s. A keystone of Hooke's science was his confidence in the potential for instrumental advance as expressed in his controversy with Hevelius, and the development of his novel equitorial quadrant with its conical pendulum driven clock.

A. D. C. Simpson presents an extraordinary detailed analysis of Hooke's concern with practical optics, highlighting the complicated relations between Hooke and the London optical instrument-making trade, and also between Hooke and his colleagues at the Royal Society. Michael Wright has a particular affinity with Hooke because he is a skilled instrument maker. He not only analyses Hooke's attempts to produce a clock for determining longitude at sea, he actually sets about reconstructing the device in brass. David Oldroyd tackles Hooke's enduring interest in geology.

With John Harwood's essay, the book moves from instrumentation to application of the devices, in this case to the strategic use of pictures produced with the microscope to make the new scientific philosophy generally accepted — what Harwood calls the "visual rhetoric" of Hooke's science. John Hendry examines Hooke's scientific method. Hooke not only used instruments to aid the imperfect senses (calling experimentation the "sixth sense" in scientific endeavour), but also as metaphors for describing natural processes. An important aspect highlighted by Hendry is that Hooke's mechanical philosophy cannot be so easily characterized but contains elements of earlier notions of natural magic. Patri Pugliese describes the real contribution Hooke made to Newton's formulation of his inverse-square law of universal gravitation. It is apparent from the ensuing priority dispute that Hooke never appreciated the full magnitude of the step from his ideas to Newton's achievement.

Light relief is supplied by Lucinda Beier's tale of Hooke's determined search for good health, based on his *Diary*. He collected medical recipes (folk remedies and scientific medications) in the same manner as schoolboys collect stamps, reporting on cures such as the use of the blood of a black cat to cure chilblains. Hooke treated his body like a chemical laboratory, testing out all sorts of medicines, such as different types of 'vomits' to purge the system. He was the great medicine-taker of the seventeenth century. Beier teaches us a great deal about contemporary medical practices and attitudes.

What could have been a somewhat dispersive book is ably held together by the introduction. And as its conclusion is a transcript of an hitherto unpublished list of Hooke's possessions at his death discovered in the Public Record Office. Among his dilapidated chattels a chest was found containing £8000 in new and old money, gold and silver. Richard Waller was moved to "a melancholy Reflexion" of how much good this could have done "for the promoting of Learning" if Hooke had only left a will. Instead the money passed on to an illiterate distant relative. Even so, Hooke emerges from this book as the figure that turned the Royal Society into a serious scientific institution. ☐

Imitating nature — the fruit of the goosegrass (left) hooked onto a woollen sweater provides the model for Velcro, a tough, manufactured nylon 'hook and loop' fastener. The top right micrograph depicts a goosegrass hook with a single snared wool fibre. Bottom right, the synthetic equivalent, a Velcro hook woven into a fine, flexible nylon base material. Micrographs reproduced from the new edition of *Under the Microscope* by J. Burgess, M. Marten and R. Taylor. Cambridge University Press, £12.95, $19.95.

Tribal tribute

Len Goodwin

Laughing Death. The Untold Story of Kuru. By Vincent Zigas. *Humana: 1990. Pp. 315. $24.95, £29.50.*

VINCENT Zigas, who died two years ago, was born in Germany. He had served as a medical officer in Hitler's army and in 1950, in search of a new life, took Australian citizenship and was posted as a bush doctor to the highlands of New Guinea. He fell deeply in love with the island — its steep mountains, hot, wet forests and, above all, its stone-age people — this is his second autobiographical book about his "green dwelling". Conditions when he arrived were primitive; disease and death were all around. Zigas struggled to understand the native languages, prejudices, taboos and intricate ways of thought and behaviour so that he could improve health and hygiene.

When he went to work in the Okapa district among the Fore people, a distinctive tribe with its own traditions and cannibalistic rituals, Zigas became intrigued with kuru, a neurological disorder attributed to sorcery. Women were more commonly affected than men; the condition struck suddenly, advanced inexorably, causing tremor, ataxia and inane laughter, and was always fatal in about a year. It was not impossible that the strong local belief in sorcery could have caused hysterical behaviour patterns of this kind. As Zigas says, "the native lives in a world in which there is normally very little difference between reality and unreality . . . belief in magic and the supernatural provides ideal soil for the growth of acute suggestibility". But he was not satisfied; he suspected an infectious cause and pleaded with the Australian authorities to back up his investigations. Because of his special relationship with the people, who liked and trusted him, he was able to collect patients for visiting clinicians to examine and blood, urine and post mortem samples for Macfarlane Burnet's scientists in Melbourne.

Nothing much came of Zigas's studies until a visiting virologist from the United States, Carleton Gajdusek, also became fascinated by kuru, avidly collecting case-histories, data and samples for analysis. According to Zigas, who had a big chip on his shoulder about being a 'naturalized' Australian and bossed by those who had never worked in the field and who despised the natives, Gajdusek's activity was resented by the Australian medical hierarchy. The establishment tried to bar Gadjusek and, in the mistaken belief that kuru was a genetic disease, to isolate the Fore people and prevent their movement to other parts of the country. Fortunately, this plan did not succeed.

The suspicion that kuru might be caused by an infectious agent was reinforced by the discovery that scrapie, a disease with similar neurological effects and pathology affecting sheep, could be transmitted to other animals and was caused by a 'slow' virus. Eventually, Gajdusek succeeded in transmitting kuru from human brains to chimpanzees and was awarded a Nobel prize. Transmission in the field was shown to be associated with cannibalism, the women of the tribe preparing the brains of the dead for the ritual feast probably becoming infected through abrasions of the skin.

With the spread of education and the end of cannibalism, kuru has now almost disappeared. But it was the first of the human encephalopathies shown to be transmissible, and this opened the field for the investigation of a whole series of unconventional, very resistant, non-immunogenic viruses and their relation to spongy degenerative diseases of the central nervous system. The lesson taught by kuru, human immunodeficiency virus and, most recently, bovine spongiform encephalopathy seems to be that we transgress the old rules of behaviour at our peril.

This is a not a book for the squeamish — bloody stumps alive with maggots, dying infants, rotting corpses, faeces, pus and every kind of secretion and emission are enthusiastically described. Zigas also tells the story of how, on one occasion, he narrowly missed having a kuru brain cooked and served for his own dinner.

Gajdusek could not have succeeded without him. In an affectionate tribute in the foreward to the book, Gajdusek likens Zigas to a Don Quixote or Danny Kaye in appearance, speech, movements and actions. He disagrees with many of Zigas's 'facts' and judgements, and his "uncertain verdict" on the book is that "he has written the most remarkable work in existence of abstract expressionistic ironical parody, his own style of biography" — and that sounds fair. ☐

VCH Book of the Week:

Jork, H. et al.

Thin-Layer Chromatography

Reagents and Detection Methods

Volume 1a: Physical and Chemical Detection Methods: Fundamentals, Reagents I

1989. XV, 464 pages with 183 figures, 16 in color, and 34 tables. Hardcover.
DM 148.00. ISBN 3-527-27834-6

This publication, which will be continued in later volumes, is far more than a collection of reagents - it is a laboratory handbook for the experimentalist. The first part of this volume describes general methods, including prechromatographic derivatization, whilst the second part gives numerous applications listed according to the detection reagent employed.
The authors describe the selected methods in detail and critically evaluate each reagent. Each reaction procedure is concluded with a tested example. Detection limits and measurement conditions are also given.

Late Cenozoic uplift of mountain ranges and global climate change: chicken or egg?

Peter Molnar & Philip England

The high altitudes of most mountain ranges have commonly been ascribed to late Cenozoic uplift, without reference to when crustal thickening and other tectonic processes occurred. Deep incision and recent denudation of these mountain ranges, abundant late Cenozoic coarse sediment near them, and palaeobotanical evidence for warmer climates, where high mountain climates today are relatively cold, have traditionally been interpreted as evidence for recent uplift. An alternative cause of these phenomena is late Cenozoic global climate change: towards lower temperatures, increased alpine glaciation, a stormier climate, and perturbations to humidity, vegetative cover and precipitation.

NOT long after continental glaciation had been recognized, Dana[1] linked it to a late Cenozoic rise of mountain ranges. Over the next 100 years, several eminent Earth scientists[2-7] supported and developed this idea, but in all cases the main logical link remained the temporal correlation of mountain building with the onset of glaciation. Then, when geologists discovered more than one Pleistocene glaciation, the significance of this correlation temporarily lost favour.

Now, with Pleistocene glaciations recognized as a consequence of variations in the Earth's orbit[8] superimposed on a long-term global cooling throughout the Cenozoic era, attention has again been directed to the association of this cooling with regional elevation changes[9,10]. Uplift of large mid-latitude terrains could effect a global cooling by three different physical mechanisms. First, increased elevations at temperate latitudes could extend the duration of winter, and with increased durations of snow cover, the albedo should increase[11]. Second, the increase in elevation of large regions should profoundly affect the circulation of the atmosphere, and experiments with general circulation models suggest that the presence of high terrains in Central Asia and western North America would lead to lower global temperatures than if these areas were low[12]. These experiments also match a number of observed regional climate differences that are not obtained in such experiments on landscapes with little or no high terrain[13]. Finally, chemical weathering, enhanced by the increased exposure of minerals eroded rapidly from cold high altitudes and transported to warmer, moister low elevations, would absorb more carbon dioxide from the atmosphere, thus decreasing the natural 'greenhouse effect'[14]. In view of the simple logic of these physical mechanisms, and the impressive correlations of calculated with existing regional climate differences[13], the weak link in the argument relating climate change to late Cenozoic mountain building becomes the inference that mountain ranges and high plateaux rose in late Cenozoic time.

In what follows, we argue that most of the evidence used to infer late Cenozoic uplift could, in large part, be a consequence of the very climate changes that this supposed uplift is thought to have caused. Undoubtedly, some regions are higher today than they were 2 or 10 Myr ago, but many may simply appear to be higher because the geological effects of late Cenozoic climate change could cause the same changes in the landscape and fossil record as regional uplift would.

The Cenozoic climate record

Both palaeobotanical data[15] and oxygen isotopes[16-18] indicate

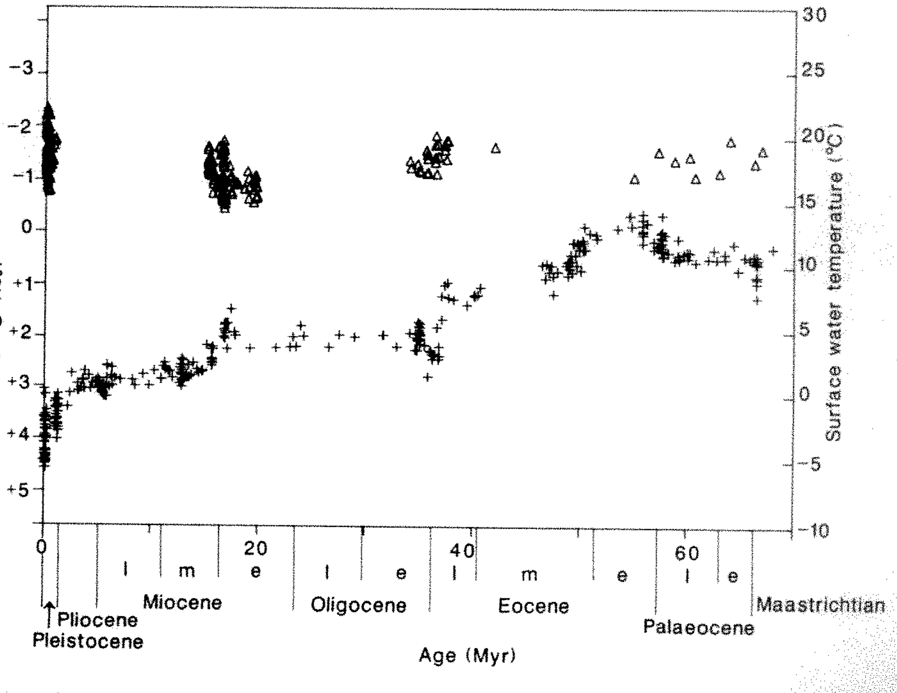

FIG. 1 Oxygen isotope records (and inferred temperatures) for the past 70 Myr from low-latitude surface waters of the Pacific (△) and from ocean deep waters as observed in the South Atlantic (+). Because ocean deep waters are formed at high latitude, the lower curve can be taken as representing the isotope composition of high-latitude surface water. The temperature scale is valid only in the absence of an Antarctic ice sheet—roughly up to mid-Miocene time. Including a correction for the effect of the ice sheet would raise more recent temperatures by ~3 °C. (Figure courtesy of N. J. Shackleton, modified after ref. 17.)

a monotonic, but not steady, cooling of the Earth over the past 50 Myr. Abrupt decreases in temperature occurred near the Eocene/Oligocene boundary[15-21] (~36 Myr ago), at ~15 Myr in the Miocene epoch[16,17,22], and at ~2.5 Myr near the end of the Pliocene epoch[16-18], when continental glaciation in the Northern Hemisphere began[23]. Moreover, the decrease in temperature has been much greater at high than at low latitudes[15,18,24]. For example, oxygen isotopes from planktonic foraminifera deposited at sub-Antarctic latitudes indicate a decrease in surface water temperatures of ~12 °C since late Eocene time[16,17], but those from equatorial latitudes indicate hardly any change in such temperatures[18,24] (see also Fig. 1). Similarly, a comparison of late Quaternary and present-day elevation ranges of plants growing in the equatorial Andes indicates a temperature difference of ~4.5 °C (ref. 25), but oxygen isotopes from cores in Antarctic ice of the same age imply temperatures 11 °C lower than today[26]. The resulting increase in latitudinal temperature gradient is important because it promotes an increased transport of water vapour and latent heat from low to high latitudes[27], and therefore a stormier climate.

Definitions of uplift

The geological literature is much confused by an inconsistent definition of the word uplift[28]. Uplift is a vector opposite to the gravity vector, and a meaningful definition must specify both a reference frame and an object that moves. The most useful reference frames are the geoid (sea level corrected for eustatic changes) and the Earth's surface; the objects that move are either particular rocks or, again, the Earth's surface. In the physical processes linking elevation and climate change[11-13], what matters most is the uplift of the Earth's surface relative to sea level, which is the change in mean elevation. This cannot be measured directly and must be inferred indirectly (see below).

The uplift of rocks relative to the local Earth surface, as measured using geochronology and petrological geobarometers and geothermometers, can be called 'exhumation', and is equal to the thickness of rock removed from the Earth's surface[28,29]. By isostasy (Archimedes' principle applied to light crust overlying heavier mantle), the removal of a layer of crust of thickness ΔT and density ρ_c, compensated by a crustal root in a mantle of density ρ_m, results in a lowering of the surface of $\Delta T\ (\rho_m - \rho_c)/\rho_m \approx \Delta T/6$ (Fig. 2*a*). Thus, the isostatic response to rapid erosion of a region of gentle relief and mean elevation h could transform it into one with peaks at heights of $2h$ (or higher), with valleys near sea level, but with a *lower* mean elevation of only $0.83h$ (Fig. 2*b*).

The uplift of rocks relative to sea level is the sum of the uplift of the Earth's surface and exhumation[28]. As an example, the heights of marine terraces above sea level (corrected for eustatic

FIG. 2 Simplified crustal sections showing the effects of erosion and crustal thickening on mean elevation, depth of the Moho (the crust/mantle boundary) and uplift of rock. *a*, Imagine a mountain range (left) of mean elevation h, depth to the Moho H and crustal thickness $T=H+h$, and allow a thickness of crust ΔT to be eroded. By isostasy, the mean elevation should decrease by $\Delta h \approx \Delta T/6$, and the underlying rock, including the Moho, should rise by $5\Delta T/6$ (centre). Hence, an exhumation of ΔT yields uplift of rock of $5\Delta T/6$, but a lowering of mean elevation of $\Delta T/6$. Only if, simultaneously, tectonically caused crustal thickening at depth replaces the thickness of crust, ΔT, lost by erosion, will the mean elevation and the depth to the Moho remain constant (right). This is what seems to be happening in the Southern Alps of New Zealand[50] (see text). *b*, Similarly, if a gentle highland of mean elevation h (left) were deeply incised by rivers that eroded valleys nearly to sea level (right), the mean elevation should drop slightly to about $5h/6$, the remaining rock and Moho would rise by an amount equal to h, and the highest peaks would be much higher than before. In this way, a climatically induced increase in erosion rate can cause exhumation of rocks, and hence the appearance of uplift, with no increase (in fact, with a decrease) in mean elevation.

changes) provide a direct measure of the uplift of the rocks concerned. But the heights of such terraces would equal the change in mean elevation of the terrain only if no material had been removed by erosion. The uplift of such terraces could be caused entirely by tectonic processes, if there were no erosion, or entirely by isostasy, if the uplift of these rocks were merely the isostatic response of the terrain to the removal of material by erosion.

Evidence used to infer recent uplift

We contend that many inferences of recent uplift of mountain ranges are based not on measures of uplift of the Earth's surface, but on estimates either of uplift of rocks or of exhumation[28]. Furthermore, some of the phenomena used as indicators of uplift could in fact be caused by climate change. An abrupt change in climate, as seems to have occurred at ~15 Myr[22], and as clearly occurred at ~2.5 Myr[23], is likely to affect the rate at which the landscape evolves. An increase in alpine glaciation will incise and denude high terrains, and changes in precipitation are likely to affect erosion rates. We suggest that a change towards a cooler and stormier climate could be responsible for the geomorphological evidence ('youthful landscapes') often used to infer recent uplift. Similarly, increased denudation and exhumation should yield an increase in the rate of coarse terrigenous sedimentation, a phenomenon also often attributed to uplift. Finally, global cooling has contributed to the change in mountain flora from warmth-loving species to those characteristic of cooler environments—palaeobotanical evidence that is commonly taken to indicate recent uplift of the fossil material relative to sea level.

Geomorphology. One of the observations commonly used to infer recent uplift is the sharp incision by streams and rivers into gentle surfaces mantled by late Cenozoic sediment. It is a basic tenet of geomorphology that the uplift of a surface with respect to the base level of the streams provides the streams with increased potential energy and steeper gradients, leading to rapid incision of the surface.

Such observations comprise the primary evidence for de Sitter's[30] postulation of 2,000 m of Pliocene uplift of the Pyrenees and Alps, and 1,000 m for the High Atlas mountains. From incised erosion surfaces at 1,000–2,000 m on the north flank of the Pyrenees and an extrapolation to 3,000 m near the crest of the range, de Sitter inferred 2,000 m of uplift since the beginning of the Pliocene epoch. Similarly, Trümpy[31] reported that the Pliocene Alps were 'not more than a hilly tract', whereas now deep valleys near sea level separate ridges with crests rising to 4,000 m. Because the present mean elevation of the Alps is only ~2,000 m[32], however, de Sitter's[30] inferred uplift of 2,000 m could simply be the isostatic response to the removal of material by the incision of the deep valleys (see Fig. 2*b*). It is easy to imagine that global cooling enabled alpine glaciers to grow and to excavate deep valleys. We do not suggest that the Alps and Pyrenees underwent no erosion for tens of millions of years before 2.5 Myr, but rather that a change in the processes of erosion and an increased erosion rate reshaped the gentle early Pliocene landscape into jagged relief.

Like those in the Alps and Pyrenees, the major structures of the Rocky Mountains of Colorado, Wyoming and Utah formed in late Cretaceous and early Cenozoic time. Partly because a high erosion surface has been deeply dissected in late Cenozoic time, much of the present elevation of the Rockies is nearly unanimously assigned to the Pliocene and/or Pleistocene epochs[33–36]. But, as "glacial erosion was the chief cause of the destruction of the Eocene surface in the higher parts of the mountains" (ref. 35, p. 244), here too, climate change should be considered as a contributor to accelerated erosion rates, and the appearance of recent uplift.

Sedimentation. Widespread rapid denudation manifests itself not only by the exhumation of rock, but also by an increased rate of deposition of sediment, near or far from the exhumed terrain. Thick deposits of late Cenozoic conglomerate surround most steep mountain ranges, and the large cobbles that comprise conglomerate imply transport along steep slopes. Thus, "tectonic activity is commonly held responsible for abrupt coarsening of alluvial fan sequences"[37]. Potter[38] used this argument to infer late Tertiary uplift of the southern Appalachians. Another of the arguments for recent uplift of the Rocky Mountains derives from the presence of thick late Cenozoic conglomerate near them[33,34,39]. Uplift of one block with respect to another can cause steep gradients, but, as Blackstone[33] noted for one basin in the Rockies, climate change also can affect the potential for streams to transport large cobbles. As Frostick and Reid[37] pointed out, infrequent but large storms can produce the abrupt coarsening of fanglomerate stratigraphy that is commonly attributed to tectonic processes.

Accelerated denudation is also revealed by sediment accumulation far from mountain ranges. Accumulation rates of pelagic sediment in the Atlantic, Indian and Pacific oceans in late Cenozoic time exceeded those for the rest of that era[40], with a four- to fivefold increase[41] in the rate of terrigenous deposition since 5 Myr. Like Donnelly[42], we suspect that the rapid increase in sediment accumulation throughout the world is a consequence of climate change.

The deposition rate since 2 Myr in the Gulf of Mexico, and in particular in the Mississippi delta, has been roughly four times that for the previous 60 Myr (see Fig. 3), and Hay *et al.*[43] argued that most of this material has come from the Rocky Mountains. Using constant quantitative relations among elevation differences, rates of sediment transport, base level to erosion, and an assumed history of eustatic sea-level change, they calculated a large late Cenozoic uplift of the Rocky Mountains from this thick Quaternary sediment. Because sediment transport rates also depend on climate[44–46], however, a different relationship between sediment transport and elevation for late Cenozoic and earlier times would yield a different, perhaps negligible, inferred Quaternary uplift of the Rockies.

The rapid denudation of the Southern Alps of New Zealand, where a wealth of observations indicate rapid uplift of rock with respect to sea level[47–49], illustrates the relationship of uplift of rock to both denudation and tectonics. Adams[50] showed that the regional erosion rate, determined both from suspended sediment in streams and from sediment accumulations around the island, is comparable to the rate of uplift of rock. Thus, the isostatic response to the removal of material must be a major cause of the present uplift of the marine terraces. To see this, remember that for each 1 km of material removed from the range, the isostatic response is a lowering of the mean elevation by only ~0.17 km (Fig. 2). Thus, although in the steady state that Adams[50] deduced, tectonic processes seem to maintain a supply of rock to be eroded (by thickening the crust), nevertheless, if tectonic processes stopped, five-sixths of the uplift of rock would still occur. Oblique convergence between the Pacific and Australian plates[51,52] has occurred in the region of the Southern Alps since 10–15 Myr[50], but virtually all of the sediment in the basins surrounding the Southern Alps seems to be younger than 2.5 ± 0.5 Myr. Thus, the recent increase in the rates of sedimentation and erosion correlates well with the onset of 'Pleistocene' glaciation, at least as dated in the Northern Hemisphere[23], but not with any resolvable change in plate motion[51,52].

Palaeobotany. The main cause of the enormous variation in vegetation over the Earth is the variation in climate. Thus, to use palaeobotany as a palaeobarometer, one must first use it as an indicator of palaeoclimate and then relate that climate to an inference of what the climate would have been in the same region at sea level.

One palaeobotanical approach used to infer palaeoclimates exploits qualitative relationships between assemblages of different taxa and the climates that characterize their present environments[53]. One assigns the fossil plants 'nearest living relatives', and then finds a present-day environment that includes

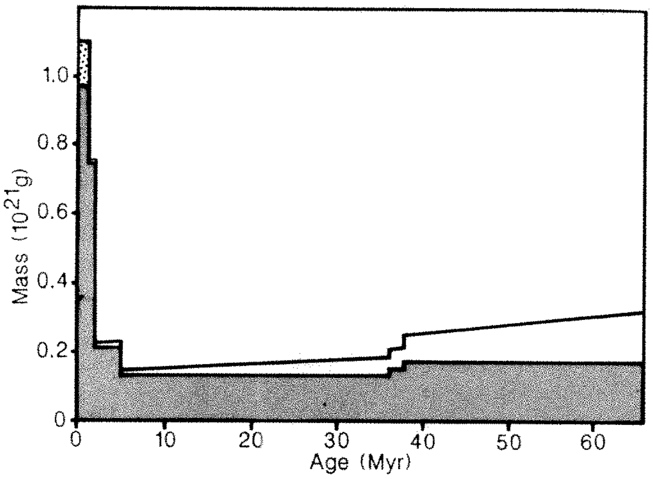

FIG. 3 Mass of Cenozoic sediment in the northwestern Gulf of Mexico and its drainage basin, between the Rocky Mountains and the Appalachians, as a function of the age of the sediment (from ref. 43). The blackened area shows existing sediment, minus an estimate by Hay *et al.* of the sediment transported by the Laurentide ice sheets from the Canadian shield in the past 1-2 Myr and deposited in this drainage basin. The line above shows their estimate of the sediment that was deposited and subsequently removed. Note that the huge increase in sedimentation at ~2 Myr correlates with the abrupt onset of widespread glaciation in the Northern Hemisphere[23].

as many of these relatives as possible. From the characteristics of that environment, one infers a likely palaeoclimate of the region[53]. The assignment of a nearest living relative is likely to be easiest for the most recent geological past; for Miocene and older times, a substantial fraction of the fossil species are extinct, and the conditions in which many of them lived must have been different from those of their descendants. For example, Axelrod[54] found that most of the nearest living relatives of fossil taxa from the Eocene Copper River formation in northeastern Nevada grow in either of two types of forest: coastal redwood forests, where elevations range from sea level to ~150 m, and fir-hemlock forests in the Sierra Nevada, at elevations of 1,400-2,400 m. Clearly, assigning a palaeo-elevation (or palaeoclimate) to such a fossil assemblage from present-day equivalents requires an element of subjectivity that makes the method qualitative at best[55].

Moreover, sometimes the taxonomic classification is based on parts of a plant, such as pollen, that can be relatively insensitive to climate change. Fossil pollen may have fallen from trees whose leaves and wood have since evolved to be adapted to a different climate, while the pollen remains similar. As an extreme analogy, imagine finding late Quaternary tusks in the Siberian Arctic, matching them to the nearest living relative, the elephant, and concluding that because elephants now live in hot, dry savannas at low latitudes, the present North Pole also lay at tropical latitudes in the late Quaternary era. Tusks are not adaptations to climate.

A second palaeobotanical approach to palaeoclimate ignores, insofar as is possible, the taxonomy of the fossil plants and simply uses what is known of how plants adapt to different climates. Using trees from eastern Asia, Wolfe[56] showed that the percentage of species having leaves with smooth, continuous margins ('whole margins') varies linearly with mean annual temperature, with a scatter of only 2 °C. The application of physiognomic characteristics to palaeoclimates is not without limitations[56], but climate changes inferred from the physiognomy of fossil plants have been corroborated. From leaf shapes, Wolfe[15,19,20] deduced an abrupt drop in temperature of several degrees in only a couple of million years near the Eocene/Oligocene boundary. Oxygen isotopes from the sub-Antarctic region near New Zealand later corroborated this rapid decrease in both surface and bottom water temperatures[16,21]. Using nearest living relatives, however, Axelrod and Bailey[57] inferred only a gradual change.

Virtually all attempts to use palaeobotany to infer palaeo-elevations have relied on taxonomy, not physiognomy. Moreover, many studies, such as those reporting recent uplift of the Tibetan plateau or the Himalayas[58-61], have ignored global climate change. Given that most of the Earth cooled during the late Cenozoic era[15-18], it is not surprising that palaeobotanical observations make it seem that mountain ranges have risen recently. For an average lapse rate of $\sim 6\,^{\circ}\mathrm{C\,km^{-1}}$, a secular change in temperature of 6-9 °C since 5-15 Myr[16-18] could yield an erroneous inference of 1,000-1,500 m of uplift. Moreover, because environmental lapse rates tend to be lower than free-air lapse rates[62], such a change in mean annual temperature could lead to a larger error in inferred uplift. Thus, although both the Himalayas and Tibet rose in Cenozoic time, the palaeoclimatic inferences of an accelerating rise throughout Cenozoic time[58-61] (see Fig. 4) are likely to be exaggerated, if not simply false[28].

The Rocky Mountains provide another example of exaggerated, palaeobotanically determined, late Cenozoic uplift. MacGinitie[63] noted that many of the species from the early Oligocene Florissant flora in central Colorado could not be matched with present-day equivalents from any single, well defined forest; nevertheless, he inferred a relatively warm mean annual temperature of 18 °C and a palaeo-elevation of less than 915 m. The evidence for warm climates where early Eocene (Laramide) deformation had created mountain ranges is a common argument for low palaeo-elevations[39,64,65], and the palaeo-elevation of Florissant has provided a base level for estimates of subsequent uplift of the whole of the Rockies and the Great Plains[65]. Recall, however, that the late Eocene/early Oligocene climate was very warm—warmer than it has been since then[15-18].

Using the physiognomy of the fossil leaves of the Florissant assemblage, Meyer[66] inferred a mean annual temperature of 14 °C, not greatly different from MacGinitie's 18 °C. By comparing this with the likely warm early Oligocene sea-level temperature at the same latitude, however, and using an appropriate lapse rate and a 200-m difference between early Oligocene and present sea level, Meyer[66] inferred a palaeo-elevation of 2,450 m. Even if a smaller sea-level difference were used, this would be indistinguishable from the present elevation of 2,600 m. He also inferred a high palaeo-elevation of 2,800-3,500 m for the nearby Marshall Pass flora of roughly the same age, presently at 2,835-3,080 m. Moreover, from the physiognomic characteristics of the late Oligocene Creede flora, at 2,680 m in central Colorado, Wolfe and Schorn[67] inferred a mean annual temperature of 0-2.5 °C, which is virtually identical to the present mean annual temperature of 1.9 °C. Ironically, because Wolfe and Schorn[67] were prejudiced by the prevailing opinion that the Rockies rose only in late Cenozoic time, they suggested that the Creede flora were deposited in a basin where cold air could be trapped. Thus, Meyer's[66] and Wolfe and Schorn's[67] analyses, based on physiognomic characteristics of fossil plants and on differences in present and past climates, show that differences between past and present taxa should not be taken as evidence of low elevations in the western United States in mid-Cenozoic time and of a subsequent recent increase in the mean elevation of the Rockies.

Climate change and the appearance of uplift

The arguments above are intended to show that most estimates of late Cenozoic uplift of mountain ranges are exaggerated, at least if changes in mean elevation define uplift, and to suggest that much of the evidence used to infer recent uplift is a consequence of climate change. Most palaeobotanical inferences of recent uplift of the Earth's surface ignore global cooling, which biases these estimates upward. Inferences of changes in mean elevation from elevated geomorphic surfaces, increased denudation or increased sedimentation overlook the parts played by erosion, which depends on climate[44-46], and by isostatic rebound. Isostatic compensation of material removed by erosion will elevate the remaining terrain, but the uplift of ridges and peaks with respect to sea level does not necessarily signify an increase in mean elevation. Our attribution of the rapid erosion of mountain ranges in late Cenozoic time to climate change must remain a hypothesis, given that climate change can be very different in different places[13], that different types of local climate change can increase erosion rates[44-46], and that it is difficult to distinguish a local climate change due to global processes from one due to local uplift. Nevertheless, the same difficulties face the geologist trying to show that the recent rapid incision of a major mountain range is due to uplift, instead of global climate change.

The correlations of global climate change with the phenomena used to infer uplift offer some support for the idea that climate change is responsible for these phenomena. The physiognomy of Oligocene fossil plants from the Rocky Mountains[63,66,67] is consistent with the climates that would be expected at present elevations, if known global climate changes[15-18] are allowed for, but with lower elevations if that global cooling is ignored. Moreover, much of the deep incision of the erosion surface across the Rocky Mountains was due to glaciation[35]. In fact, most major mountain ranges thought to have risen in late Cenozoic time have been glaciated, and glaciation increased greatly as the Earth became cooler. The onset of rapid sedimentation in New Zealand at ~2.5 Myr[50], due to rapid erosion of the Southern Alps, correlates with the onset of late Cenozoic cooling and glaciation[23], but not with any obvious change in tectonics[51,52]. Finally, late Cenozoic uplift has been inferred for mountain ranges throughout the world, yet globally synchronous changes in plate motions, if they have occurred, have been small. Climate change, on the other hand, has been a global phenomenon.

Although the physical mechanisms by which global climate change might affect erosion rates could be different in different regions, several plausible processes are likely to have enhanced erosion. At relatively high altitudes or high latitudes, alpine glaciation is likely to be the dominant process of erosion, and global cooling surely enhanced glaciation. In the absence of glaciation, the principal "agents of erosion and transportation are the impact of raindrops and the surface flow of water"[46], but variations in precipitation can affect erosion in such extreme ways that one cannot assume that more precipitation would lead to more erosion, or vice versa. In some climates, increased precipitation can increase erosion, but in others, a decrease in precipitation can increase erosion, by reducing the amount of protective vegetation[68]. Whether global cooling led to increased or decreased precipitation is difficult to decide (see below) and likely to vary regionally.

The atmosphere is a thermal engine, which absorbs the Sun's energy in the tropics and transports it upwards and polewards as both sensible heat and latent heat in water vapour. Precipitation in middle latitudes is strongly affected by the ability of the atmosphere to transport humid air from the tropics to cooler higher latitudes. This transport is accomplished primarily by large-scale eddies generated by baroclinic instability[27], the same instability that makes the climate stormy. Two aspects of the temperature field affect the rate of transport: the strong temperature dependence of the saturated mixing ratio of vapour and dry air, and the latitudinal temperature gradient. The mixing ratio is proportional to $\exp(-L/RT) = \exp(-5{,}400/T)$, where L is the latent heat of vaporization, R is the dry-air gas constant, and T is temperature in degrees Kelvin[27]. The strong dependence of the mixing ratio on temperature makes cooler air much drier than warm air, implying that global cooling would lead to drier climates and less precipitation. The rate of transport, however, is also proportional to the square of the latitudinal temperature gradient. Thus, the inferred change from ~0.25 to 0.5 K per degree of latitude since early Cenozoic time[15] would yield a fourfold increase in latitudinal transport of moisture, but a decrease in mid-latitude temperature of 10 K would yield only a 1.8-fold decrease in water vapour transported. This kind of calculation, which ignores the reduced evaporation at middle latitudes at lower temperatures, is too imprecise to allow a definitive statement about changes in precipitation during Cenozoic time, but it emphasizes that global cooling would not necessarily reduce precipitation. More importantly, the increased latitudinal temperature gradient should have enhanced baroclinic instability, making the climate stormier. Annual erosion rates in many areas are dominated by a few storms[44,46]; thus, even if global cooling did lead to a drying, as some general circulation model runs suggest[69], the increased storminess could have increased net erosion.

Climate change and uplift: chicken and egg?

The temporal correlation of late Cenozoic glaciation with phenomena commonly ascribed to recent uplift is inescapable, but assigning the ultimate cause of late Cenozoic climate change to late Cenozoic uplift arising from tectonic processes is a hypothesis that we reject. Instead, we have suggested here that

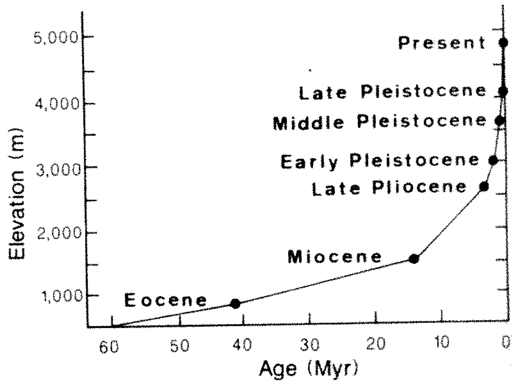

FIG. 4 Inferred history of uplift of the Tibetan Plateau and the Himalayas, based on palaeobotanical data largely from the north slope of the Himalayas. (Redrawn from ref. 60.) Fossil species whose nearest living relatives grow at relatively low elevations and in relatively warm climates were used to infer lower past elevations, but no account was taken of global cooling, as illustrated in Fig. 1. We show this as an example of inferred uplift, but we doubt that it is precise, or that it applies to all of the Tibetan plateau.

the phenomena commonly used to infer recent uplift are a consequence of climate change.

This is not to dismiss entirely the processes linking elevation and climate described by Birchfield, Kutzbach, Raymo, Ruddiman and Weertman[9-14]; indeed, there is evidence for their operation in a longer-term correlation (if only crude) of climate change with the growth of high terrain in the past 50 Myr[10]. There was no Tibetan plateau in late Cretaceous time, when marine limestones were being deposited in the region[70]. Moreover, because the present tectonic activity in Asia seems to be due to the collision of India withEurasia in Cenozoic time, the high mean elevation of much of the rest of eastern Asia was also probably acquired during Cenozoic time. Thus, the gradual cooling over the past 50 Myr might be the consequence of the tectonic processes that built Tibet, the Himalayas and other high terrains in Asia.

It follows that changes in mean elevation, climate change and the phenomena commonly used to infer uplift are coupled to one another. Although the physical mechanisms linking climate change to uplift should apply most strongly to regions where mean elevation has increased, they could also operate where crests of ranges have risen in response to erosion and isostatic rebound. This raises the possibility that climate change, weathering, erosion and isostatic rebound might interact in a system of positive feedback. Suppose increased weathering and erosion could enhance a negative 'greenhouse effect'[14]; then, if climate change accelerated erosion and weathering, the associated withdrawal of carbon dioxide from the atmosphere might cause further global cooling. Increased rates of erosion and isostatic rebound would alter the distribution of elevations by making the crests of ranges higher than before. The prolonged duration of winter and snow cover in such higher areas might lead to further reductions in temperature[11]. In addition, mountain ranges with high crests and deep valleys will perturb atmospheric circulation more strongly than those with the same mean elevation but lower crests. Thus, if the rise of crests of mountain ranges were to perturb the climate in such a way as to enhance erosion, isostatic rebound would cause a further rise, and further perturbations to the climate. By such feedback mechanisms, the gradual regional uplift of the Earth's surface in Asia, due to Cenozoic tectonics, might have led to an accelerating climate change and the illusion of accelerated uplift of mountain ranges throughout the world. □

The protein encoded by the *Arabidopsis* homeotic gene *agamous* resembles transcription factors

Mutations in the homeotic gene *agamous* of the plant *Arabidopsis* cause the transformation of the floral sex organs. Cloning and sequence analysis of *agamous* suggest that it encodes a protein with a high degree of sequence similarity to the DNA-binding region of transcription factors from yeast and humans and to the product of a homeotic gene from *Antirrhinum*. The *agamous* gene therefore probably encodes a transcription factor that regulates genes determining stamen and carpel development in wild-type flowers.

ARABIDOPSIS THALIANA is widely used for molecular and genetic studies of many developmental processes in plants[1,2]. We have focused on the molecular basis of pattern formation in developing *Arabidopsis* flowers. Flower development remains one of the most complex processes unique to plants, and little is known about the molecular mechanisms involved. Flowers develop from a few undifferentiated cells into a structure that has several types of organs occupying precisely defined positions. *Arabidopsis* has typical mustard flowers (Fig. 1*a*) consisting of four concentric whorls of organs[3]. The first or outermost whorl consists of four green sepals. Interior to and alternating with the sepals are four white petals which make up the second whorl. The third whorl consists of six stamens, four long and two short, each of which has a filament capped by a pollen-bearing anther. The fourth and innermost whorl consists of two fused carpels capped by a short style and stigmatic papillae.

Many mutations affecting floral morphogenesis have been identified in *Arabidopsis*. Mutations in at least four genes result in homeotic transformations of floral organs[1,3-7]. In general, these homeotic mutations affect the development of adjacent whorls of floral organs. For example, the *ap2-1* mutation results in the conversion of the sepals into leaf-like organs, and in the conversion of petals into stamen-like organs[3]. Mutations in the *AP3* (*ap3-1*) or *PI*(*pi-2*) genes result in the conversion of petals into sepals and stamens into carpels. Mutations in the *agamous* (*AG*) gene result in the overall phenotype of a flower within a flower and the absence of stamens and carpels. The six stamens have been replaced in *ag* mutant flowers by six petals, and the carpels have been replaced by a new flower. Thus, *ag* flowers consist of ten petals (four normal and six in the place where stamens are normally found) inside of the four sepals, and inside the petals are again four sepals and ten petals (Fig. 1*c*). This pattern repeats itself and the resulting flower can consist of more than 70 organs. Other species of plants with similar double flower phenotypes were recognized as long ago as 2,000 years[8]. The first published report of *Arabidopsis* flowers with an *ag* mutant phenotype was more than a century ago[9], and another *Arabidopsis* mutant having similar flowers has been described by Conrad[10]. The extensively characterized[3] mutant allele, *ag-1*, was isolated after ethylmethane sulphonate (EMS) mutagenesis and was first described by Koornneef *et al.*[11]. The *AG* locus has been mapped to chromosome 4 (ref. 11).

Here we describe the molecular cloning and characterization of the *AG* gene, which was facilitated by a T-DNA insertion mutation[12]. The deduced AG protein product is similar to transcription factors from humans (SRF) and yeast (MCM1, ARG80), and to the product, DEF A, of a recently isolated homeotic gene from the snapdragon *Antirrhinum majus*.

Insertion mutant of *agamous*

Recently, a method has been developed to tag genes by insertion of the T-DNA from *Agrobacterium tumefaciens*[13]. One of the

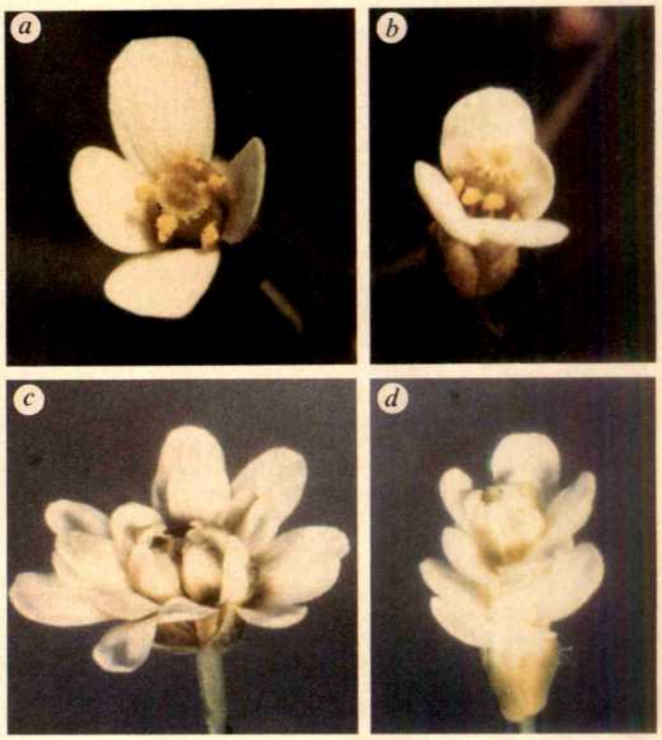

FIG. 1 Photographs of *Arabidopsis* flowers. *a*, Wild-type; *b*, *ag-2* plants transformed with pCIT540; *c*, *ag-1*; *d*, *ag-2*. Complementation of the *ag-2* mutation was tested by introducing the cosmid pCIT540 into the *Agrobacterium* strain ASE (ref. 26). This strain was used to infect leaf pieces of homozygous *ag-2* mutant plants by standard methods[27]. A regenerated plant that displayed wild-type flower morphology is shown here.

mutants isolated by this approach (Fig. 1*d*) displays a phenotype that closely resembles that of *ag-1* mutant plants (Fig. 1*c*). Like *ag-1*, this insertional mutant lacks stamens and carpels and has the overall phenotype of a flower within a flower. The only noticeable difference between the insertional mutant and *ag-1* mutant plants is that the pedicels of inner flowers in the former are elongated, resulting in a greater separation of internal flowers. The elongated pedicel is not due to the insertional mutation, but is the result of different genetic backgrounds (M.F.Y., H.M., J.L.B., G.N.D., K.A.F. and E.M.M., unpublished results). To demonstrate whether the insertional mutation is an allele of *AG*, plants heterozygous for *ag-1* were crossed to plants heterozygous for the insertional mutation (homozygous mutant plants could not be used because they are sterile). As the *ag-1* and insertional mutants are both recessive to wild-type, and as a quarter of the resulting F1 progeny produced *ag* mutant flowers, this confirms that the two mutations are allelic. We have named the insertional allele *ag-2*.

Genetic analyses indicate that the kanamycin resistance marker encoded by the T-DNA co-segregates with the mutant flower phenotype (data not shown). This, together with the demonstration that the insertion mutation is allelic to *ag-1*, indicates that the T-DNA can be used as a molecular probe to isolate the *AG* gene. Plasmid rescue was used to isolate sequences flanking the insertion site and one of the resulting clones, pCIT505, contained plant sequences and was analysed further (Fig. 2*a*). To determine whether these sequences were derived from the *AG* genomic region, the genetic map position of the

FIG. 2 *a*, Map of the *agamous* region. *Eco*RI restriction sites are shown for a 35-kb region from the Columbia ecotype flanking the *AG* gene. Size of fragments is in kb. ▼, site of T-DNA insertion in the *ag-2* mutant. Below the restriction map, horizontal lines indicate the region contained in the plasmid-rescued clone pCIT505, and the cosmid pCIT540. *b*, Structure and restriction map of *AG* gene. The diagram below the restriction map is of introns (lines) and exons (shaded boxes); size in nucleotides is given. One cDNA extended an additional 61 nucleotides (open box). Restriction sites include: A, *Sca*I; B, *Bam*HI; C, *Nco*I; H, *Hin*dIII; N, *Nde*I; S, *Sac*I; R, *Eco*RI; T, *Pst*I; X, *Xba*I. Restriction sites in outline indicate sites in exon sequences. ▼, site of the 35-kb T-DNA insertion in *ag-2* allele. Arrow, direction of transcription. *c*, Nucleotide sequence of *AG* cDNAs and the deduced amino-acid sequence for the open reading frame. Nucleotide 1 corresponds to the first nucleotide in the longest isolated cDNA and nucleotide 1,043 is the site of polyadenylation. The region preceding nucleotide 1 was derived from genomic sequence. ▼, position of intron sequences as deduced from a comparison of cDNA and genomic sequence data. *, position of the translational initiation codon for each of the *B. napus* genes.

METHODS. Cosmids were isolated from genomic libraries of nuclear DNA prepared from the Columbia and Landsberg *erecta* ecotypes of *Arabidopsis*. This DNA was partially digested with *Sau*3A, size fractionated by sucrose gradient centrifugation, ligated to the vector pCIT30 and packaged. Plasmid pCIT30 was derived from the plasmid pMON200 (ref. 26) by replacing the kanamycin resistance gene with a fragment that encodes hygromycin resistance. Plasmid rescue was achieved by digesting DNA from homozygous *ag-2* mutant plants with *Sal*I, followed by ligation and transformation into *Escherichia coli*. The digest with *Sal*I produces a fragment containing an *E. coli* origin of replication and the ampicillin resistance (Amp^r) gene encoded by the T-DNA, as well as plant sequences flanking the insertion[28]. Plasmid pCIT505 was placed on the RFLP map of Chang *et al.*[14] using an *Eco*RI RFLP and found to reside at about the same position as *ag-1*. To map directly pCIT505 relative to *ag-1* recombinants derived from a cross between Landsberg *erecta* (Ler) and Niederzenz (Nd-O) ecotypes that included the *ag-1* mutation were analysed. Plants heterozygous for the *ag-1* mutation (*ag-1* (Ler)/+(Ler)) were crossed to plants that were wild-type for *AG* in the Nd-O background (+(Nd-O)/+(Nd-O)). The resulting F1 progeny that were heterozygous for the *ag-1* mutation (*ag-1* (Ler)/+(Nd-O)) were allowed to self-fertilize and DNA was isolated from the F2 plants that displayed the *ag* phenotype (*ag-1*/*ag-1*). DNA blots were prepared and hybridized with probes revealing *Eco*RI and *Bgl*II RFLPs. The cDNA library was prepared from 2 μg poly(A)$^+$RNA isolated from immature floral buds[3,20] before stage 12 using the Stratagene kit. After size-selection of the cDNA (>400 bp) *Eco*RI linkers were added before ligating to the vector λgt10 and packaging using Gigapack gold (Stratagene). Many cDNA clones (3×10^6) were obtained, a portion of which were screened with a probe derived from the region flanking the T-DNA insertion site in *ag-2* mutant plants. Twenty seven of the longest independently isolated cDNAs were subcloned and fully or partially sequenced. DNA sequence analysis of one of these clones, pCIT559, demonstrated that it contained the fourth (138 base) intron. All of the other cDNAs seemed to represent the same fully processed RNA. Sequence analysis was performed on double-stranded plasmids using the USB Sequenase Kit. Both strands of cDNAs and the corresponding genomic region were sequenced.

sequences in pCIT505 was determined by restriction fragment length polymorphism (RFLP) analysis[14]. No crossovers were observed between a pCIT505-linked polymorphism (Fig. 2*a*) and the *ag-1* mutation in 118 meiotic products scored, indicating that this cloned segment maps less than two centimorgans from the *AG* gene. Taken together, these results suggest that the T-DNA is inserted in or near the *AG* gene and that we have recovered DNA sequences from this region. The pCIT505 plasmid was then used as a probe to screen a cosmid library of wild-type *Arabidopsis* sequences and several clones were isolated and characterized. One of these cosmids, pCIT540 (Fig. 2*a*), when introduced into the genome of homozygous *ag-2* mutant plants, complemented the mutation and the resulting flowers appeared to be of wild type, with stamens and carpels (Fig. 1*b*). As the T-DNA insertion has been stably maintained through eight generations, and the introduced sequences restore a wild-type flower phenotype to this stable strain, it seems that this region indeed contains the wild-type *AG* gene.

Nucleotide sequence

Restriction fragments spanning the T-DNA insertion site were used to probe a complementary DNA library prepared from RNA isolated from wild-type *Arabidopsis* flowers. Only one class of cDNA clones spanned the T-DNA insertion site. The nucleotide sequence of several overlapping cDNA clones and the corresponding genomic region was determined (Fig. 2*c*). These results indicate that this gene contains at least nine exons ranging in size from 42 to 235 bases, and eight introns ranging in size from 84 to 2,985 bases (Fig. 2*b*). Sequence analysis of the T-DNA-plant junction fragment indicates that the foreign DNA in the *ag-2* allele is inserted in the 2,985-base intron (Fig. 2*b*).

To confirm that these sequences represent the *AG* gene, genomic fragments were isolated and sequenced from the EMS-generated mutant *ag-1*. The *ag-1* mutation was induced in the same genetic background, Landsberg *erecta*, from which we have isolated and characterized the wild-type sequences. This analysis revealed a single nucleotide change that is presumably responsible for the *ag-1* mutant phenotype. This nucleotide substitution changes the AG dinucleotide to AA at the acceptor site of the fourth (138-base) intron shown in Fig. 2*b*.

The deduced protein product contains at least 285 amino-acid residues, although from analysis of the sequences it seems that none of the cDNA clones are of full length. As the deduced open reading frame continues to the 5′ end of the longest cDNA, and a translational initiation codon has not been identified, the full-length AG protein could be slightly longer. But many attempts with primer extension, anchored polymerase chain reaction and the screening of two different cDNA libraries have been unsuccessful at obtaining longer clones. Nearly all of the isolated cDNAs end within a region of a few nucleotides, suggesting that the RNA may have a secondary structure that prevents extension beyond this region. As the longest cDNAs are of 1,043 base pairs (bp) and the polyadenylated messenger RNA is close to 1.1 kilobases (kb) in length (see below), these cDNAs are of nearly full length. We have recently isolated the two presumed *AG* homologues from the allotetraploid mustard *Brassica napus* and each of these genes contains a translational initiation codon corresponding to the TCG codon at nucleotides 112-114 of the *AG* cDNA sequence (M.F.Y., H.M. and E.M.M., unpublished results). This indicates that all the evolutionarily conserved sequences of the *Arabidopsis* gene have been identified.

The deduced *AG* amino-acid sequence was used to search the database of protein sequences using the program of Lipman and Pearson[15]. The AG protein shares significant sequence similarity to a class of transcription factors from humans[16] and yeast[17,18], and to the product of a recently isolated *Antirrhinum* homeotic gene[19] (see Fig. 3).

FIG. 3 Amino-acid sequence comparison (single-letter code). An alignment is shown for the deduced amino-acid sequences for the gene products from *Arabidopsis thaliana* (AG), *Antirrhinum majus* (DEF A), humans (SRF) and yeast (MCM1, ARG80). Identical residues between AG and each of DEF A, MCM1 and SRF are shown below, as are the fractions of identical amino acids shared by these proteins. Numbers to the left of each sequence indicate the position of the first amino acid shown for each protein.

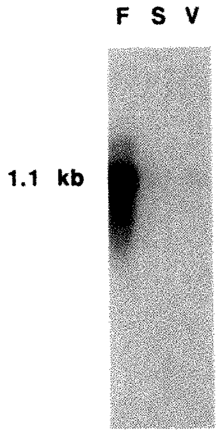

FIG. 4 RNA blot. An autoradiogram is shown for an RNA blot hybridized with ^{32}P-labelled *AG* cDNA. RNA was from immature floral buds (lane F), floral stems (lane S) and from vegetative tissue (lane V).
METHODS. Poly(A)$^+$RNA was isolated from *Arabidopsis thaliana* Landsberg (*er*) as previously described[29] and 2 μg each RNA type was size-fractionated on a 1.5% formaldehyde agarose gel, transferred to Hybond N nylon membrane (Amersham), and hybridized with a radiolabelled gel-isolated DNA fragment from the *AG* cDNA, pCIT565. Hybridization was in 50% formamide, 5 × SSC buffer, 10 × Denhardt's buffer, 100 μg ml^{-1} single-stranded salmon sperm DNA and 10% Dextran sulphate. The filter was washed three times in 2 × SSC, 1% SDS at room temperature and then four times in 0.2 × SSC, 1% SDS at 58 °C. The flower RNA was prepared from a collection of young floral buds before stage 12 (before the flowers open)[3,20]. Vegetative RNA was obtained by growing plants in a liquid culture for ~18 days before collection; the resulting tissue consisted of roots, stems and leaves. Floral stem RNA was prepared from floral stems with cauline leaves. The vegetative and floral stem RNA preparations also contain a small amount of floral RNA as these tissues contain immature stage-3 flowers[20]. To prove that RNA was present in the floral stem and vegetative lanes, this RNA blot was also hybridized with a cDNA specific for the *Arabidopsis* G-protein gene *GPA1* (ref. 30); this clone hybridized more strongly to the stem and vegetative RNA (lanes S and V) than to flower RNA.

RNA analysis

To study the pattern of *AG* gene expression, poly(A)$^+$ RNA was isolated from several different tissue types and hybridized with an *AG* cDNA. An RNA from flowers (length ~1.1 kb) hybridized with the *AG* cDNA probe (Fig. 4, lane F). After a much longer exposure, a similarly sized transcript was detected in RNA from inflorescence stems and whole plants before the appearance of the primary inflorescence stem (Fig. 4, lanes S and V), although the intensity of this signal was about 1% of that in flowers. The plant tissue used for these RNA isolations did contain a small number of early developing flowers[20], and it is possible that this low level of signal is the result of RNA in these developing flowers. We estimate the level of *AG* RNA to be ~10^{-4} in poly(A)$^+$ RNA of flowering apices, on the basis of both reconstruction experiments and the frequency of cDNA isolation.

To determine if *AG* expression is organ-specific, *in situ* hybridizations were performed. Sections of wild-type *Arabidopsis* flowers were prepared and probed with ^{35}S-labelled RNA synthesized from the *AG* cDNA template (Fig. 5). These results indicate that *AG* is expressed in stamens and carpels and not (or at much lower levels) in sepals or petals.

Discussion

We have isolated and characterized a flower-specific *Arabidopsis* homeotic gene, *AG*. The insertion mutant allele, *ag-2*, and the EMS-induced mutant allele, *ag-1*, both display alterations in the genomic region from which the presumed *AG* RNA is transcribed. The changes in the mutant alleles seem to interfere with normal transcription or splicing.

The deduced sequence of the AG protein shows striking similarity to the sequences of transcription factors from both humans (SRF, ref. 16) and yeast (encoded by *MCM1*, ref. 17, and *ARG80*, ref. 18), and to the deduced amino-acid sequence of a recently isolated homeotic gene (*def A*) from the flowering plant *Antirrhinum majus*[19]. In humans, the serum response factor (SRF) is thought to be required for the serum-inducible transcriptional activation of genes such as c-*fos*, a nuclear proto-oncogene of mammals[16]. In yeast, the product of the *MCM1* gene (GRM/PRTF) is a transcriptional regulator of mating-type-specific genes[21]. The region shared by these proteins spans ~56 amino-acid residues and, allowing for conservative substitutions, *AG* is ~80% similar in this region to all of these proteins (Fig. 3). This same region of SRF encodes the DNA-binding and dimerization domains[16,22]. On the basis of this sequence similarity and the *ag* phenotype we propose that the *AG* protein is a transcription factor involved in regulating genes that determine stamen and carpel development in wild-type flowers.

Like those of *Arabidopsis*, flowers of *Antirrhinum* consist of four concentric whorls of organs (sepals, petals, stamens and carpels). Mutations in the *Antirrhinum def A* homeotic gene cause the conversion of petals into sepals and stamens into carpels. This phenotype does not resemble that of *ag*, but closely resembles the phenotype of the *ap3* and *pi* mutants of *Arabidopsis*[3], suggesting that the *Antirrhinum def A* gene could be the homologue of either the *AP3* or *PI* gene of *Arabidopsis*. The *AG* gene product displays a high degree of similarity to DEF A in the DNA-binding region (Fig. 3), but not elsewhere. As the phenotypes of *Arabidopsis ag* and *Antirrhinum def A* mutants are very different, it seems likely that these genes function in completely different regulatory steps in flower development. The AG and DEF A proteins are more similar to each other than either is to the SRF, MCM1 and ARG80 proteins (Fig. 3).

We have recently isolated a family of other genes from *Arabidopsis*, some of which are preferentially expressed in flowers, that all share extensive sequence similarity to the DNA-binding regions of the SRF-MCM1 class of transcription factors (H.M., M.F.Y. and E.M.M., unpublished results). This indicates that there is a family of related genes that may act to control many of the steps in organ development in *Arabidopsis* flowers. This situation might be analogous to animal development where specific DNA-binding motifs have been adopted for different regulatory circuits. For example, *Drosophila* homeotic selector genes share the homeobox motif, the *Drosophila* gap genes all encode zinc-finger-type proteins, and genes involved in neurogenesis share the helix-loop-helix motif[23,24]. The MCM1[21] and SRF[25] gene products interact with other factors in regulating gene expression, and it is therefore possible that both AG and DEF A also interact with other factors to exert their regulatory control; some of these factors may be encoded by other homeotic genes known to exist in *Arabidopsis* and *Antirrhinum*.

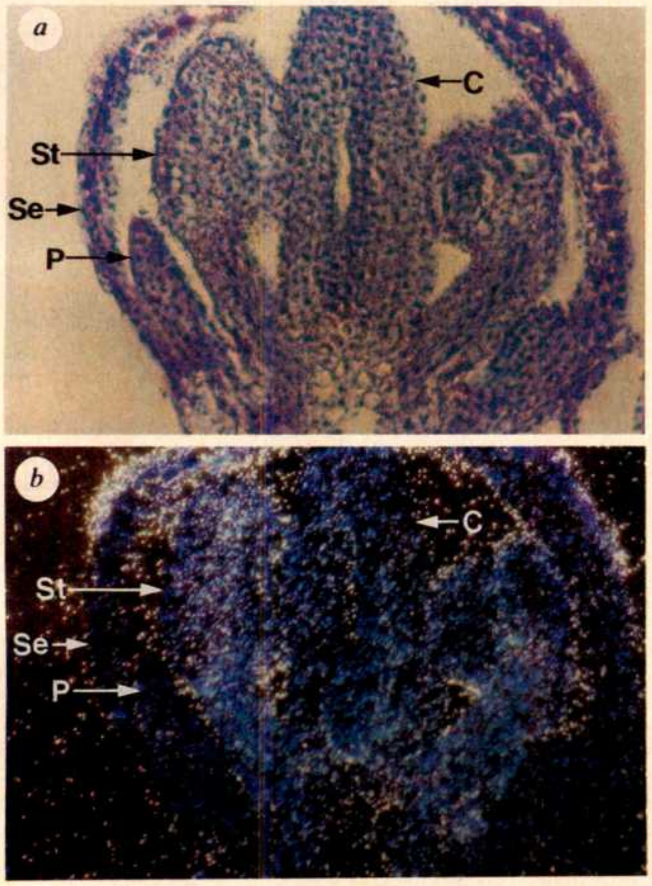

FIG. 5 *In situ* hybridization of *AG*. To determine the pattern of *AG* expression, ^{35}S-labelled antisense RNA was synthesized from an *AG* cDNA template (pCIT565), and hybridized to 8 μm longitudinal sections of stage-9 *Arabidopsis* flowers[3,20] as previously described[31]. *a*, Bright field and *b*, dark field. Arrows indicate the position of floral organs including Se (sepals), P (petals), St (stamens) and C (carpels). Hybridization of antisense RNA to the *AG* mRNA is localized to the positions of stamens and carpels and not to sepals and petals, indicating that it is in these organs that the *AG* gene is preferentially expressed. The signal over the upper portion of the sepals is observed both with sense and antisense RNA probes and therefore does not represent specific hybridization.

In addition, we used RNA blot analysis to identify the 1.1-kb *AG* mRNA and found it to be preferentially expressed in flowers. *In situ* hybridization experiments show that this RNA is localized to the stamens and carpels of wild-type flowers, the same organs that are lacking in *ag* mutants. It will be interesting to determine if the pattern of *AG* gene expression is altered in any of the other *Arabidopsis* homeotic flower mutants. ☐

Detectability of γ-rays from clumps of dark matter

George Lake

Department of Astronomy, FM-20, University of Washington, Seattle, Washington 98195, USA

If the dark matter in our Galaxy is made up of weakly interacting massive particles (WIMPs) with masses of the order of several GeV (for example, photinos or Higgsinos), γ-rays produced by their annihilation would in principle be observable[1,2]. But the expected flux[3] from a smoothly distributed dark matter halo[4,5] is much smaller than the observed diffuse background[6], and although narrow lines might be produced, their intensity would be much too low to see with the Gamma Ray Observatory (GRO)[3,7]. A complementary approach is to consider unique spatial signatures. Numerical simulations of galaxy formation[8] show that even in the central bulge of the Galaxy, the mean density of the dark matter could be equal to that of the stars. If this were so, GRO could see the Galactic Centre as a source of annihilating dark matter[1,3]. Other lumps formed as part of the hierarchical formation of the Galaxy could also produce sources that would be recognized by the shape of their continuum spectrum[2,3] and a line feature in sufficiently bright sources[3,7]. Even Geminga[9,10], the second strongest source of γ-rays at energies greater than 50 MeV, could be annihilating dark matter.

Lumps clearly formed during the hierarchical formation of the Galaxy. Clusters of galaxies are large-scale versions of this process, several per cent of their mass is contained in galaxian lumps with masses of $\sim 10^{-4} M_{\rm cluster}$ and density contrasts of $\sim 10^2$. As shown below the density contrast needs to be higher for the lumps to survive in the Galaxy, so I assume that a lower percentage of the mass is in such lumps. These lumps must either be the remnant cores of larger structures or have formed from non-gaussian initial conditions[11,12].

The dark matter in the halo has a local density[4,5] $\rho_{\rm h,0} \approx 10^{-2} M_\odot\,{\rm pc}^{-3}$. The distance to the nearest lump is $D_{\rm near} \approx (M_{\rm cl}/\eta\rho_{\rm h,0})^{1/3}$, where η is the fraction of the dark matter in lumps with cluster masses, $M_{\rm cl}$, of $M_6 \times 10^6\,M_\odot$. The flux of γ-rays with energies >50 MeV observed from this lump is

$$F = 5.8\times10^{-11}\,{\rm cm}^{-2}\,{\rm s}^{-1}(\sigma V)_{26}\left(\frac{X}{7}\right) m_{\lambda,5}^{-2} M_6^{-2/3} \times\left(\frac{\eta\rho_{\rm h,0}}{10^{-2}\,M_\odot\,{\rm pc}^{-3}}\right)^{2/3}\int_0^\infty \rho_{\rm cl}^2 r^2\,{\rm d}r \qquad (1)$$

where $(\sigma V)_{26}$ is the annihilation cross-section in units of $10^{-26}\,{\rm cm}^3\,{\rm s}^{-1}$, $m_{\lambda,5}$ is the WIMP mass in units of 5 GeV and the integral over the density in the lump, $\rho_{\rm cl}$ has units $M_\odot^2\,{\rm pc}^{-3}$. X, the average number of γ-rays with energies >50 MeV per annihilation, is fixed by e^+–e^- collider data[13] and is $7.1\,m_{\lambda,5}^{1/2}$. For the particular case of photinos[7] with masses >5 GeV

$$(\sigma V)_{26} \approx 0.1(\Omega_\lambda h_{100}^2)^{-1} m_{\lambda,5}^{-2} \qquad (2)$$

where h_{100} is the Hubble constant, H, in units of $100\,{\rm km\,s^{-1}\,Mpc^{-1}}$, and Ω_λ is the fraction of the closure density in WIMPs.

I adopt a density profile appropriate for lumps that have undergone mutual collisions and tidal shocking by the disk of the Galaxy[14]

$$\rho_{\rm cl} = \frac{\rho_0}{(1+r^2/r_c^2)^2}; \qquad \int_0^\infty \rho_{\rm cl}^2 r^2\,{\rm d}r = 2.3\overline{\rho_{1/2}}M_{\rm tot} \qquad (3)$$

where $M_{\rm tot}$ is the total mass, $\overline{\rho_{1/2}}$ is the mean density inside the half-mass radius, and r_c is a core radius.

The density $\overline{\rho_{1/2}}$ constrains the redshift of dissipationless formation for the lumps[15] and determines their ability to survive in the Galaxy. When galaxies form without dissipation, they reach maximum expansion and turn around when their density is a factor of 5.5 greater than the critical density $\rho_{\rm crit} = 3H^2/8\pi G$, where G is the gravitational constant. If pressure is unimportant, the protogalaxy collapses by a factor of two to become bound and virialized. Hence, the relationship between the redshift of turn-around, $z_{\rm turn}$ and $\overline{\rho_{1/2}}$ is

$$(1+z_{\rm turn}) = 43 h_{100}^{-2/3}\left(\frac{\overline{\rho_{1/2}}}{1\,M_\odot\,{\rm pc}^{-3}}\right)^{1/3}$$

The density $\overline{\rho_{1/2}}$ also determines whether the lumps survive mutual collisions and tidal shocking by the galactic disk. Using the impulse approximation, one can calculate the timescale for disruption owing to mutual collisions of uniform-density spheres of mass M_l, radius r and density ρ_l (see Appendix B of ref. 16). Equating M_l to M_{cl} and ρ_l to $\overline{\rho_{1/2}}$ leads to an underestimate of the disruption timescale for the more tightly bound lumps with density profiles given by equation (3). The fractional energy change during a collision with impact parameter $d \gg r$ and relative velocity v is

$$\Delta E/E = \frac{2GM_l^2}{3\pi d^4 v^2 \rho_l} \qquad (4)$$

During the age of the Universe t_U the closest encounter will have a typical impact parameter given by $d_{close}^2 = M_l/\pi v t_U \eta \rho_h$, where $\eta\rho_h$ is the density of the colliding objects. Because the energy change is dominated by the closest encounter

$$\Delta E/E = \frac{2\pi G t_U^2 \eta^2 \rho_h^2}{3\rho_l} = \frac{\eta^2 \rho_h^2}{27\rho_{crit}\rho_l} \qquad (5)$$

where the Freidmann equations with a cosmological density parameter of unity were used to replace t_U^2 with the critical density of the Universe ρ_{crit}. Adopting $\Delta E/E = 1$ as the critical value for survival versus destruction, the survivors must have densities

$$\rho_l > \frac{\eta^2 \rho_h^2}{27\rho_{crit}} = 13\eta^2\ M_\odot\ \text{pc}^{-3} \qquad (6)$$

When the density in the lumps satisfies this inequality, the dominant disruption mechanism becomes tidal shocking as they pass through the disk[17]. This has a timescale, $t_{shd} = 10^{10}$ $(\overline{\rho_{1/2}}/10 M_\odot\ \text{pc}^{-3})$ yr. With $\eta_{-2} = (\eta/10^{-2}) = 1$ and $\rho_{10} = (\overline{\rho_{1/2}}/10 M_\odot\ \text{pc}^{-3}) > 1$, the lumps survive collisions with one another and the disk. The nearest lump is at a distance $D_{near} \approx 10\ \text{kpc}(M_6/\eta_{-2})/^{1/3}$. In the general direction of the Galactic Centre, the flux is that expected from a smooth model of the halo.

The expected flux from the nearest lump is then

$$F = 6.8 \times 10^{-6}\ \text{cm}^{-2}\ \text{s}^{-1}\ m_{\lambda,5}^{-7/2} \eta_{-2}^{2/3} M_6^{1/3}$$
$$\times (\Omega_\lambda h_{100}^2)^{-1} \rho_{10} \left(\frac{\rho_{h,0}}{10^{-2}\ M_\odot\ \text{pc}^{-3}} \right)^{2/3} \qquad (7)$$

If z_{turn} were fixed rather than $\overline{\rho_{1/2}}$, there would be no dependence on the Hubble constant. The source brightness falls by a factor of two at a distance $R = 10\ \text{pc}(M_6/\rho_{10})^{1/3}$ from its centre, yielding an angular extent of ~3 arcmin. The freedom in choosing the factors in the product $m_{\lambda,5}^{-7/2} \eta_{-2}^{2/3} M_6^{1/3} \rho_{10}$ makes it impossible to predict source brightnesses. I have chosen values to yield a model where the brightest sources would appear in the Cos-B catalogue[18].

There are two immediate questions. Are there known lumps of dark matter that are potential sources? And are there any known γ-ray sources that might be identified with such lumps?

The extreme dwarf spheroidal satellites of the Milky Way, Draco and Ursa Minor, are good examples of dark lumps[19]. They are too distant to be detected, but their existence is difficult to reconcile with gaussian initial conditions[11]. Peebles[12] found that the Corona Cloud of galaxies is inconsistent with gaussian initial conditions. There are also two candidate 'dark clusters' with properties similar to those that I have assumed, one[20] with a distance of ~3.6 kpc, $M_6 = 0.5$ and $\overline{\rho_{1/2}} \approx 5 M_\odot\ \text{pc}^{-3}$ and another[21] with a distance of 5-8 kpc, $M_6 = 0.2$ and $\overline{\rho_{1/2}} \approx 3 M_\odot\ \text{pc}^{-3}$. Both of these clusters could be detected with GRO. Peebles[22] suggested that all globular clusters reside in dissipationless haloes with $M_6 \approx 100$ and $\rho_{10} \lesssim 1$, making them potential sources for GRO. Finally, I[23] invoked similar lumps so that the disk dark matter[24] could be the same as the halo dark matter.

As previously stated, several parameters have been chosen to yield fluxes comparable to the bright sources in the Cos-B catalogue. Among these, Geminga is an excellent candidate. It has an observed flux[10] of $4.8 \times 10^{-6}\ \text{cm}^{-2}\ \text{s}^{-1}$, making it the second strongest source of γ-rays with energies >50 MeV. Its angular size is <0.4°, the angular resolution of Cos-B. X-ray[25] and optical counterparts[26] have been tentatively identified with luminosity ratios $L_\gamma/L_X \approx 1{,}000$ and $L_X/L_{opt} \approx 1{,}800$. The current models are a binary pair of neutron stars[27] at a distance of <11 pc or a young pulsar at a distance of 1 kpc whose radio emission is beamed away and whose synchrotron nebulae is mysteriously absent[26]. The precise nature of this unusual source and its identification with the optical and X-ray counterparts remain uncertain. Geminga has a galactic latitude of only 4° which might make its association with the halo rather than the disk seem odd. But 9% of the total solid angle is within 5° of the disk, the surveys have concentrated on this region and the action of dynamical friction on lumps draws them toward the plane of the disk[28]. Nonetheless, some sources should be detected at high galactic latitude if this model is valid. The initial GRO survey with EGRET should accumulate 10^4 counts and determine Geminga's spectrum and spatial extent. The continuum spectrum is uniquely determined by the mass of the particle[1-3]. It will be possible to observe the narrow lines[3,7] with greater integration time or stacking of similar sources[29]. □

Free electron density in H I regions as an indicator of ionizing dark matter

D. W. Sciama*

Department of Astrophysics, Oxford University, Keble Road,
Oxford OX1 3RH, UK

It has recently been proposed[1] that the free electrons giving rise to the observed dispersion of pulsar signals result mainly from photoionization induced by the decay of dark matter particles in the Galaxy. For reasons related to conservation of energy and momentum the decay photons would have a unique energy in the rest frame of the decaying particles, and in the proposed theory

---

* Present address: International School for Advanced Studies and International Centre for Theoretical Physics, 34014 Trieste, Italy.

this energy is close to 14 eV. A crucial prediction of the theory is that in regions where the dark matter density is approximately constant, the free electron density n_e in opaque H I regions should also be approximately constant, when averaged over several mean free paths for the ionizing photons. The determination of an accurate distance for the pulsar PSR1451-68 (ref. 2), in combination with its known dispersion measure and with previous observations of two other pulsars with accurate distances, leads to a successful test of this prediction.

The dark matter particles concerned are likely to be neutrinos of non-zero rest mass. It is well known that neutrinos of mass ~30 eV created by pair production in the Big Bang would possess the critical cosmological density if the Hubble constant is ~50 km s^{-1} Mpc^{-1}. Such a mass is now ruled out for electron-type neutrinos but not for μ- and τ-types. In my theory[1] the decaying neutrinos turn out to have a well defined mass m_1 of this order, 27.7 ± 0.5 eV. Such a neutrino would be expected[3] to decay into a photon and a neutrino of another type and lower rest mass m_2. If $m_2 \ll m_1$ the energy of the decay photon would be $\sim\frac{1}{2}m_1$, here ~13.85 ± 0.25 eV. Such a photon would just be able to ionize hydrogen.

The flux of these decay photons depends on the concentration n_ν of neutrinos and on the lifetime τ for their decay. The concentration can be deduced from the observed rotation velocity of the Galaxy, and is $n_\nu \approx 5\times10^7$ cm^{-3} (ref. 1). For a decay photon energy of ~14 eV the interstellar medium would be highly opaque (for a neutral hydrogen density of ~0.1 cm^{-3} the mean free path is ~1 parsec), and the photoionization equilibrium is then simply

$$\frac{n_\nu}{\tau} = \alpha n_e^2 \qquad (1)$$

where α is the appropriate recombination coefficient. If this mechanism is to account for the value of n_e implied by observed pulsar dispersion measures, ~0.05 cm^{-3} in H I regions near the Sun[4], τ must be ~10^{23} s (ref. 1). The standard electroweak model gives[3] a much larger value of τ, but various non-standard models are under investigation[5,6] which could give the required value.

Here I am primarily concerned with the value of n_e within a few hundred parsecs of the Sun, but will first mention the implications of equation (1) for more distant regions of the Galaxy. The recombination coefficient is expected to be fairly constant; it depends on the kinetic temperature T of the electrons, approximately as $T^{-1/2}$. Therefore, $n_e \approx T^{1/4}$, a weak dependence. Moreover, in the heating regime of concern, T would not be expected to deviate from 10^4 K by more than a factor of about two in the intercloud medium over large regions of the Galaxy[7]. I can therefore assume that α is constant.

I now consider the variation of n_e with galactocentric radius r and height z above the galactic plane. Following the analysis of the pulsar data by Lyne, Manchester and Taylor[8], $n_e \approx 1/(1+r/a)$, where the core radius a is $\sim r_\odot$. Equation (1) then implies that $n_\nu \approx 1/(1+r/a)^2$. This leads to a test of the theory, because the r-dependence of n_ν influences the rotation curve of the Galaxy. In fact, there is good agreement with the observed rotation curve[9]. As regards the dependence of n_e on z, one would expect to find an essentially constant n_e at heights less than the scale height of the neutrino distribution. But this would clearly cease to be true at the height where the total gas density becomes less than the constant value of n_e implied by equation (1). Above this height the gas must cease to be opaque, and the assumption of local photoionization equilibrium would break down. Above this point n_e would be essentially equal to the total gas density. Recent observations of the dispersion measure of pulsars in globular clusters up to 20 kpc above the plane indicate that this transition layer occurs at $z \approx 600$ pc (A. G. Lyne, P. Salucci and D.W.S., manuscript in preparation).

In the region a few hundred parsecs from the Sun, one would expect n_ν to be approximately constant and τ to be exactly constant, being determined by considerations of elementary-particle physics. Thus n_e should be independent of position in opaque regions near the Sun, when averaged over several mean free paths, that is, over several parsecs. By contrast, if the ionizing photons were produced by the relatively widely separated O or B stars, and were subject to complex and position-dependent absorption effects, one would expect to find that the n_e in H I regions derived from the pulsar dispersion-measure data differ for the line segments to different pulsars.

Two of the pulsars for which the free electron densities are known and for which accurate distances have been determined from parallax measurements, PSR0950+08 and PSR0823+26, were recently discussed by Reynolds[4]. The line segments involved are separated by ~28°, and do not intersect any known H II regions. The inferred mean values of n_e were 0.023 cm^{-3} and 0.054 cm^{-3}, respectively. Reynolds[4] pointed out that a correction is necessary for the part of the line of sight that passes through the low-density bubble[10] immediately surrounding the Sun. This bubble contains X-ray emitting gas at a temperature of ~10^6 K and at a correspondingly low density. The correction is important for the first pulsar and Reynolds[4] concluded that the gas responsible for its dispersion measure must be confined primarily to the outer 47 pc of the line segment, leading to an electron density in that region of ~0.056 cm^{-3}. By contrast, the correction for the second pulsar is small. Thus essentially the same value of n_e in normal H I regions was derived for both line segments, ~0.05 cm^{-3}. Reynolds also concluded, from a detailed study of the O and B stars near these line segments, that these stars were probably not mainly responsible for the ionization along the segments, but could have contributed ~10–20% of the observed ionization.

Using the newly determined[2] distance for PSR1451−68 (450 ± 60 pc) and the dispersion measure, the electron density is 0.019 ± 0.003 cm^{-3}. This value is much smaller than 0.05 cm^{-3}, and correction for the local bubble (the radius of which is <50 pc in the direction of this pulsar)[10] would not make much of a difference. My hypothesis thus requires another suitably large bubble along the line of sight to this pulsar. The galactic coordinates of PSR1451−68 are $l \approx 315°$, $b \approx -8.5°$. This line of sight passes right through loop I, a well-known nearby supernova remnant. The position and geometry of this loop are clearly shown in Fig. 2 of ref. 10. To correct for the presence of this loop, I assume a path length of 300 pc, and adopt $n_e \approx 10^{-2}$ cm^{-3} (refs 11, 12) along this segment. This low density is associated with the high temperature of this X-ray emitting region. The contribution to the dispersion measure is therefore ~3 cm^{-3} pc. As the observed dispersion measure is 8.6 cm^{-3} pc, I conclude that the final ~100 pc of path length through a normal H I region[13] to the pulsar contributes ~5.6 cm^{-3} pc. Thus n_e in the section of the path through the normal H I region ~0.056 cm^{-3}, in good agreement with the corresponding quantity for the first two pulsars with well determined distances, and with the prediction of my theory.

The most direct observational test of the hypothesis would be to search for an unidentified line in the background at an energy of ~14 eV. This line would be produced by decaying particles in the immediate vicinity of the Sun, so that its strength F can be predicted only in relation to an understanding of the local interstellar medium. This problem is discussed elsewhere[14], where I obtained the estimate $F \approx 2\times10^3$ cm^{-2} s^{-1}.

The necessary narrow-band observations in the far ultraviolet have not so far been carried out. The upper limit for the flux of a line at ~14 eV derived from the broad-band observations of Holberg[15] is ~3×10^4 cm^{-2} s^{-1}, which is compatible with my estimate.

An attempt to search for a line in the background in the vicinity of 14 eV is being planned in collaboration with S. Bowyer and R. Stalio. If it is discovered at the flux level indicated here, it would place the hypothesis of decaying dark matter on a firm footing. □

Discovery of two radio pulsars in the globular cluster M15

WE report the discovery of two radio pulsars, 2127+11B and 2127+11C, in the globular cluster M15 (NGC7078), which also contains the 110-ms pulsar 2127+11A (ref. 1). Although only twenty globular cluster pulsars are known at present, the detection of three pulsars in a single cluster suggests that there might be a large total population of these objects, which would make them powerful probes of the dynamics and evolution of globular clusters. One of the new pulsars, 2127+11C, is in a highly eccentric binary system with an 8-hour period. It is thus similar to the famous PSR1913+16 system[2], and study of the pulse arrival times can be expected to provide tests of general relativity, including gravitational wave emission. The companion of PSR2127+11C is probably either another neutron star or a massive white dwarf, suggesting that the core of M15 contains a high density of massive stellar remnants.

The initial observations were made using the 305-m Arecibo radio telescope at a central frequency of 430 MHz and a 10-MHz receiver bandwidth. The data were sampled at an effective rate of 1.974 kHz using the Arecibo 40-MHz three-level correlation spectrometer in a manner identical to that used in the discovery of PSR2127+11A (ref. 1). The discovery observations were made on 26 December 1988 starting at 18:51 UT. The pulse search was carried out on the NCUBE/10 (California Institute of Technology), a concurrent computer having 512 central processing units interconnected with hypercube topology. Assuming a dispersion measure of 67.25 pc cm^{-3}, the measured value[1] of PSR2127+11A, a de-dispersed time series of 2^{24} points was formed by supplementing the observed 10.9 million samples with the mean value. The power spectrum was calculated using an implementation of the fast Fourier transform (FFT) algorithm for concurrent computers[2] and was searched for families of significant harmonic peaks.

Table 1 and Fig. 1 give the parameters and pulse profiles of the three pulsars detected in the 430-MHz observations. PSR2127+11A was clearly detected in our first analysis of the December 1988 data. Further inspection revealed PSR2127+11B with a period of 56 ms, about twice as faint as PSR2127+11A. Subsequent timing measurements spanning 230 days indicate that PSR2127+11B is an isolated pulsar with a period derivative $\dot{P}$ of 9×10^{-18} s s^{-1}, implying a characteristic age of 1×10^{8} yr, if the observed $\dot{P}$ is due solely to magnetic braking. If, on the other hand, one assumes that the dominant effect is acceleration due to the local gravitational field, as in the case of PSR2127+11A, then the magnitude of the acceleration is 5×10^{-8} m s^{-2}. The errors quoted for PSR2127+11B in Table 1 are three times the formal errors given by the temporal fitting program used in the analysis (TEMPO). The accuracy of these measurements are limited by the coupling of the timing residuals owing to a position error (a sine wave of period one year) and a $\dot{P}$ error (quadratic drift) over the limited observation period of 230 days.

PSR2127+11C was discovered using an algorithm specifically developed for detection of pulsars in binary orbits. The variable Doppler shift due to the orbital acceleration can spread the signal power over multiple frequency bins, resulting in a loss in sensitivity, particularly for fundamentals or harmonics with millisecond periods. In our algorithm, samples were inserted or deleted in the time series to compensate for a presumed acceleration. To reduce the computational demands of the search, we assumed a constant acceleration. A range of accelerations from -19.2 m s^{-2} to $+19.2$ m s^{-2} was explored using 2^{24}-point transforms, corresponding to the acceleration experienced by a pulsar in a circular orbit with 1-d period and a 1-$M_\odot$ companion. A series of 2^{22}-point transforms was also calculated for accelerations up to 203 m s^{-2}, corresponding to a 1-$M_\odot$ companion and a 4-h circular orbit. PSR2127+11C, with a period of 30.5 ms, was initially found in a 2^{24}-point transform at an acceleration of -9.5 m s^{-2}.

Timing measurements were begun to determine the keplerian parameters of the PSR2127+11C orbit. Recording of the raw data stream on magnetic tape allowed us to extract timing information for all three pulsars from the same data. Because of the faintness of PSR2127+11C, an integration time of $\geqslant10$ minutes was required for detection. This necessitated an acceleration search for each observation to compensate for orbital motion and to obtain the correct apparent pulsar period. The determination of the orbital period was also complicated by the limited duration (3 h) over which the cluster can be observed by the Arecibo telescope. The orbital period was found to be 8.05 h, indicating that it would take a minimum of 6 weeks for a complete cycle of observable orbital phase. In Fig. 2, we display the apparent pulsar period at the midpoint of each observation as a function of the orbital phase for observations taken primarily over an 8-week period. The eccentricity of the orbit is immediately apparent.

Using the velocity curve in Fig. 2 for an initial estimate of the orbit, we analysed the pulse arrival time on 17 observations taken during May 1988. The resulting keplerian parameters, surprisingly similar to those of PSR1913+16 (ref. 2), are given

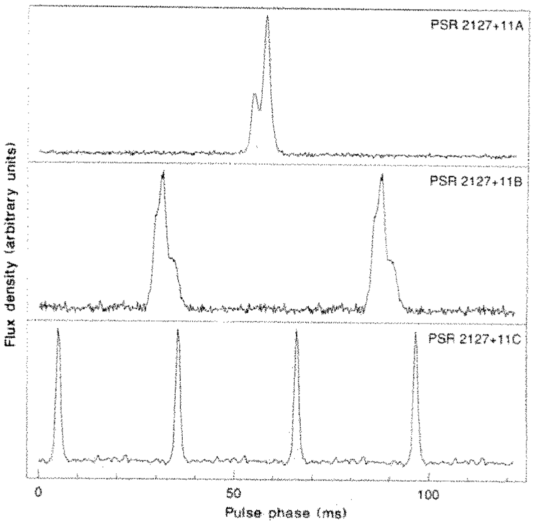

FIG. 1 Average pulse profiles for the three known radio pulsars in globular cluster M15. The time resolution is 500 μs.

TABLE 1 Pulsar parameters

Timing parameters		2127+11A	2127+11B	2127+11C
Epoch (JD)	T_0	2,447,213.15	2,447,632.9906	2,447,660.9089
Pulse period (ms)	P_0	110.66470954 (1)	56.13303358 (1)	30.529 (1)
Period derivative (10^{-18} s s^{-1})	$\dot{P}$	−20 ± 1	8.8 ± 1.1	—
Right ascension (1950.0)*	α_{m15}	−1.95 ± 0.15″	+3.86 ± 0.15″	—
Declination (1950.0)*	δ_{m15}	+0.6 ± 0.3″	−0.8 ± 0.6″	—
Dispersion measure (pc cm^{-3})	DM	67.25 ± 0.05	67.25 ± 1.0	67.25 ± 1.0
Flux density (mJy)	S_{430}	1.7 ± 0.4	1.1 ± 0.4	0.6 ± 0.2
Orbital period (s)	P_b	—	—	28,969 ± 1
Projected semi-major axis (light s)	$a_1 \sin i$	—	—	2.52 ± 0.01
Eccentricity	e	—	—	0.680 ± 0.003
Longitude of periastron (deg)	ω_0	—	—	316.4 ± 1.0
Epoch of periastron (JD)	T_0	—	—	2447632.46720 (5)
Mass function ($M_\odot$)	f	—	—	0.15

Timing parameters for PSR2127+11A, B and C. The values given for PSR2127+11A are those reported in Wolszczan *et al.*[1] and are consistent with the results of our 430-MHz observations. The values for PSR2127+11B are based on 430-MHz observations spanning 230 days. The keplerian orbital parameters for PSR2127+11C are based on 17 days of pulse arrival timing. Numbers in parentheses indicate the uncertainty in the last significant figure.

* Positions relative to the centre of globular cluster M15 ($\alpha = 21^h\,27^m\,33.35^s$, $\delta = 11°\,56'\,48.8''$)[16].

in Table 1. If the secondary is another neutron star, the estimated orbital decay time and the advance of periastron will be 2×10^8 yr and 4° yr^{-1}, similar to those of PSR1913+16. The PSR2127+11C system should thus provide tests of general relativity in the strong-field limit, including gravitational wave emission, as does PSR1913+16. The errors quoted in Table 1 are our best estimates of the uncertainty arising from the limited time span of observations. A significantly more accurate measurement of the pulsar parameters, including a precise determination of the advance of periastron, is in progress using approximately nine months of timing observations.

Constraints can be placed on the pulsar and companion masses (M_p and M_c) by determining the mass function f, which depends on the apparent size of the pulsar's orbit and the orbital period. The value of the mass function for the 2127+11C system is $f(M_p, M_c) = (M_c \sin i)^3/(M_p + M_c)^2 = 0.15 M_\odot$. Assuming $M_p = 1.4 M_\odot$ for PSR2127+11C, the minimum mass of the companion is 0.94 $M_\odot$. For $M_p = M_c = 1.4 M_\odot$, the inclination angle i of the orbital plane to the line of sight would be 49°, close to the median inclination angle of 60°. Given the measured orbital parameters, the distance of closest approach is of the order of $R_\odot$ for inclination angles corresponding to a 1-$M_\odot$ companion. A main-sequence companion is therefore ruled out, and the companion is most likely a second neutron star or a massive white dwarf.

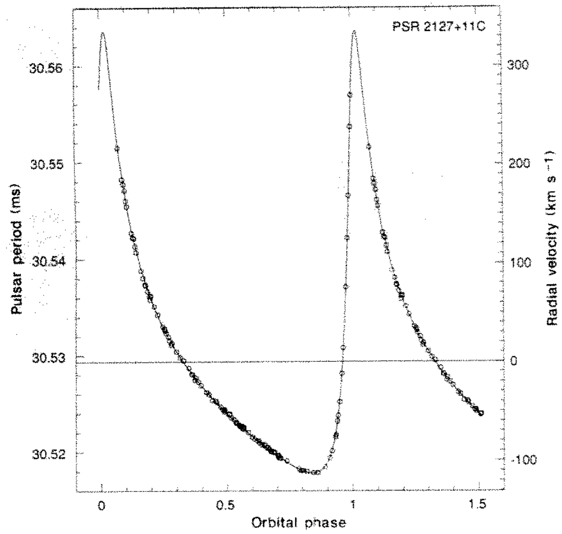

FIG. 2 Velocity profile and observed Doppler-shifted pulse periods as a function of orbital phase for PSR2127+11C. The solid line is the apparent pulse period derived from the five keplerian orbital parameters given in Table 1.

The discovery of three pulsars in a single cluster suggests that pulsars are abundant in globular clusters. Kulkarni *et al.*[4] have quantitatively analysed the results of the major surveys of cluster pulsars and conclude that a typical rich cluster contains about 100 active pulsars, most of which will be undetectable owing to the great distances to the clusters. Assuming a distance of 10 kpc to M15, the radio luminosities of PSR2127+11A, B and C are respectively 170 mJy kpc^2, 110 mJy kpc^2 and 60 mJy kpc^2. These luminosities are well above the minimum luminosity of 1 mJy kpc^2 for field pulsars. Hence with increased sensitivity, other pulsars ought to be detectable in M15. We are now analysing all our data (>50 h of observations) in an effort to locate fainter pulsars.

The discovery of the binary pulsar, 2127+11C strongly suggests an abundance of massive stellar remnants in the core of M15. According to the standard scenario, in some previous phase, PSR2127+11C must have been in a binary system with a non-degenerate companion. We rule out 2127+11C being a primordial binary because the formation of such systems is inevitably associated with a large systemic motion ($\gtrsim$200 km s^{-1})[5-7] which would have resulted in the expulsion from the cluster. Consequently, the companion is probably the result of a capture interaction. Alternatively, PSR2127+11C could have been a solitary spun-up pulsar (like PSR2127+11B) that experienced an exchange collision with a binary system. The large observed eccentricity indicates that an exchange may have taken place recently.

Various authors have argued[8-10] that accretion-induced collapse (AIC) of white dwarfs can produce pulsars. AIC scenarios invoke massive C+O white dwarfs or O-Ne-Mg white dwarfs and thus, even if AIC mechanism were to be operative (see Verbunt *et al.*[11] for a discussion of the considerable theoretical and observational difficulties with this mechanism), the discovery of PSR2127+11C implies an abundance of these white dwarfs. Such white dwarfs evolve from massive main-sequence stars ($M \leq 8 M_\odot$). Thus in the framework of either the standard or the AIC model we conclude that, in the past, M15 contained many massive stars. To achieve reasonable rates for exchange or capture interactions, the remnants of these massive stars must have aggregated in the core of M15 by mass segregation. Even taking this effect into account, very steep initial mass functions ($\propto M^{-\alpha}$, $\alpha \geq 3.5$) are ruled out for M15 because they predict insufficient numbers of massive white dwarfs and neutron stars. A flatter initial mass function also explains the large abundance of pulsars inferred from other observations[4]. We note, however, that some recent theoretical studies[12] suggest steep initial mass functions for most clusters that have survived to the present.

Most tidal-capture binaries (those captured by transfer of kinetic energy to stellar deformation) are expected to be formed with an orbital radius of $\sim R_\odot$, and thus an orbital period of a fraction of day. A small fraction (10–30%) are expected to be wide binaries ($P_{\text{orb}} \approx 100$ d) formed by capture of giants. The formation of single pulsars like 2127+11A and B is easily understood as resulting from the breakup of a wide binary by passing stars[13,14]. Rappaport *et al.*[15] have shown this to be a very effective mechanism for breaking up wide binaries in the especially high-density collapsed core of M15. The tidal interaction model predicts that there should be 3–10 times more compact binaries than isolated or wide-orbit binaries, whereas we detected only one compact binary and two isolated pulsars. Selection effects may have prevented detection of a larger number of short-orbital-period systems in our survey and a quantitative analysis of them will be presented elsewhere. ☐

Coexistence of two liquid crystalline phases in poly(γ-benzyl-α, L-glutamate) solutions

J. C. Horton, A. M. Donald* & A. Hill†

Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE, UK

IN 1956, Flory[1] proposed a phase diagram for rod-like molecules of the form shown in Fig. 1. Since then, most of the major features of this diagram have been verified experimentally[2]. In particular, the two-phase 'chimney' is now well established. One feature that has not previously been established, however, is the slight maximum (the 'cap') in the phase boundary on the high-concentration side of the chimney. Flory[1] pointed out that this cap should manifest itself as two coexisting liquid-crystalline (anisotropic) phases. Here we provide evidence for bulk phase separation into two such phases in a macroscopic (~0.5 g) liquid-crystal sample held in a constant-temperature bath. A distinct boundary can be seen between the two phases, and they are distinguished further under an optical polarizing microscope.

Benzyl alcohol solutions of the synthetic polypeptide poly(γ-benzyl-α, L-glutamate), chosen as a model rod-like molecule, gel at ~60 °C. Details of sample preparation can be found elsewhere[3].

We have previously found[4] evidence for separation of the gel into two anisotropic phases at ~100 °C. In that experiment a small sample was heated in a hot stage so surface effects may have been significant and the phases may not have been in equilibrium. Here we immersed small-bore test tubes containing ~0.5 g of 15% gel (molecular weight 248,000) in a constant-temperature bath. Macroscopic phase separation (with an easily visible boundary) was achieved at temperatures ~80 °C after a day or so. A room-temperature photograph (Fig. 2, left) shows a tube with the two phases clearly visible. (Cooling rapidly to room temperature does not affect the appearance of the phase separation, but the quality of the photograph is better because it is not necessary to photograph through the hot oil.)

Examination of samples of the upper and lower phases in an optical polarizing microscope shows that both are anisotropic. The lower phase is strongly coloured and shows definite 'fingerprinting'[5] with a periodicity of ~15 μm (Fig. 2, lower right). The upper phase takes the form of a black and white speckle (Fig. 2, upper right). The two phases are clearly distinct; this is clear evidence for the equilibrium coexistence of two liquid-crystalline phases.

The phase separation takes about a day, that is, the boundary takes about a day to form. Given that the samples consist of 0.5 g of a highly viscous material, it is not surprising that a large-scale separation should take so long to occur. To find the lowest temperature at which the phase separation occurs, samples were heated at a rate of ~1 °C per day. The first separation was observed at 71 °C and examination of the lower phase showed that it was both coloured and characterized by 'fingerprints'. Previously we saw formation of the coloured phase at higher temperatures, but these results are not necessarily inconsistent because in the first experiment the heating rate was much faster, 2 °C min^{-1}, and the sample was much smaller. In the first experiment we observed the coloured phase immediately upon formation whereas in the experiments reported here it is not observed until bulk phase separation has occurred.

Russo and Miller[6] have seen evidence for the cap in the temperature dependence of fingerprint spacing at fixed concentration. As they reduced the temperature, the fingerprint spacing decreased and then at a certain temperature it began to increase again. From this they inferred that at this temperature the sample passed from the one-phase region to the two-phase cap. They did not actually see the second phase.

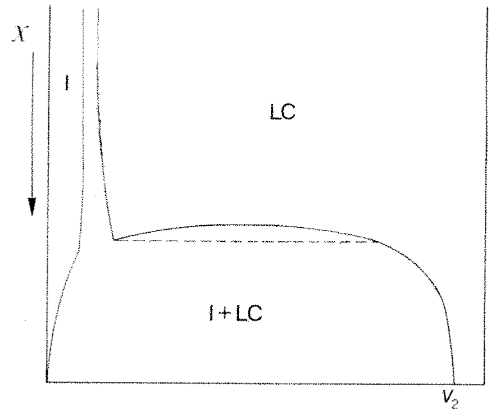

FIG. 1 The phase diagram of rod-like molecules as described by Flory[1]. The axes are quality of solvent, χ ($\approx cT^{-1}$, where T is temperature and c is a constant) and the volume fraction of polymer, v_2. The dotted line indicates the lower edge of the 'cap'. I, isotropic; LC, liquid crystalline.

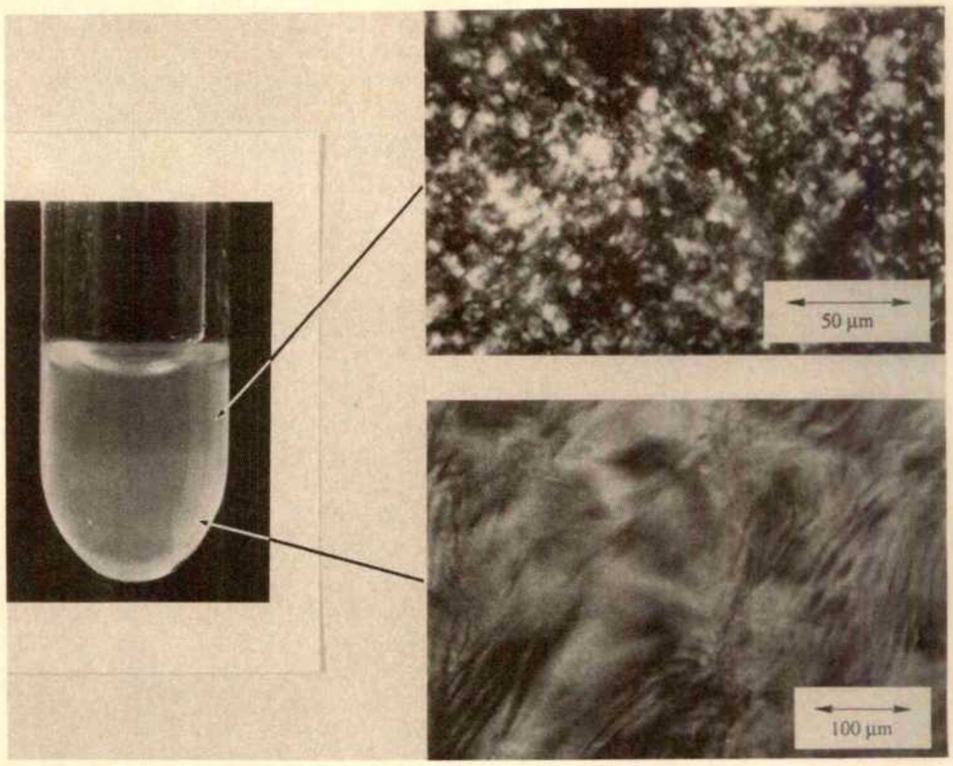

FIG. 2 Left, room-temperature photograph of the upper and lower phases, shown in the tube used for separating them. Right, the upper and lower phases seen between crossed polar filters.

The solvent used here was described by the supplier as 99% benzyl alcohol and was used as supplied. Gels were also made up with anhydrous benzyl alcohol (quoted as containing <0.005% water and supplied under nitrogen) and 99% benzyl alcohol that had been vacuum distilled in the laboratory and stored over a molecular sieve. No sample made with either of these latter solvents showed any sign of phase separation at any temperature. This can be attributed to the reduction of the solvent quality by water. Russo and Miller[7] have analysed the effect of a non-solvent on the Flory phase diagram and, for simplicity, displayed the results on a binary phase diagram rather than a ternary one. They found that the phase boundary is moved up for increasing amounts of non-solvent and also that the shape of the cap is altered slightly. The trace water in our system seems to lead to a greater range of temperatures between the gel's melting point (~60 °C, ref. 3) and the one-phase region, LC, and hence a larger two-phase region in which phase separation is possible once the crystals have melted. To verify this, we made up a sample of gel using anhydrous benzyl alcohol that had been deliberately contaminated with water (2% volume by volume). Again we observed phase separation, confirming that trace amounts of water shift the position of the phase diagram relative to the gel melting point and make the phase separation possible. Phase separation in the 'dry' system cannot be achieved because the melting point of the crystals (and hence the gel) is inside the single-phase region. Phase separations involving the isotropic phase (in different parts of the phase diagram) are now being investigated. □

Depletion of H_2O_2 in a Greenland ice core: implications for oxidation of volcanic SO_2

MAJOR volcanic eruptions inject large quantities of sulphur compounds into the atmosphere[1]. A principal component is sulphur dioxide; subsequent oxidation of SO_2 in the atmosphere to sulphuric acid aerosol may lead to climate perturbations[2]. Here we present evidence to suggest that SO_2 oxidation may occur at high latitudes by reaction with H_2O_2. Variations in sulphate and H_2O_2 concentrations in four sections of a Greenland ice core (corresponding to four volcanic events) show that high sulphate concentrations, from volcanic fallout, are accompanied by depletion of H_2O_2. This suggests that some of the volcanic sulphur was still in the form of SO_2 when it reached Greenland, and was then oxidized by H_2O_2 in Greenland precipitation. As SO_2 oxidation in the stratosphere is very slow, volcanic events that inject SO_2 into the stratosphere could produce large depletions of distant H_2O_2 reservoirs when the material is later reinjected into the troposphere.

During volcanic eruptions sulphur compounds, predominantly H_2S and SO_2, are released into both the troposphere and stratosphere. Once in the atmosphere, H_2S is very rapidly converted into SO_2 (ref. 3). Sulphur dioxide is then oxidized to sulphate and sulphuric acid particles by reactions occurring in the gas phase, in the aqueous phase, and/or on aerosol surfaces[4–6]. The sulphate aerosol plays a significant part in short-term climate change after volcanic eruptions, by scattering and absorbing solar radiation[7], which results in surface temperature cooling[8,9]. In fact, small but sulphur-rich eruptions may produce climate changes similar to or even larger than much more voluminous silicic, sulphur-poor eruptions[8,10,11]. As sulphur compounds are released in a reduced or incompletely oxidized form, an accurate knowledge of the production rate of sulphate aerosol from SO_2 is important for assessing the climate impact. In the aqueous phase, H_2O_2 is believed to be the most efficient oxidizing agent of SO_2 because, unlike most other species, oxidation kinetics of SO_2 by H_2O_2 are only slightly slowed down by a decreasing pH in an open system[12,13]. Here we present a detailed record of H_2O_2 and SO_4^{2-} concentrations in four volcanic acidity layers from an ice core drilled in 1985 at Site A, central Greenland (71° N, 36° W).

Solid electroconductivity measurements were performed to locate high-conductivity layers, which presumably represent high-H^+ layers associated with volcanic events[14]. For chemical analyses we sampled these high-conductivity layers, as well as adjacent parts of the core corresponding to a period of 3 to 4 years before and after each eruption, at intervals of 4-7 cm (~2 months) using ice-cleaning procedures similar to those described by Spencer *et al.*[15]. Anion (Cl^-, NO_3^-, SO_4^{2-}) and cation (Na^+, NH_4^+, K^+, Mg^{2+}, Ca^{2+}) concentrations were measured by ion chromatography. We determined the peroxide content of the samples using the fluorometric technique originally developed by Guilbault *et al.*[16] and later modified by Lazrus *et al.*[17]. For these samples, no distinction has been made between organic and inorganic peroxides so that all values for 'peroxide' in the samples refer to total inorganic and organic peroxides. The precision is of the order of 10% for ion chromatography measurements and 7% for peroxide measurements.

A preliminary depth-age relationship for the ice core was determined using density measurements and snow accumulation rates[18]. Comparisons with particle concentration measurements in a second core drilled at site A in 1985 (E. Mosley-Thompson, personal communication) confirmed that the high-acidity layers at 22.6, 36, 70.5 and 80.5 metres in the core correspond to the eruptions of Hekla (1947), Katmai (1912), Tambora (1815) and Laki (1973), as listed in Table 1. Variations in SO_4^{2-} and H_2O_2 as a function of depth for these four volcanic eruptions are shown in Fig. 1. Sulphate values have been corrected for the sea-salt contribution[19] and thus represent the non-sea-salt sulphate only.

Seasonal variations in the Cl:Na ratio in polar snow have been observed[19] and we used these to identify summer periods (Fig. 1). Both SO_4^{2-} and H_2O_2 exhibit seasonal variations in polar snow with peaks in the summer[19,20]. At depth, seasonal variations in the peroxide profiles are less clear (Fig. 1) because of the diffusion of the peroxide in the ice[21]. Significant enhancements in SO_4^{2-} concentrations in the Greenland ice are observed

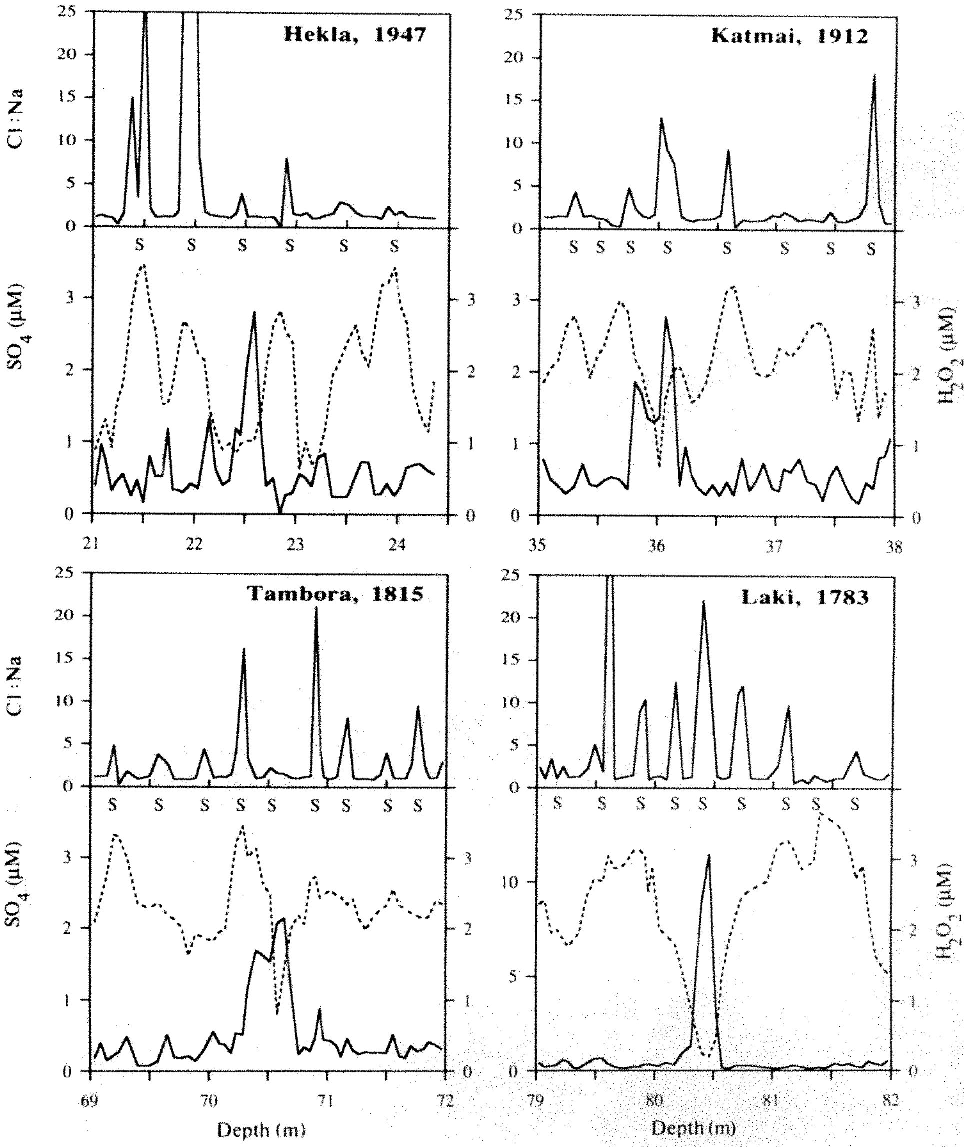

FIG. 1 Variation of non-sea-salt SO_4^{2-} concentration (—) and H_2O_2 concentration (----) as a function of depth for four sections of the Site A, Greenland ice core. Summer periods, based on variation of Cl:Na ratio are indicated by S.

TABLE 1 Sulphur conversion rates and chemical lifetimes

Volcanic events	SO_2 degassed* ($\times 10^{10}$ kg)	H_2O_2 loss (μmol l^{-1})	SO_4(volc) (μmol l^{-1})	%SO_2 (%)	Travel time (d)	Conversion rate ($\times 10^{-1}$ % d^{-1})	Lifetime (d)
Hekla 1947 Iceland	0.5	0.8	1.1	70	2-6†	0.7-2	5-15
Katmai 1912 Alaska	1-3	0.65	1.25	50	5-10‡	0.7-1.6	6-15
Tambora 1815 Indonesia	20-40	0.2	1.35	15	100-200§	0.05-0.1	100-200
Laki 1783 Iceland	15-20	2.1	6.0	35	2-6†	2-6	2-5

owing to the deposition of volcanic sulphuric acid, with an enrichment of up to twenty times the background for the 1783 Laki eruption. For all of the volcanic events, a distinct deviation from the expected seasonal peroxide profile is evident and very strongly correlated with increased excess SO_4^{2-} attributable to the volcanic events. This pattern is observed both for high-latitude (Laki, Hekla and Katmai) and low-latitude (Tambora) eruptions although these eruptions were chemically different[11,22] and took place at different times of the year. The depletion of H_2O_2 associated with increased SO_4^{2-} indicates that part of the volcanic sulphur was present as SO_2 over Greenland at the time the precipitation was forming, and that a reaction occurred between H_2O_2 and SO_2 in the supercooled water film at the surface of ice crystals according to the following mechanism[23]

$$SO_2 + H_2O \Leftrightarrow SO_2 \cdot H_2O \tag{1}$$

$$SO_2 \cdot H_2O \Leftrightarrow HSO_3^- + H^+ \tag{2}$$

$$HSO_3^- + H_2O_2 \Leftrightarrow HOOSO_2^- + H_2O \tag{3}$$

$$HOOSO_2^- + H^+ \rightarrow H^+ + HSO_4^- \tag{4}$$

$$HSO_4^- \Leftrightarrow SO_4^{2-} + H^+ \tag{5}$$

Although we cannot rule out the possibility of H_2O_2 destruction catalysed by volcanic dust particles, all these eruptions show the same pattern despite differences in the amount of dust that reached Greenland[24]. Furthermore, simulation of atmospheric HO_2 concentrations after the El Chichon eruption[7] indicate that HO_2 concentration changes in the volcanic plume are insufficient to account for the H_2O_2 depletion. Examination of the Cl:Na ratio establishes that the acid deposition took place for a period of one year or more following the Tambora and Katmai events. However, H_2O_2 decreases are only observed during summer. Thus, the SO_2-H_2O_2 reaction appears to take place only during the summer. In the Laki layer, the extensive SO_2 emission may have completely depleted peroxide in the precipitation.

To estimate conversion rates of SO_2, we have made the assumption that all of the peroxide depletion is the result of the reaction with SO_2. According to the reaction mechanism described above, a net loss of H_2O_2 increases SO_4^{2-} concentration by the same amount. By comparing the SO_4^{2-} produced from SO_2-H_2O_2 oxidation (H_2O_2 (loss)) and the total increase in SO_4^{2-} above background (SO_4^{2-} (volc)) we can estimate the proportion of sulphur still existing as SO_2 before the SO_2-H_2O_2 reaction took place in the precipitation as

$$\%SO_2 = (H_2O_2(\text{loss}) \times 100)/SO_4^{2-}(\text{volc})$$

Thus, knowing the SO_2 proportion and assuming a reasonable travel time for SO_2 from the volcanic point source[25,26], we have estimated global SO_2 conversion rates for each of the events as conversion rate $(\%\,d^{-1}) = 1 - (\%SO_2/100)^{1/n}$ where n is the travel time in days. Calculated values of %SO_2 and SO_2 conversion rates are presented in Table 1. The %SO_2 should be regarded as an averaged proportion of SO_2 in the volcanic cloud over Greenland during the time of deposition, which is 4-12 months, depending on the event. Chemical lifetimes can be derived from the calculated conversion rates using the following equation: lifetime $(d) = [\ln(1/e)]/[\ln(1-k)]$ where k is the conversion rate ($\%\,d^{-1}$) (Table 1).

In the case of the high-latitude eruptions, the volcanic sulphur compounds were transported to the Greenland area through the upper troposphere where the SO_2 oxidation takes place primarily in the gas phase through reaction with the OH radical by the following mechanism[4]

$$OH + SO_2 + M \rightarrow HOSO_2 + M \tag{6}$$

$$HOSO_2 + O_2 \rightarrow HO_2 + SO_3 \tag{7}$$

$$SO_3 + H_2O \rightarrow H_2SO_4 \tag{8}$$

Over Greenland, the volcanic plume interacts with clouds resulting in the scavenging of SO_4^{2-} aerosol. Any SO_2 still present will react with H_2O_2. For these eruptions, our calculations indicate that 35-70% of the volcanic sulphur is still present as SO_2 by the time the plume reaches Greenland. The %SO_2 values are minimum estimates because there may have been insufficient H_2O_2 in the atmosphere to react with all of the volcanic SO_2, especially in the case of the Laki and the Katmai events where H_2O_2 concentration drops to almost zero. For these eruptions, calculated conversion rates are in the range 0.06-0.6% per day, corresponding to chemical lifetimes of the order of 2-15 days. These values are about ten times lower than those calculated near Mt Etna[27] but are very similar to those calculated for the oxidation of SO_2 in the troposphere at high latitude[28].

Sulphur compounds from the low-latitude Tambora eruption reach the high latitudes through stratospheric transport[10]. Because of the low H_2O concentration in stratospheric air, homogeneous gas-phase reactions are likely to be the main process of SO_2 oxidation[29]. McKeen *et al.*[29] proposed a stratospheric oxidation mechanism similar to the previously discussed tropospheric gas-phase reaction pathway[4]. Our data indicate that 15% of the volcanic sulphur reinjected into the troposphere over the Arctic is still present as SO_2. For the Tambora event, the SO_2 oxidation rate is of the order of 0.005-0.01% per day, which is considerably lower than rates calculated for the high-latitude events. This difference between SO_2 oxidation rates in the stratosphere and the troposphere is probably due to differences in the concentrations of OH, H_2O and O_2 or N_2, which are common third molecules for reaction (6).

These low conversion rates are consistent with the SO_2 stratospheric chemical lifetime of 100-200 days observed after the 1982 El Chichon eruption[30] and the 1974 Vulcan de Fuego eruption[31]. The SO_2 chemical lifetime in the stratosphere during non-volcanic periods, however, is of the order of one month[2]. Volcanic SO_2 injections therefore result in an increase in the SO_2 lifetime by a factor of 3-7. This difference between volcanic and non-volcanic periods cannot be explained by a direct decrease in the OH concentration owing to reaction (6) because the OH radical is recycled through the following reactions[29]

$$HO_2 + NO \rightarrow NO_2 + OH \tag{9}$$

But large SO_2 injections can lead to a lower O_3 photolysis by increasing the SO_2 opacity in the 300-nm wavelength region[2], thus indirectly affecting the OH production rate. Such a long chemical lifetime supports the hypothesis[2] of a negative feedback in volcanic-induced climate perturbation, by limiting the amount of particulate H_2SO_4 present in the stratosphere at a given time.

Oxidation of volcanic SO_2 seems to be a very slow process in the stratosphere and the SO_2 chemical lifetime is increased to several months after volcanic eruptions. The volcanic SO_2 could then be oxidized far away from the eruption site and may produce a large depletion of the H_2O_2 reservoir when this material is reinjected into the troposphere.

This peroxide depletion seems to be taking place at least on a regional scale following both high-latitude and low-latitude volcanic events. Because of the very high solubility of peroxide in water, it is very likely that this depletion is parallelled by a depletion of gas-phase peroxide. Considering that the HO_2 radical is the main source of H_2O_2 in the tropospheres[5], this may also affect the concentration or the lifetime of this reactive compound. Because of the importance of the HO_2 radical in ozone chemistry, volcanic eruptions are then likely to produce a short-term variation in both nitrogen and odd-oxygen chemistry[7]. More work will be necessary to quantify the impact on other chemical cycles in the atmosphere. ☐

The sensitivity of terrestrial carbon storage to climate change

Katharine C. Prentice & Inez Y. Fung

NASA, Goddard Space Flight Center, Institute for Space Studies, New York, New York 10025, USA

THE high correlation found between atmospheric CO_2 concentration and temperature during the past 160,000 years[1,2] implicates CO_2 as an important driving force behind changes in palaeoclimate. Changes in biological processes and circulation patterns in the oceans are believed to drive glacial-to-interglacial changes in CO_2 and thus in climate. Here we estimate the role of the terrestrial biosphere in controlling atmospheric CO_2 levels during climate perturbations. By considering the coupling between vegetation distributions and climate, we perform simulations to calculate the global geographical distribution of vegetation during the last glacial maximum, 18 kyr ago. The known changes in sea level at this time, together with the simulated climate-driven spatial arrangement of vegetation, result in a mass transfer of carbon from the terrestrial biosphere to the atmosphere ranging from 30×10^9 tonnes (30 Gt, corresponding to 15 p.p.m. CO_2) to -50 Gt (25 p.p.m.). Thus, although the biosphere may have contributed to the decrease in atmospheric CO_2 of 80 p.p.m. known to have occurred at 18 kyr (refs 1, 2), it does not seem to have been a dominant factor. For simulations run with twice the present-day CO_2 levels, strong negative feedbacks appear which remove 235 Gt of carbon (128 p.p.m. CO_2) from the atmosphere.

Bioclimate schemes relate the distribution of climates and the distribution of vegetation types, classifying climates according to their thermal and moisture attributes. The climate classes are named for vegetation types with which they have been associated. This association of vegetation and climate permits the simulation of vegetation distributions for different climates.

In an earlier study[3], the contemporary distribution of global vegetation was simulated by using a refined version of the Holdridge Life Zone Scheme[4] to classify observed 30-year mean annual temperature and precipitation[5]. The climate classes were grouped and named for the vegetation types with which they have greatest geographic coincidence[6]. Unlike earlier bioclimate predictions[7-10], resulting climate classes were named for present-day vegetation types defined by the internationally recognized UNESCO classification scheme[11] rather than for the independent and generalized vegetation groups used by the bioclimate schemes. Quantitative evaluation of the simulated distribution is thus possible because a consistent vegetation terminology is used for both observed and simulated vegetation. At 1°×1° resolution for the globe, 77% of the simulated landscape, classified as 29 vegetation types, spatially corresponded with observed vegetation. The misclassifications over 23% of the land surface generally involve climatically similar vegetation types which also have similar carbon attributes.

For the study reported here, the 29 vegetation types are combined into 14 types to reflect more generalized units of carbon storage. We apply distribution relationships developed between the 14 observed UNESCO types and the observed climatology to perturbed climates. As well as today's climates, climates at 18 kyr BP (before present) and climates for doubled CO_2 levels ($2\times CO_2$) have been simulated using the general circulation model (GCM) at the Goddard Institute for Space Studies[12]. Temperature and precipitation, simulated at a 4°×5° resolution, are linearly interpolated to $2\frac{1}{2}$°. Both the $2\frac{1}{2}$° observed and simulated distributions are then regridded to 1° without further interpolation beyond that necessary for the $\frac{1}{2}$° registration. Annual temperature and precipitation used here are calculated for each 1° gridbox by adding the difference between simulated perturbed and simulated present climates to observed 30-year mean climatologies[5]. In this way, the interpretation of bioclimate patterns is rooted in observed climatology. Land area changes as 1°-gridded surface areas emerge or submerge with altered sea level. The sea level at 18 kyr is lowered by 130 and 100 m to bracket a best estimate of 121 m (ref. 13), and the sea level for the $2\times CO_2$ simulation is raised by 2 m, a likely upper estimate[14].

To evaluate the possible impact of the perturbed biosphere on the carbon cycle, we calculate the sizes of the carbon reser-

TABLE 1 Carbon densities and areal extents for 14 vegetation types

Vegetation type	Biomass ($kg\,C\,m^{-2}$)		Soil carbon ($kg\,C\,m^{-2}$)		Present area ($10^{12}\,m^2$)	18 kyr BP (−130 m) (% change)	18 kyr BP (−100 m) (% change)	$2\times CO_2$ (+2 m) (% change)

Global (Gt C)	748	834	1,143	1,313	132	$152\times10^{12}\,m^2$	$148\times10^{12}\,m^2$	$132\times10^{12}\,m^2$

The 14 simulated types are listed in column 1. They are: (1) tropical rain forest, (2) drought-deciduous woodland, (3) savanna, (4) arid grassland and shrubland, (5) desert, (6) mesic grassland, (7) Mediterranean forest and woodland, (8) cold-deciduous broad-leaved forest and woodland, (9) cold-deciduous needle-leaved forest and woodland, (10) evergreen needle-leaved forest and woodland, (11) tundra, (12) polar desert and ice, (13) temperate evergreen seasonal broad-leaved forest, (14) drought-deciduous and drought-seasonal broad-leaved forest. Carbon densities (columns 2–5) are based on published figures. They are constant for all climates. Areal extents of the 14 vegetation types (column 6) were bioclimatically simulated using observed climatology[4]. Simulated changes in areal extents (columns 7–9) are expressed as a percentage of present-day area (excluding Antarctica).

* Soil carbon is estimated directly from climate and averaged over the area of each vegetation type simulated from observed climate.

voirs in vegetation and soils at 18 kyr, for $2\times CO_2$ and for the present climate. Biomass estimates for vegetation types are taken from Whittaker and Likens[15] as well as from Olson *et al.*[16]. Soil carbon densities for their associated soils types are obtained by combining estimates of Ajtay *et al.*[17] and Schlesinger[18]. These carbon densities are geographic extrapolations of field measurements. The distribution of soil carbon densities is also estimated directly from climate using Post *et al.*'s superposition of isolines of soil carbon densities on the Holdridge climate space[19].

Over 75% and 60% of the present vegetated landscape was altered by the 18 kyr BP and $2\times CO_2$ simulated climates respectively. During the 18 kyr BP simulation, land temperatures dropped ~4.4 °C in the Southern Hemisphere and 8.5 °C in the Northern Hemisphere. Although the global landscape was more arid, eastern and southern coasts as well as present arid regions were wetter than today. The 100- and 130-m drop in sea level increased the land area by 12% and 15%. Regions of extreme climates (deserts, tropical rainforests and ice) show greatest sensitivity to climate change.

In this study, the biospheric carbon changes only because the distribution of vegetation types changes. The dynamics involved in both the change in the distribution of vegetation and changes in carbon density in response to changing climate are not considered. This analysis is a comparison of static snapshots of potential vegetation existing for today's, for the 18 kyr BP and for a $2\times CO_2$, climate.

Table 1 lists carbon densities for the 14 vegetation types (columns 2–5) as well as their present land areas (column 6) and percentage change in their areas associated with perturbed climates. (Numbers in the discussion refer to Olson *et al.*[16] and Post *et al.*[19] unless otherwise stated.) During the 18 kyr BP (−130 m) simulation, the advance of ice sheets claimed $25\times10^{12}\,m^2$ of present land, significantly reducing the extent of boreal vegetation. The areas of needle-leaved boreal forests (types 9 and 10) were reduced by 17% despite a 5% expansion on newly emerged land. The descent of the ice sheets and other effects of unfavourable climate as well as sea-level changes reduce the carbon stored in the 18 kyr BP boreal forests (type 9 and 10) by 80 Gt (30 Gt as biomass carbon and 50 Gt as soil carbon).

During the 18 kyr BP simulation, a large conversion of carbon occurred in the present land area of the equatorial region and in the Southern Hemisphere. Temperate and tropical broad-leaved forests (types 7, 8, 1, and 13) expanded into the cooler and wetter subtropical regions displacing subtropical broad-leaved forests and savannas (types 2, 14 and 3) which exist in climates having more strongly seasonal precipitation. The areal expansion of the less drought-seasonal forests (types 7, 8, 1 and 13) on existing and new land increases their carbon storage by 256 Gt, which is about equally divided between biomass and soil and also equally divided between new and existing land. The areas of the more drought-seasonal vegetation (types 2, 14 and 6) were reduced by 57% shrinking their carbon pool by 136 Gt (57 Gt carbon in biomass and 79 Gt as soil carbon).

Because of increased precipitation in arid regions during the 18 kyr BP simulations the area of deserts is reduced by 91%. Although 18 kyr BP desert decreases by $12\times10^{12}\,m^2$, this large area reduction represents only a 45 Gt decrease in the desert carbon pool—almost entirely as soil carbon.

Although the simulated biosphere responds dramatically to 18 kyr BP changes in climate, large regional changes in carbon reservoirs and changes in soil and biomass carbon offset one another in the global carbon budget. Global estimates of changes in carbon reservoirs from present to perturbed climates are listed in Table 2. Estimates of carbon-reservoir changes in Table 2 are broken into those effected by changes in both climate and sea level and those associated with changes in climate only. For 18 kyr BP climate with a 130 m drop in sea level, the 6% (43 Gt) gain in biomass carbon is offset by the 4% (43 Gt) decline in the soil carbon pool. Net change for the amount of carbon held in the 18 kyr BP (−130 m) biosphere is approximately zero. Like the changes in the biomass and soil reservoir, the changes in the global carbon reservoir associated with climate are also compensated by the effects of sea-level change on the biosphere. The direct effects of unfavourable 18 kyr BP climate reduce biomass carbon by 7% and soil carbon by 13%. This 200-Gt reduction of terrestrial biospheric carbon is offset by the development of vegetation and soil on new land. The $20\times10^{12}\,m^2$ of newly emerged land (Table 1) increases the carbon in the present terrestrial biomass by 13% and soil carbon by 9%. The amount and location of emerged land can account for a large increase in biospheric carbon. In this experiment, the biospheric

* Reservoir changes brought about by direct climate effects only

carbon supported on new land is as great as the changes in the biospheric carbon resulting directly from climate.

Similar changes in biospheric carbon reservoirs occurred in the 18 kyr BP (−100 m) simulation but the changes were affected by the smaller increase in land area associated with the 100 m drop in sea level. Biomass carbon storage increases by 3% (25 Gt) relative to the present reservoir whereas soils lose 6% (65 Gt). The terrestrial biosphere in this experiment loses 40 Gt of carbon.

The land climate for the $2\times CO_2$ simulation is an average of 5.4 °C warmer and is 17.5 mm d^{-1} wetter than present climate. Areas of tropical rainforests increase by 75% (Table 1) increasing their biomass and soil carbon reservoirs by 215 Gt and 130 Gt of carbon respectively. Desert (type 5) and semi-desert (type 4) regions are reduced by 60% and 20%, reducing the carbon stored in arid lands by 75 Gt. Cold-deciduous broad-leaved (type 8) forests expand northward in the Northern Hemisphere in the warmer, wetter $2\times CO_2$ climate adding 50 Gt carbon to their soil reservoirs and 60 Gt to their biomass. Areal decrease of boreal evergreen needleleaved forests (type 10) and tundra (type 11) reduces their soil carbon pool by 145 Gt.

The global terrestrial biosphere responds to the $2\times CO_2$ climate with a 31% increase in biomass a 1% increase in soil carbon. This 235-Gt carbon expansion of the terrestrial biosphere is due entirely to the change in climate (the sea level rises 2 m).

Although the spatial rearrangement of vegetation in response to perturbed climates is significant, the magnitude and direction of the net change in carbon storage remain unclear. Many caveats must accompany the resulting global carbon budgets. (1) At present, only 77% of the observed vegetated landscape can be replicated because we do not know how to express climate to define best the structural/functional attributes of vegetation. In addition, the secondary effects of soils, topography, humans and other environmental factors on the vegetation distribution are not accounted for in this study. Because misclassification of vegetation most often occurs between climatically similar vegetation types having similar carbon-storage attributes, the study's results are not highly sensitive to small errors in classification. Results are most sensitive to misclassifications in areas having a strong gradient in carbon density (for example, along a north-south transect of soil through ice, tundra and boreal forests). (2) We assume relationships now existing between climate classes and vegetation types hold for perturbed climates. In fact vegetation types existing under perturbed climates may differ in structure and function from those existing today. We also assume that vegetation is in equilibrium with climate — a condition which is never entirely met in a constantly changing climate. The assumption of steady state becomes less correct for the more slowly changing soil-carbon reservoir over what is believed to be the relatively short time period of an approaching $2\times CO_2$ climate. (3) The estimation and extrapolation of carbon densities for the geographically extensive and diverse vegetation types requires more field measurements than are presently available. Sensitivity of global terrestrial carbon storage to small errors in the carbon-storage description (Table 1) increases with the area of the vegetation type. Such errors are likely to increase with the density of carbon storage, with increasing percentage of storage in the soil (where carbon density is more difficult to measure), with diversity of carbon storage within vegetation type (making extrapolation of field measurements difficult) and inversely with the frequency of the field sampling of carbon density. The discrepancies between the minimum terrestrial carbon storage[16,19] shown in Table 2 and the maximum values[15,17,18] for a single-climate scenario are generally more than double the storage differences between climate scenarios. (4) Uncertainties and errors in GCM simulations, especially of precipitation affect the distribution of vegetation and terrestrial carbon. (5) At the GCM level of generalization and structural homogenization of vegetation types, issues of CO_2 fertilization and the functional differences of C_3 and C_4 plants cannot be addressed. (6) The 100-m and 130-m drops in sea level in the 18 kyr BP simulations are responsible for a 40-Gt difference in the amount of carbon stored in the biosphere. (7) Estimates of the changes in the net global biospheric carbon are obtained by summing large numbers often having opposite signs. Because there is a large margin of error in each component number, an accurate net change in the global terrestrial biosphere is difficult to obtain. Some generalizations, however, are possible.

In our study, both biomass and soil carbon pools during the 18 kyr BP (−130 m) simulation decreased by 200 Gt carbon on the present land area, or ~10% of the total present land reservoir. The decrease is countered by the substantial increase of carbon stored on the newly emerged land. The magnitude of this compensation is difficult to ascertain because of the uncertainties in the sea-level change and lack of understanding of the biosphere on the new landscape. By assuming a sea-level drop of 130 m and applying today's terrestrial carbon relationships, we obtain an increase in carbon storage of 200 Gt on new land, exactly compensating for the loss owing to unfavourable climate. Although our best estimate of the mass transfer of carbon between the biosphere and the atmosphere for the 18 kyr BP simulation is approximately zero, Tables 1 and 2 show possible biospheric changes ranging from an increase of 30 Gt carbon for −130 m (refs 16–18) to a decrease of 50 Gt carbon for the −100-m experiment[15,19]. Although biospheric changes do not dominate the 82-p.p.m. (165 Gt carbon) difference in atmospheric CO_2 between the Holocene and 18 kyr BP found in ice cores, their contribution may not be negligible because of uncertainties in calculating the components of large compensating factors in the biosphere–atmosphere carbon flux.

In our $2\times CO_2$ simulation, the change in sea level (+2 m) has a negligible effect on global land area. In this experiment, a terrestrial biosphere in equilibrium with a $2\times CO_2$ climate has an increased carbon storage ranging from 338 Gt (refs 15, 17, 18) to 245 Gt (refs 16, 19), or 169 p.p.m. to 122 p.p.m. This represents a potentially strong negative feedback on the atmospheric CO_2 increase.

In both cold and warm climates, the redistribution of vegetation results in carbon transfers from soil to biomass and from boreal to tropical regions. The present climate seems to be unique in its capacity to support such extensive carbon-rich boreal soils and such extensive carbon-poor arid lands.

These sensitivity experiments explore the influence the terrestrial biosphere might have had in the glacial–interglacial changes of atmospheric CO_2 as well as the possible carbon-storage role in a $2\times CO_2$ climate. We hope that this research can provide a framework to analyse and extrapolate terrestrial response to global climate changes. □

BLACK smoker chimneys are hollow spires formed by mineral deposition at sea-floor hydrothermal vent sites. They grow in two stages: formation of a sulphate-dominated wall (stage I), followed by precipitation of sulphide minerals on the inner side, and in pore spaces, of the wall (stage II)[1,2]. Here we present the results of an *in situ* 46-day experiment which allows direct observation of stage I growth processes by monitoring wall and fluid temperatures. The position and thickness of stage I chimney walls can change on short timescales, and are controlled by the dynamics of fluid flow both during[3] and after initial wall emplacement. The temperature in the main flow remained stable at 353±2 °C throughout the experiment, including the period during which the chimney wall was constructed. Six thermocouples, however, recorded maximum temperatures between 365 and 405 °C, which are significantly higher than most exit temperatures documented previously[4]. These latter observations bear on the question of the maximum temperatures attainable in sea-floor hydrothermal systems (refs 4–9, J. R. Delaney, manuscript in preparation).

In July 1988 an instrument equipped with an array of thermocouples housed within a test collar was deployed in the Endeavour hydrothermal vent field (47° 57′ N) on the Juan de Fuca Ridge[10,11]. The collar (Fig. 1*a*) was set over the opening of a black smoker vent and remained in place for 46 days. Temperatures (Fig. 2) were recorded every 2 min by 10 thermocouples inside the collar, 2 thermocouples outside the collar, and a platinum resistance temperature device (RTD) on the instrument platform, which was moored 1 m from the collar. The presence of the collar and thermocouples probably influenced fluid flow and mineral deposition to some extent, but some disturbance is unavoidable.

During the first 52 hours of the experiment, before chimney growth, the thermal structure of the hydrothermal plume was documented. Temperatures at TC02 (thermocouple 2), TC03 and TC09 increased rapidly to, and remained stable at, 353± 2 °C. Temperatures increased more slowly to maxima of 353± 2 °C at TC05, TC06 and TC11, 365 °C at TC08, 375 °C at TC10, 381 °C at TC07, and 405 °C at TC04. The three highest temperatures are on the boiling curve (375 °C) or in the two-phase region for a seawater-salinity fluid at 220 bars[6,12]. Excursions to ≥375 °C lasted for 90 min at TC04, 42 min at TC07 and 4 min at TC10, and were generally coincident but not simultaneous. In 1984 temperatures of 370–>400 °C and of >400 °C were measured at this site (Endeavour hydrothermal field; refs 6, 7, J. R. Delaney, manuscript in preparation) but their reliability has been disputed because these values were not reproduced on subsequent visits (temperatures were lower, but the same individual vents were not occupied) (ref. 4, J. R. Delaney, manuscript in preparation). In 1988 a temperature of 375 °C was measured 2 km to the north (ref. 5, J. R. Delaney, manuscript in preparation). Nearly all other published exit temperatures are <350±5 °C (ref. 4), including the temperature of the main flow measured in this experiment. Experimental reproduction of hydrothermal fluid compositions, however, has only been accomplished at temperatures >385 °C (refs 8, 9). Our high-temperature measurements seem to be reliable because they were all made adjacent to one another (Fig. 1*a*), and all thermocouples recorded temperatures within 2–4 °C of one another (within the error limits, ±2 °C) during deployment and recovery, and seem to have performed consistently throughout all other portions of the experiment. On the other hand, thermocouple TC02, only 4 cm from TC04, recorded a stable temperature of 353±2 °C for the duration of the experiment, including the period during which TC04 recorded 405 °C, and the thermocouples that measured anomalously high values did not record stable temperatures or temperatures similar to one another (Fig. 1*b*). The simplest explanation that accounts for all measurements is that there were two sources, one that was very stable at 353 °C, and a second, hotter source which was responsible for the >355 °C temperatures (J. R. Delaney, manuscript in preparation).

TABLE 1 Pressure difference across chimney wall

Diameter (m)	Volume flow rate ($m^3 s^{-1}$)	Pressure difference (Pa)
0.016	0.00039	0
	0.00069	6,700
0.02	0.00039	−2,200
	0.00069	0
0.025	0.00039	−2,900
	0.00069	−2,200

Pressure differences calculated using equation (2), using $y=1$ m and $f=0.04$ (ref. 3); densities for 2 °C sea water and 350 °C hydrothermal fluid are 1,003 and 674 kg m^{-3} (ref. 12), respectively.

The anomalously high temperatures were recorded only during a short time following emplacement of the collar. Within 7 hours, temperatures at TC04, TC07, TC08 and TC10 became relatively stable at 369, 361, 358 and 357 °C respectively, and drifted to 363, 356, 354 and 354 °C over the next 45 hours. During this time all other thermocouples in the collar measured stable temperatures of 353±2 °C (Fig. 1*c*, Fig. 2*a*). The initial rapid increases to 353±2 °C at TC02, TC03 and TC09 indicate that hot fluid was directed against one side of the test collar (Fig. 1). Progressive increases in temperatures at the other thermocouples to >350 °C probably reflect decreases in leakage of sea water into the collar as mineral precipitation at the collar base sealed openings.

During the third day of the experiment, temperatures at all thermocouples except TC02 and TC03 began to change rapidly (Fig. 2*b*), indicating the sudden onset of seawater entrainment over the top of the collar (Fig. 1*d*). The cause of entrainment is unclear but possibilities include development of an instability in the turbulent plume, or a sudden decrease in flow rate. The data show that once sea water was entrained, a barrier formed rapidly (in 6–12 h; Fig. 2*b*), isolating TC06, TC07 and TC11 from the fluid. Over the following 3.5 days, temperatures at TC06, TC07, TC10 and TC11 decreased to <106 °C, and temperatures at TC05, TC04, TC09 and TC08 fluctuated rapidly, consistent with being in zones of mixing. TC03 also showed minor fluctuations, at one point recording a temperature of 372 °C; TC05 recorded 372 °C 30 min before the TC03 measurement. Throughout this time, and during wall emplacement, TC02 remained stable at 353 ± 2 °C. After 3.5 days, temperatures at each thermocouple became relatively constant. TC08 recorded a temperature of 309 °C, consistent with being located in the newly formed chimney wall; TC09 and TC04 recorded temperatures of 342 and 343 °C, indicating that they were in or against the inner side of the chimney wall, and TC05 and TC03 recorded stable temperatures of 353 ± 2 °C, indicative of being in rapidly moving high-temperature fluid.

During the remaining 40 days of the experiment temperatures at TC06, TC07, TC10 and TC11 decreased to ambient temperatures (Fig. 2*a*) as the wall became impermeable to leakage of hydrothermal fluid. Temperatures at TC02 and TC03 remained stable at 353 ± 2 °C, and temperatures at TC04, TC08, TC05 and TC09 decreased to 21, 67, 134 and 283 °C, respectively. On recovery, TC04 was outside the wall, TC08 was against the outer wall, and TC05 and TC09 were embedded in the wall (Fig. 1*h*). The final locations of these thermocouples and the recorded decreases in temperature with time are most easily accounted for by inward thickening of the wall coupled with

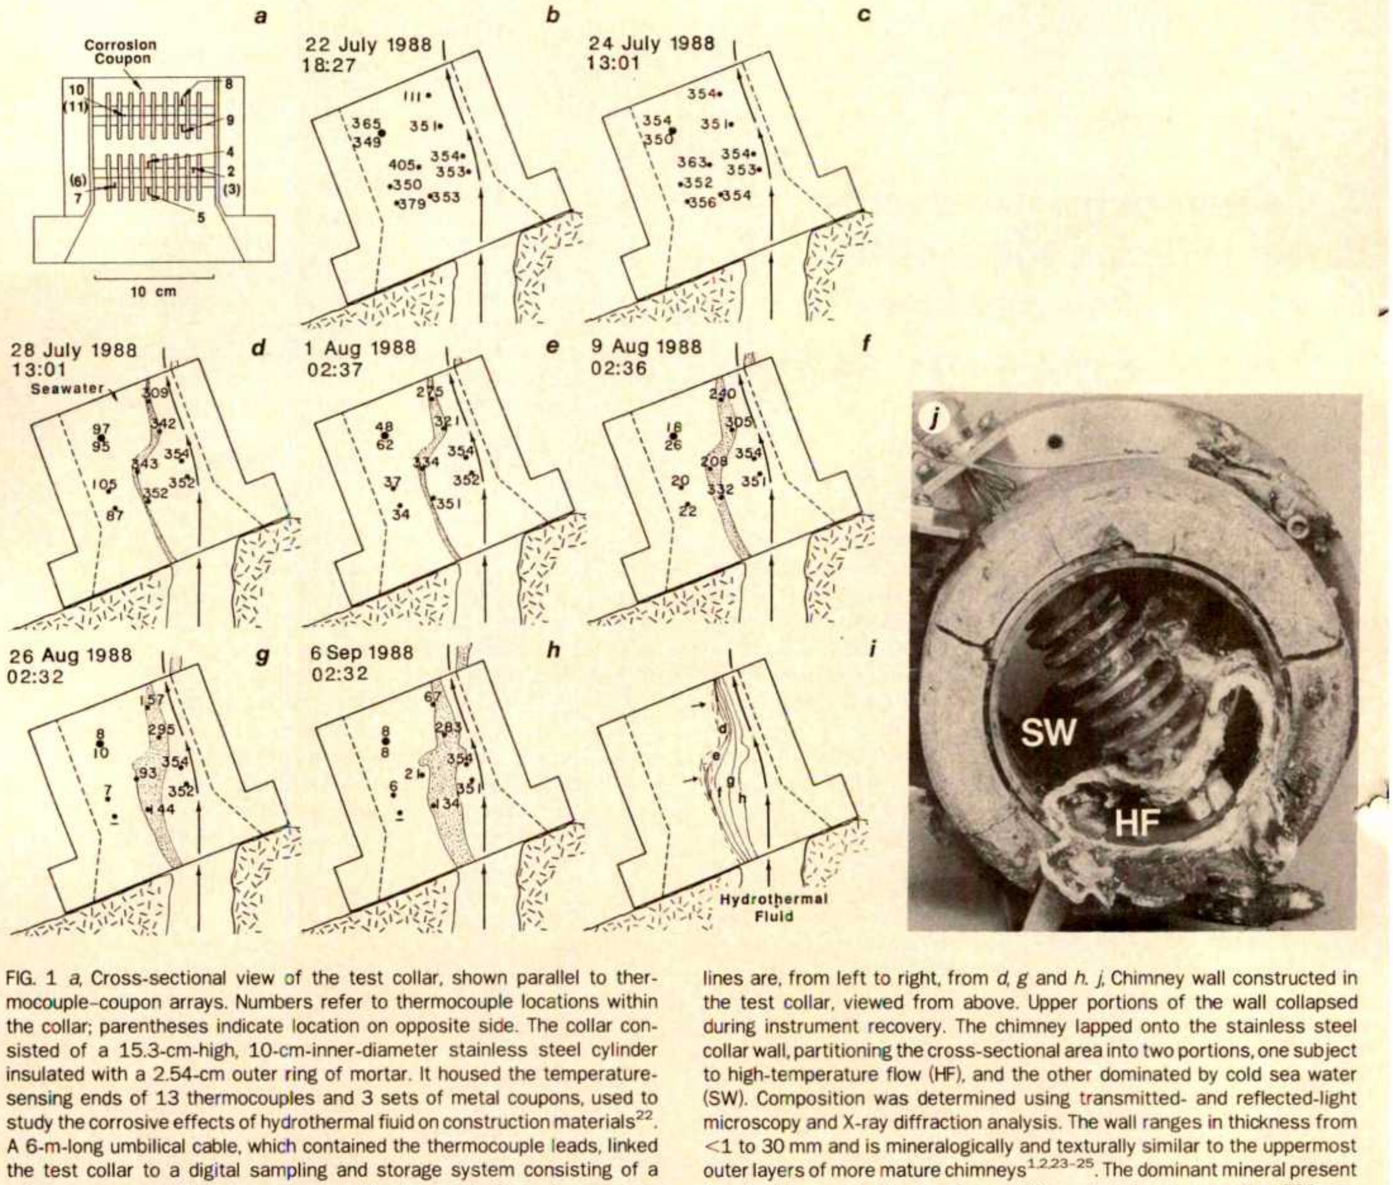

FIG. 1 *a*, Cross-sectional view of the test collar, shown parallel to thermocouple–coupon arrays. Numbers refer to thermocouple locations within the collar; parentheses indicate location on opposite side. The collar consisted of a 15.3-cm-high, 10-cm-inner-diameter stainless steel cylinder insulated with a 2.54-cm outer ring of mortar. It housed the temperature-sensing ends of 13 thermocouples and 3 sets of metal coupons, used to study the corrosive effects of hydrothermal fluid on construction materials[22]. A 6-m-long umbilical cable, which contained the thermocouple leads, linked the test collar to a digital sampling and storage system consisting of a microprocessor, solid-state memory and battery pack. Corrosion coupons exposed to fluids included nickel and titanium alloys, and stainless steel. Only stainless steel coupons exhibited corrosion. *b*–*g*, Cross-sectional view of collar showing measured temperatures and inferred wall positions (stippled) during the experiment. The 20° angle of the test collar from vertical represents the inferred orientation during the experiment, based on observations of flow during deployment, and on the 20° angle of the uppermost chimney wall to the test collar on recovery. *h*, Temperatures recorded before instrument recovery, and location of the wall inside the collar on recovery. *i*, Location of the inner (solid lines) and outer (dashed lines) chimney wall as a function of time; wall positions are taken from *d*–*h*, and are labelled as such. Arrows indicate places on outer wall subject to dissolution. Dashed lines are, from left to right, from *d*, *g* and *h*. *j*, Chimney wall constructed in the test collar, viewed from above. Upper portions of the wall collapsed during instrument recovery. The chimney lapped onto the stainless steel collar wall, partitioning the cross-sectional area into two portions, one subject to high-temperature flow (HF), and the other dominated by cold sea water (SW). Composition was determined using transmitted- and reflected-light microscopy and X-ray diffraction analysis. The wall ranges in thickness from <1 to 30 mm and is mineralogically and texturally similar to the uppermost outer layers of more mature chimneys[1,2,23–25]. The dominant mineral present is anhydrite, ranging in size from <10 μm to >1 mm, averaging 500 μm. Fine grains (<5–20 μm) of pyrrhotite, pyrite, chalcopyrite and sphalerite or wurtzite intergrown with and included in anhydrite are present in small amounts (<5–10%). Minerals do not exhibit any signs of replacement. A thin (<1 mm) partially continuous layer of chalcopyrite is present on the inner side of the wall. At some locations, ridges of anhydrite project into the open channel. X-ray diffraction analyses of the thickest portion of the wall indicate the presence of caminite (magnesium hydroxysulphate hydrate). The only other reported occurrence of caminite, which was also intergrown with anhydrite, was in the outer portion of a black smoker chimney wall from 21° N on the East Pacific Rise[26–28].

some dissolution and removal of the outer wall at TC04 and TC08. Recorded temperatures and inferred wall positions for six different times are displayed in Fig. 1.

The experiment allowed the first direct observation of a very young chimney wall. The wall that grew up through the collar is composed dominantly of anhydrite (Fig. 1*j*). Only a very thin (<1 mm) layer of chalcopyrite is present against the inner side of the wall, and the few sulphide grains intergrown with and included in anhydrite do not exhibit any signs of replacement. The time-series records indicate that the wall was emplaced on a timescale of days, consistent with previous observations[2,13], and that it then thickened inward by as much as 2.5 cm over a time interval of weeks (Fig. 1*i*). The lack of replacement of earlier formed minerals, and presence of only minor amounts of chalcopyrite lining the innermost (youngest) chimney wall, indicate that stage I growth prevailed. Inward growth was dominated by anhydrite deposition, which requires the presence of sulphate, a component available in sea water but not in hydrothermal fluid[14]. If sulphate is supplied by the inward advection of sea water, then the rate of thickening is controlled by the magnitude of the pressure gradient across the wall, and by permeability K as expressed by Darcy's law

$$u = -\frac{K}{\eta}\frac{P_i - P_o}{dx} \qquad (1)$$

where u is advection rate, η is viscosity, dx is the width of the porous medium, and P_i and P_o are pressure on the inner and outer sides of the wall[15]. Inward growth by deposition of anhydrite should cease when P_i becomes equal to or greater than P_o.

The magnitude of the pressure difference required to produce the observed thickening of the wall can be estimated by considering (1) the flux of sulphate necessary to account for deposition of a 0.025-m-thick wall of anhydrite (molar volume 4.6×10^{-5} m^3 mol^{-1}; ref. 16) in 40 days, which is 1.6×10^{-4} mol m^{-2} s^{-1}, and (2) the advection rate of sulphate (concentration in sea water of 28 mol m^{-3}; ref. 17) necessary to provide this flux, 5.7×10^{-6} m s^{-1}. This advection rate could be generated by a pressure difference of −2,253 Pa across a 0.025-m-thick wall (calculated using equation (1)), assuming an average viscosity of hot seawater-salinity fluid of 5×10^{-4} Pa s (ref. 18), and a permeability similar to that of sandstone ($10^{-13.5}$ m^2; ref. 14). Conditions under which such a pressure difference would exist can be evaluated using a method that considers the fluid dynamics of high-velocity flow inside the chimney channel[3]. The pressure difference inside a chimney of constant diameter d can be calculated by summing the buoyancy force with a friction loss term

$$P_i - P_o = (\rho_i - \rho_o)gy + \frac{8f\rho_i Q^2}{\pi^2 d^5}\,y \qquad (2)$$

where ρ is fluid density, y is depth in the channel, f is a friction factor, and Q is volume flow rate[3]. Calculated pressure differences at a depth of 1 m from the top of the chimney as functions of Q and d are given in Table 1. The value of d that corresponds to a pressure difference of zero for a given constant flow rate is termed the 'stable' chimney diameter[3]. A pressure difference of the order of −2,200 Pa at a depth of 1 m in the channel, which would permit inward thickening, could result either from a decrease in volume flow rate after initial emplacement at a stable diameter[3], or from emplacement of the wall at a diameter larger than this. The larger diameter could occur if wall emplacement mimics the outer bound of the plume which expands above the chimney orifice[19]. In either case inward growth would cease when a stable diameter for the existing volume flow rate Q is achieved.

The idea of a stable diameter can also be used to explain why the chimney wall grew within the test collar instead of on top of it. Formation of a chimney wall with a stable diameter of 10 cm would require an extremely high flow rate of 26 kg s^{-1} (0.0384 m^3 s^{-1}). Estimated mass flow rates from vigorous smokers at 21° N on the East Pacific Rise are significantly less, of the order of 1.5 kg s^{-1} (ref. 19). The wall formed within the test collar had a hydraulic radius (cross-sectional area/perimeter) of 0.005 m, equivalent to a circular diameter of 0.02 m, which corresponds to a more reasonable flow rate of 0.5 kg s^{-1} (0.00069 m^3 s^{-1}). The experiment indicates that the orifice diameter and position and thickness of the anhydrite-dominated stage I wall are not just a result of initial mixing between the plume and ambient sea water[3], but are also controlled by the dynamics of fluid flow in the chimney channel after wall emplacement.

This experiment demonstrates that *in situ* monitoring of vent phenomena is possible. The extent to which the solid collar wall and coupons influence mixing and/or fluid flow in the chimney

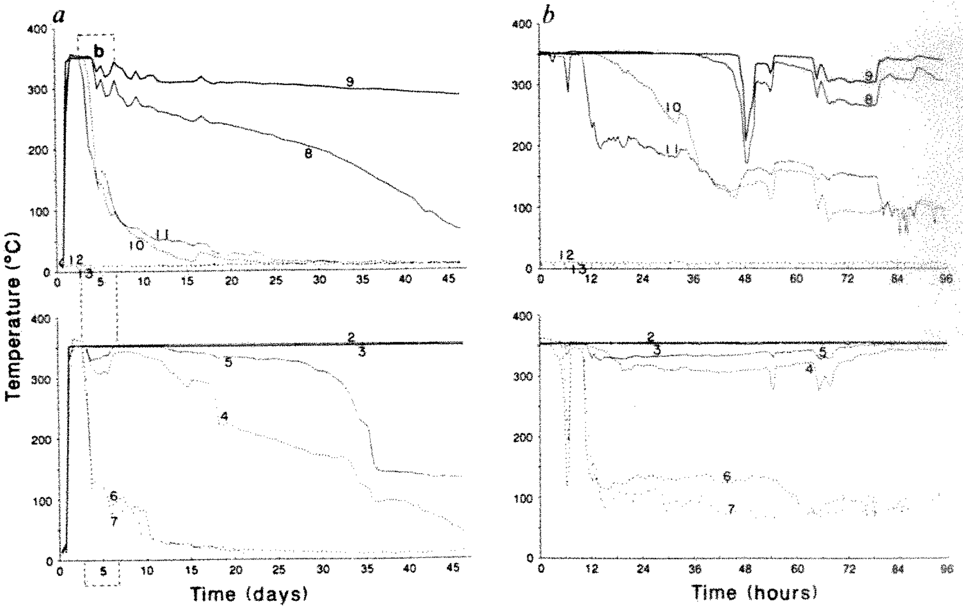

FIG. 2 *a*, Average temperatures for 12-h intervals measured over 46 days. Maximum temperatures recorded by TC03, TC04, TC05, TC07, TC08 and TC10 were 372, 405, 372, 381, 365 and 375 °C respectively. The remaining thermocouples in the test collar recorded maximum temperatures of 353 ± 2 °C, and TC02 recorded 353 ± 2 °C for the duration of the experiment. *b*, Average temperatures for 30-min intervals measured during the initial wall-building stage. Numbers refer to thermocouples. Immediately outside the test collar, temperatures varied between 6 and 16 °C for the duration of the experiment (TC12 and TC13), and at the platform containing the sampling and storage system the temperature varied from 2.5 to 3.2 °C. Temperatures were measured using ungrounded type K (chromel–alumel) thermocouples with error limits of ±2.2 °C up to 277 °C and ±0.75% for temperatures between 277 and 1,260 °C. The electronics package and reference RTD were moored 1 m away from the active vent, housed in a 1.77-cm-thick PVC case located at the end of a 6-m-long cable. Calibration before deployment consisted of placing the electrical-junction box in a thermostatically controlled freezer and the test collar and thermocouples in a vessel of boiling water. During the 24-hour test the RTD and all thermocouples performed within the expected error limits. Recalibration after the experiment was not done because it would have required dissolution of the chimney wall.

channel can be minimized in future experiments by modifying the instrument—for example, by eliminating the coupons and suspending a set of thermocouples above the collar. Longer experiments can be coupled with time-lapse camera studies[20,21] so that wall position and upward growth rates can be discerned. This technique can be used to investigate transport and chemical reaction across steep thermal and chemical gradients, the time-scale and long-term stability of sea-floor vent structures, and the stability and range of temperatures exhibited in hydrothermal systems. ☐

Eclogitic diamonds of Proterozoic age from Cretaceous kimberlites

S. H. Richardson*, A. J. Erlank*, J. W. Harris† & S. R. Hart‡

* Department of Geochemistry, University of Cape Town, Rondebosch 7700, South Africa
† Department of Geology and Applied Geology, University of Glasgow, Glasgow G12 8QQ, UK
‡ Department of Geology and Geophysics, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543, USA

DIAMONDS with eclogitic inclusions ('eclogitic diamonds') from the Premier kimberlite and Argyle lamproite were previously shown to be of Proterozoic age[1–3] and distinct in origin from peridotitic diamonds of Archaean age[4] and deep-continental-mantle (tectospheric[5]) provenance. The Premier and Argyle host rocks are themselves of Proterozoic age, suggesting a link between eclogitic diamond formation and kimberlite or lamproite magmatism[1]. Here we test this link by examining eclogitic diamonds from younger southern African kimberlites. Eclogitic garnet and clinopyroxene inclusions in Orapa and Finsch diamonds yield Sm–Nd isochron ages of 990 and 1,580 Myr respectively, compared with host kimberlite emplacement ages of ~100 Myr. These eclogitic diamond ages are again Proterozoic, and distinct from the ~3,200-Myr age of Finsch peridotitic diamonds[4]. Thus peridotitic and eclogitic diamonds from the same locality are evidently both xenocrysts, having been stored in the deep continental mantle beneath the Kaapvaal craton for extended periods before being sampled by kimberlite. Such mantle storage may not be detected by the ^{40}Ar–^{39}Ar laser-probe dating technique as applied to Premier diamonds[2,3].

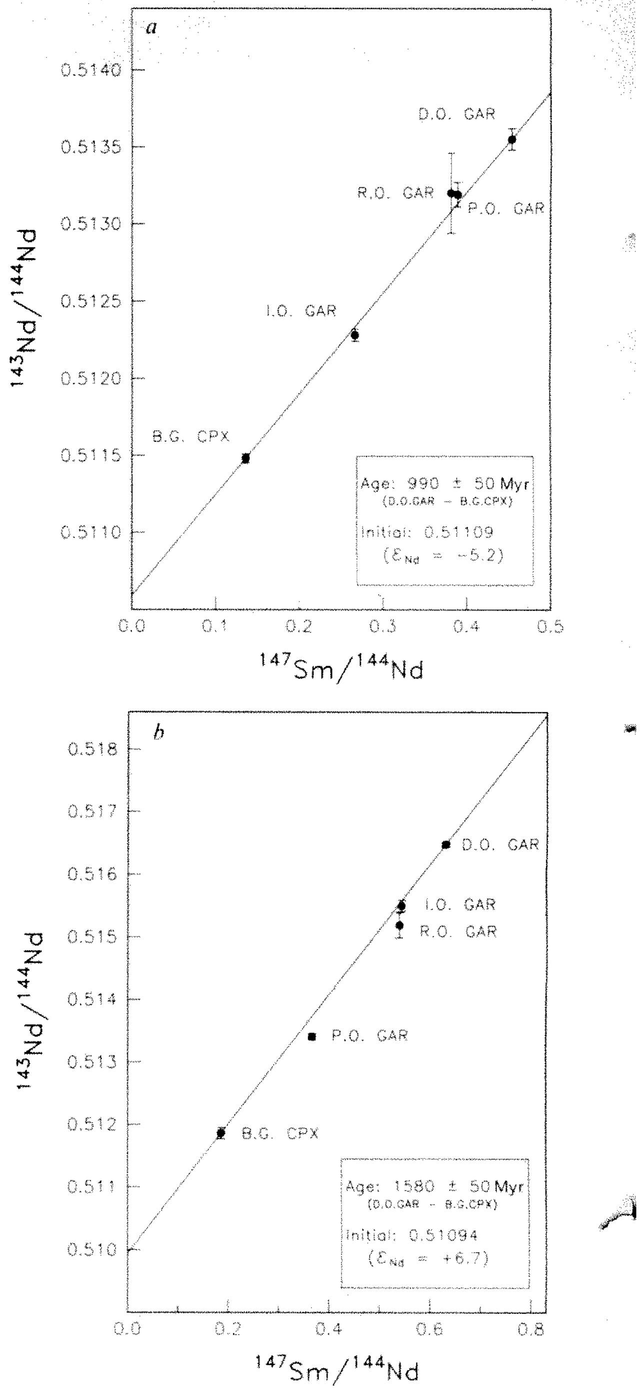

FIG. 1 Sm–Nd isochron diagrams for eclogitic garnet and clinopyroxene inclusions in Orapa (*a*) and Finsch (*b*) diamonds with sample abbreviations as in Table 1. The ages are calculated for the deep-orange garnet/bluish-green clinopyroxene pairs, using $\lambda_{Sm} = 6.54 \times 10^{-12}$ yr^{-1}, with assigned errors derived from maximum and minimum slopes allowed by $2\sigma_{mean}$ measurement errors.

The Premier kimberlite, where the ^{40}Ar–^{39}Ar laser-probe dating technique was first tested on eclogitic diamond inclusions[2,3], is an unusual case in which similar diamond crystallization and kimberlite emplacement ages cannot be resolved by current dating techniques. Nevertheless, these diamonds have nitrogen aggregation characteristics requiring a minimum 1–10 Myr period of mantle storage (within the errors of the age determinations) and implying a xenocrystal relationship to the host kimberlite itself[1]. R. Burgess (personal communication) has recently

Concentrations in p.p.m. (μg per g), after correction for minimum applicable blanks: Rb, 3 pg; Sr, 4 pg; Sm, 0.6 pg; Nd, 1.5 pg. Estimated analytical uncertainties in concentrations (ignoring small-sample weighing errors) are indicated by the number of significant digits. Present-day $^{87}Sr/^{86}Sr$ and $^{143}Nd/^{144}Nd$ ratios are normalized to 0.70800 and 0.51264 for standards E & A $SrCO_3$ and BCR-1, respectively. In-run precision is indicated by the errors ($2\sigma_{mean}$) in the least-significant digits given in parentheses. Initial ratios (denoted by subscript i) calculated for Orapa and Finsch diamond crystallization ages of 990 and 1,580 Myr, respectively, using decay constants $\lambda_{Rb} = 1.42 \times 10^{-11}$ yr^{-1} and $\lambda_{Sm} = 6.54 \times 10^{-12}$ yr^{-1}. Inclusion-bearing diamonds were selected from the −6 +5 diamond sieve fraction (1.8–2.2 mm diameter) of general mine production.

* Orapa composites: ~160 deep-orange garnets (d.o. gar), 110 intermediate-orange garnets (i.o. gar), 60 pale-orange garnets (p.o. gar) and 80 reddish-orange garnets (r.o. gar) (average weight 16 μg); ~220 bluish-green clinopyroxenes (b.g. cpx) (average weight 8 μg).

† Finsch composites: ~150 d.o. gar, 80 i.o. gar, 130 p.o. gar and 60 r.o. gar (average weight 11 μg); ~90 b.g. cpx (average weight 5 μg).

‡ Single large d.o. gar successfully analysed for Rb–Sr only in 1985.

obtained ^{40}Ar–^{39}Ar ages for eclogitic clinopyroxene inclusions in Orapa diamonds approaching that of the host kimberlite. Whereas diamond encapsulation precludes diffusive exchange of elemental species between inclusions that are not touching, these species are able to diffuse through the inclusion minerals themselves at mantle temperatures and pressures. Further, although cations such as Sm, Nd, Rb, Sr and K remain within the crystal structures of the inclusion minerals, the noble gas Ar seems to be able to accumulate at inclusion/diamond interfaces, effectively separating radiogenic Ar from the parent K and resetting the K–Ar clock within clinopyroxene until removal to the surface. This technique may therefore give ages indicative more of the kimberlite emplacement event than of the diamond crystallization event.

The Orapa kimberlite is located in the Archaean Limpopo Mobile Belt in northeastern Botswana. A zircon U–Pb age of 93 Myr provides the most reliable estimate of emplacement age[6], which is Cretaceous and consistent with the preservation of crater facies deposits[7]. The Orapa locality was chosen for this study because of its relative abundance of diamonds containing eclogitic inclusions. The eclogitic and lesser websteritic assemblages of orange garnet, bluish-green clinopyroxene, sulphides and orthopyroxene together comprise >85% of inclusions in Orapa diamonds[8].

The Finsch kimberlite is located in the southwestern interior of the Archaean Kaapvaal craton. In the absence of zircons, a phlogopite Rb–Sr age of 118 Myr provides the most reliable estimate of emplacement age[9]. The Finsch locality was chosen because of the Archaean age of its dominant peridotitic-inclusion-bearing diamonds[4] and because of a parallel study of individual large diamonds containing eclogitic garnet inclusions, by Smith *et al.* (ref. 10 and manuscript in preparation). The eclogitic assemblage of orange garnet, bluish-green clinopyroxene and sulphides accounts for <2% of inclusions in Finsch diamonds[11], so extensive sorting was required to collect sufficient material for analysis.

Small-sample preparation techniques and mass spectrometric facilities for the determination of Sm, Nd, Rb and Sr concentrations and isotope ratios (Table 1) were the same as those used in ref. 1. Here, further categories of garnet were identified on the basis of subtle variations in colour. Major-element analyses of single specimens of each of the resultant deep-, intermediate-, pale- and reddish-orange garnet and bluish-green clinopyroxene categories are reported in Table 2. By comparison with world-wide occurrences[12], these are all clearly eclogitic with the possible exception of the Orapa reddish-orange garnet, which displays a websteritic character[8]. This colour characterization is used for convenience in separating components with a spread of Sm/Nd ratios between those of deep-orange garnet and bluish-green clinopyroxene, which constitute a cogenetic pair in rare bimineralic-inclusion-bearing diamonds (not used in this study)[1]. Otherwise, we used the same analytical strategies and precautions with respect to composites as in ref. 1. In particular, Rb/Sr ratios for both garnet and clinopyroxene are extremely low, resulting in barely significant increases in $^{87}Sr/^{86}Sr$ ratio on a 1,000-Myr timescale. Thus, $^{87}Sr/^{86}Sr$ ratios can be used to examine the cogeneticity of garnet and clinopyroxene inclusions from separate diamonds, which have been paired to derive ages from Sm–Nd isochrons.

The Orapa deep-orange garnet/clinopyroxene pair defines a two-point Sm–Nd isochron age of 990 ± 50 Myr (Fig. 1*a*), where the error is derived from the maximum and minimum slopes allowed by $2\sigma_{mean}$ measurement errors (Table 1). The intermediate-, pale- and reddish-orange garnets with intermediate Sm/Nd ratios also lie on the isochron, within the errors. Regression analysis of the complete data set is not warranted, however, because the initial $^{87}Sr/^{86}Sr$ ratios of the garnets (0.7077–0.7105) are all higher than that of the clinopyroxene (0.7061) as also shown on a present-day Sr isotope mixing diagram (Fig. 2). Ideally, the deep-orange garnet and the clinopyroxene should have the same $^{87}Sr/^{86}Sr$ ratio if they are cogenetic (as in diamonds with bimineralic inclusions[1]) but the actual datum for this composite in Fig. 2 indicates that the colour categories are unreliable and/or were not well separated during sample preparation. The reddish-orange garnet has the highest $^{87}Sr/^{86}Sr$ ratio, making it the other obvious endmember component. Nevertheless, the shape of the Orapa data field in Fig. 2 rules out simple two-component mixing as an explanation for the linear relationship in Fig. 1*a*.

Similarly, the Finsch deep-orange garnet/clinopyroxene pair defines a two-point Sm–Nd isochron age of 1,580 ± 50 Myr (Fig. 1*b*). The intermediate-, pale- and reddish-orange garnets again have intermediate Sm/Nd ratios but the latter two lie well below the isochron. The initial $^{87}Sr/^{86}Sr$ ratios of the garnets (0.7050–0.7109), including that for a single large deep-orange garnet inclusion (F11 in Table 1), are again higher than that of the clinopyroxene (0.7046) but in this case the deep-orange garnet and clinopyroxene have reasonably similar values (Fig. 2). Again, the reddish-orange garnet has the highest $^{87}Sr/^{86}Sr$ ratio. Further, a single large Finsch eclogitic garnet inclusion analysed by Smith *et al.*[10] lies on the 1,580-Myr isochron in Fig. 1*b* (at 0.702, 0.51818(5)) albeit with a slightly lower $^{87}Sr/^{86}Sr$ ratio (0.7041).

The $^{87}Sr/^{86}Sr$ ratios of the different garnet composites indicate the presence of several different components in the eclogitic inclusion assemblage at both localities. The two extremes are

represented by the 'pure' deep-orange garnet/clinopyroxene pair and the reddish-orange garnet. Nevertheless, the Sm–Nd isotope data conform reasonably well to isochron relationships implying a more restricted range of initial $^{143}Nd/^{144}Nd$ ratios than the range of initial $^{87}Sr/^{86}Sr$ ratios in each case. This can be understood in terms of a trace-element-enriched (high Rb/Sr, low Sm/Nd) character for the precursor of the reddish-orange garnet, resulting in radiogenic initial $^{87}Sr/^{86}Sr$ and nonradiogenic initial $^{143}Nd/^{144}Nd$ ratios for such components. Thus, the isochron relationships in Fig. 1 seem to have age significance (rather than being mixed lines) and the corresponding initial $^{143}Nd/^{144}Nd$ ratios indicate a dominantly enriched precursor at Orapa ($\varepsilon_{Nd} = -5$; $\varepsilon_{Nd} = \{[(^{143}Nd/^{144}Nd)_{sample}/(^{143}Nd/^{144}Nd)_{bulk\ Earth}] - 1\} \times 10^4$) and a depleted precursor at Finsch ($\varepsilon_{Nd} = +7$). This difference is also reflected in the carbon isotopic composition of eclogitic diamonds which at Finsch have $\delta^{13}C$ values of −3 to −8‰ (ref. 13; $\delta^{13}C(‰) = [(^{13}C/^{12}C)_{sample}/(^{13}C/^{12}C)_{standard}] - 1$, PDB standard consistent with a depleted upper-mantle carbon source, and at Orapa values of −3 to −23‰ (P. Deines *et al.*, manuscript in preparation), which may indicate the involvement of recycled crustal carbon (M. B. Kirkley *et al.*, manuscript in preparation).

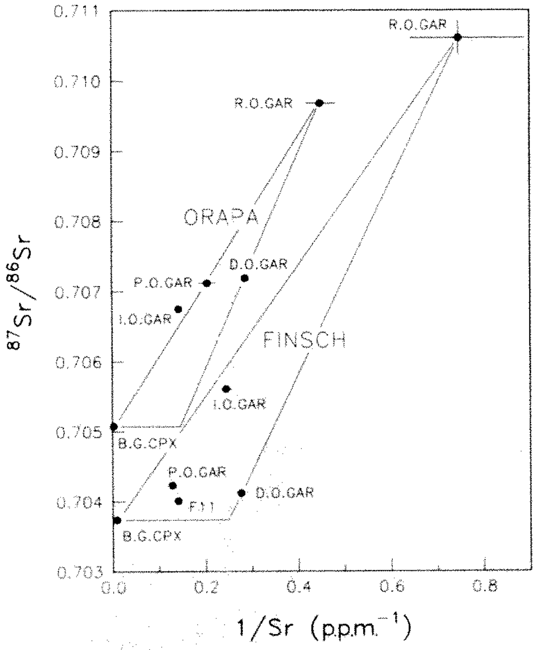

FIG. 2 Sr isotope mixing diagram with present-day $^{87}Sr/^{86}Sr$ plotted against reciprocal Sr concentration for eclogitic inclusions in Orapa and Finsch diamonds. Errors in Sr concentration are dominated by a nominal small-sample weighing error of ±0.05 mg. Mixing curves are straight lines and nominal mixing envelopes for Orapa and Finsch inclusion composites are indicated although no direct mixing of garnet and clinopyroxene is implied.

Thus there is clear evidence that eclogitic diamond formation involved at least two enriched components at Orapa and both depleted and enriched components at Finsch. Also, the precursor Nd and C isotope signatures of eclogitic diamonds from Finsch and Orapa resemble those from Premier and Argyle[1], respectively. In contrast to peridotitic diamond formation, which can be correlated with early Archaean komatiite magmatism and continental mantle stabilization[4], eclogitic diamond formation has yet to be correlated with regional tectonothermal events, although subduction is a distinct possibility. Further, the crystallization ages of peridotitic and eclogitic diamonds from Finsch differ by more than 1,500 Myr, and their precursors have contrasting enriched and depleted isotope signatures. The radiogenic Sr component evident in reddish-orange garnet inclusions in eclogitic diamonds may be derived from subducted crust and/or the enriched garnet harzburgite host assemblages of peridotitic diamonds stored in tectospheric mantle since the Archaean[4].

More generally, trace-element-depleted components (characterized by positive ε_{Nd} values) are derived from asthenospheric mantle (the source of mid-ocean-ridge basalts) whereas trace-element-enriched components (particularly those with negative ε_{Nd} values) are derived from continental tectospheric mantle and/or continental crust. As a corollary, enriched components with negative ε_{Nd} values are difficult to obtain directly from metamorphosed ocean crust. Finally, the combination of components in the above-mentioned eclogitic diamonds must be assembled and stored in stable upper mantle at depths of 150–200 km (ref. 14) on a 1,000-Myr timescale. Such eclogitic diamonds therefore most plausibly reflect local entrapment, mixing and crystallization of asthenosphere-derived magmas (which may include crustal components recycled by subduction) in tectospheric mantle beneath the Kaapvaal craton during the Proterozoic. This ancient continental-mantle keel subsequently survived convective disruption leaving original peridotitic and later eclogitic diamonds available for sampling by kimberlite in the Cretaceous. □

Involvement of the oxygen minimum in benthic zonation on a deep seamount

LOW oxygen concentration in the seawater column reduces the abundance of midwater consumer populations[1,2], which can enhance the supply of undegraded organic matter reaching the benthos. Low oxygen concentration in the water at the bottom can exclude most tolerant species from benthic habitats[3–5]. The interception of the seafloor with pronounced oxygen-minimum zones can produce steep gradients in benthic assemblages. We now present evidence for this interaction on Volcano 7, an oceanic seamount penetrating the oxygen-minimum zone in the eastern tropical Pacific. Submersible observations revealed only a few benthic species at the summit (730–750 m), where oxygen levels were lowest. Just tens of metres below, megafaunal and macrofaunal abundances were extremely high. Sediment organic carbon, a benthic food indicator, was unusually high. We hypothesize that a dynamic low-oxygen interface physiologically restricts benthos on the upper summit, that the enriched sediment is a result of reduced consumption and degradation of sinking material in the oxygen-minimum zone, and that this high benthic food level supports the unusually high benthic abundance. Sharp benthic zonation associated with oxygen concentrations may also be preserved in the palaeoceanographic record[4,6].

Volcano 7, an inactive seamount[7] at 13° 23′ N, 102° 27′ W, of 20-km diameter, rises from a depth of 3,400 m to 730 m. Its benthic and pelagic ecology were studied with submersible and shipboard sampling (including conductivity temperature depth (CTD) hydrocasts, water samples, box cores, photography, plankton tows, current meters and sediment traps) on a cruise in November 1988. Benthic data from June 1984 are also discussed.

The eastern tropical Pacific is characterized by a shallow mixed layer and a pronounced oxygen minimum[8]. At the Volcano 7 site, the mixed layer was 22 m deep, and the base of the euphotic zone was at 85 m. Sharp peaks of fluorescence, particles, chlorophyll *a*, phytoplankton, protozoans and zooplankton occurred just below the mixed layer (Fig. 1). The core of the oxygen minimum zone (oxygen <0.5 ml per litre of seawater) occurred from median depths of 72–1302 m, and the lowest oxygen (≤0.1 ml per litre) from median depths of 288–1,077 m (Fig. 1*a*). Thus the base of the euphotic zone was within the oxygen-minimum zone, and particles sinking out of the euphotic zone immediately entered a broad region of low oxygen and reduced plankton abundance.

There is evidence that undegraded surface-derived material reached the seamount summit. Bottom-moored particle interceptor traps[9,10] collected intact microplanktonic organisms common in surface waters. Excess Pb-210 activity profiles[11] indicated high sedimentation rates on the summit of 0.3–0.7 mm yr^{-1}. Sediment organic carbon (up to 3.9%), organic nitrogen (up to 0.55%), chlorophyll *a* (up to 25 μg g^{-1}) and sediment bacterial abundances were remarkably high on the summit, especially at depths <770 m (Fig. 2). Here, C/N ratios were near 7.0 (Fig. 2*c*), indicating the presence of fresh organic matter[12]. Green flocculent material was present on the bottom in both November 1988 and June 1984. The supply of undegraded organic material to the benthos may be more continuous in this region of reduced seasonality[13] than in higher latitudes, where benthic fluxes are strongly seasonal[14,15].

Strong megafaunal zonation was observed on the summit of the seamount (Figs 3 and 4). The uppermost summit (<750 m) was visibly depauperate (Fig. 3*a* and *b*). Gradual increases in megafauna occurred in a transition zone from 750–770 m.

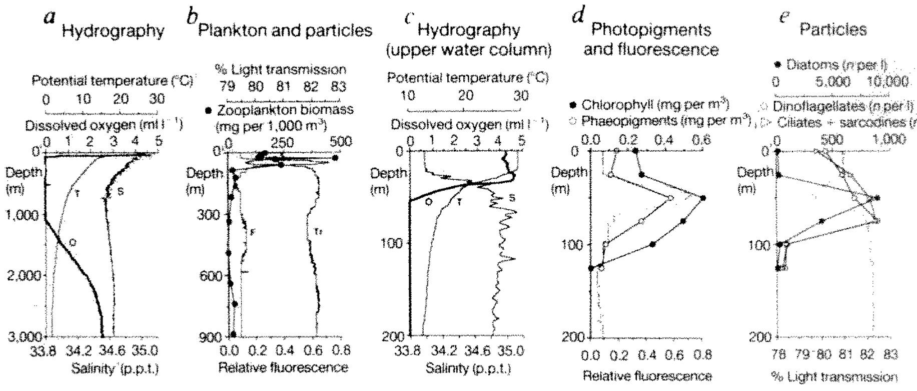

FIG. 1 Vertical profiles through the water column of physical, biological and chemical parameters. The sharp shallow thermocline is also an abrupt transition from oxygenated mixed-layer water to the very low-oxygen water in the oxygen-minimum zone. Concentrations of organisms (day and night), photopigments and particles peak sharply within the thermocline, then drop abruptly to low levels in the oxygen-minimum zone. Temperature, salinity and dissolved oxygen in the water column were measured with a SBE 19 Seacat CTD Profiler. Dissolved oxygen concentrations were calibrated by the Winkler titration method[26] on individual water samples from hydrocasts, and the oxygen values from the CTD electrode were transformed on the basis of a linear equation relating the two sets of measurements. Thirty-one CTD casts were made at locations on the seamount and along north–south and east–west transects extending up to 40 km from the summit. Data from the downcast of a representative CTD profile above the seamount are shown in *a* (whole water column) and *c* (upper 200 m detail). Zooplankton were obtained in 15 vertically stratified tows (nine samples per tow) at various locations on and near the seamount by a 1 m^2 MOCNESS (ref. 27) multiple opening and closing plankton net system using 335-μm mesh nets. Wet-weight zooplankton biomasses from a night-time tow series above the seamount are plotted in *b*. Relative fluorescence was measured by a Sea Tech *in situ* fluorometer and % light transmission by a Sea Tech 25-cm beam transmissometer, both attached to the MOCNESS. Representative profiles are shown in *b* and *e*. Fluorescence and light transmission data shown in *b* were smoothed with a five-point running mean. Fluorescence data in *d* were smoothed with a three-point running mean. Chlorophyll *a* and phaeophytin values (*d*), from water overlying the seamount, are means of two or three water samples per depth with two 500-ml aliquots per sample. Measurements were made fluorometrically[28] on water collected with Niskin bottles and filtered onto GFF filters. Abundances of diatoms, dinoflagellates and ciliate plus sarcodine protozoa (*e*) are means of three counts from water overlying the seamount (*n* per litre). Aliquots of 100 ml were drawn from Niskin bottles, preserved with Lugol's iodine, settled in settling chambers, and the entire sample was counted under an inverted microscope (magnification, ×170).

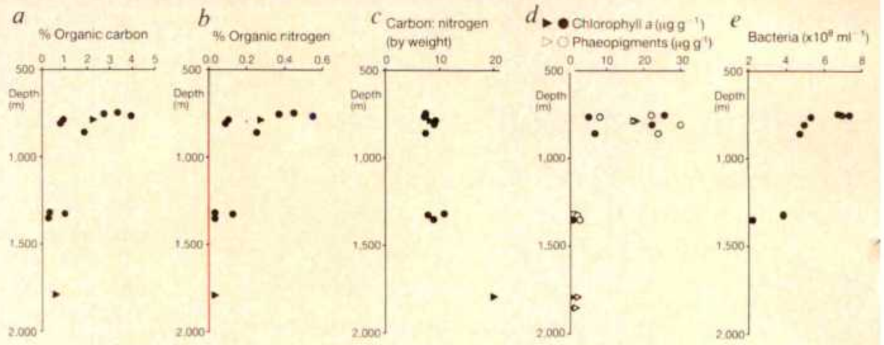

FIG. 2 Sediment organic matter properties. 1984 data, ▲; 1988 data, ●. Analyses of organic carbon (*a*), nitrogen (*b*), C/N (*c*), and chlorophyll *a* (▲, ●) and phaeopigments (△, ○) (*d*) were made on sediments collected by the submersible in tube cores and frozen at −70 °C. Organic C and N were analysed on the 0–2 cm vertical fraction. Sediments were homogenized, dried and ground, inorganic carbon was leached with 10% phosphoric acid for 24 h, then sediments were rinsed with organic-free distilled water, centrifuged, and the supernatant was decanted. The leaching process was repeated three times and remaining sediments were freeze-dried, weighed, ground and analysed on a Carlo Erba elemental analyser. Sediment chlorophyll *a* and phaeopigments were determined for 3 g sediment from the upper 1 cm using the spectrophotometric method[28] modified for sediments. Immediately on retrieval of tube cores, sediment bacteria (*e*) (1 ml from the top 1 cm) were sampled and preserved in 9 ml of 2.5% glutaraldehyde. Counts were made in the laboratory within two months of collection, using acridine-orange staining and epifluorescence microscopy[29]. There were significant differences (by analysis of variance) between upper (<770 m) and lower (770–900 m) summit locations for organic C ($P=0.015$) and N ($P=0.012$). Differences between summit (combined) and flank values were observed for organic C ($P=0.027$), organic N ($P=0.023$), chlorophyll *a* ($P=0.009$), phaeopigments ($P=0.001$) and bacteria ($P=0.004$).

Extraordinarily high densities (up to 19 individuals per m^2 in patches) occurred from 780–1,000 m, with maxima from 800–810 m (Figs 3*c*, *d* and 4*a*–*f*). Below 1,000 m, average megafaunal abundances (excluding xenophyophores) never exceeded 0.5 per m^2. This zonation did not correspond to the distribution of hard and soft substrates, and no hydrothermal activity was observed.

Abundance patterns of infauna, obtained in Ekman-style box cores, differed with size. Macrofauna (>300 μm) were rare above 750 m, with only low-oxygen-tolerant forms[16,17] present. Macrofauna increased greatly from the uppermost zone to 800–1,000 m (8,444 per m^2), then declined downslope (Fig. 4*g*). Meiofauna (smaller infauna), which are more tolerant than macrofauna to hypoxia[18], were most abundant at depths <750 m (202, 100 per m^2, $n=2$) (Fig. 4*h*). The nematode to harpacticoid copepod ratio, an indicator of oxygen stress[19], was 546:1 on the uppermost summit and declined to 1.3:1 on the flank (Fig. 4*i*).

Oxygen in near-bottom water samples obtained by submersible was 0.08–0.09 ml per litre ($n=2$,733–746 m) in the uppermost summit region of low megafaunal and macrofaunal abundance and 0.11–0.16 ml per litre ($n=3$,806–815 m) in the region of highest abundance. In five of six seamount CTD casts, oxygen was lower at 730 m than at 800 m, but there was considerable overlap in the concentration range measured at these two depths. Diurnal and semidiurnal temperature fluctuations (0.5 °C) occurred at the summit, indicating that internal tides were displacing water masses. This suggests that benthic organisms on the summit were exposed to periodically varying oxygen rather than to constant oxygen concentrations. Physiological exclusion of benthos at dynamic oxygen interfaces may therefore be a function of amplitude and temporal variation as well as absolute oxygen concentrations.

Very low plankton abundances are associated with oxygen minimum zones in the water column in parts of the Arabian Sea and the eastern Pacific, but only where oxygen is less than about 0.15 ml per litre throughout a broad depth interval[1,2], similar to the Volcano 7 region. At locations with more oxygen, plankton biomass may not be reduced, although distributions may be altered[1,20–22]. For midwater crustaceans, an oxygen concentration of 0.13 ml per litre is a critical lower oxygen limit for

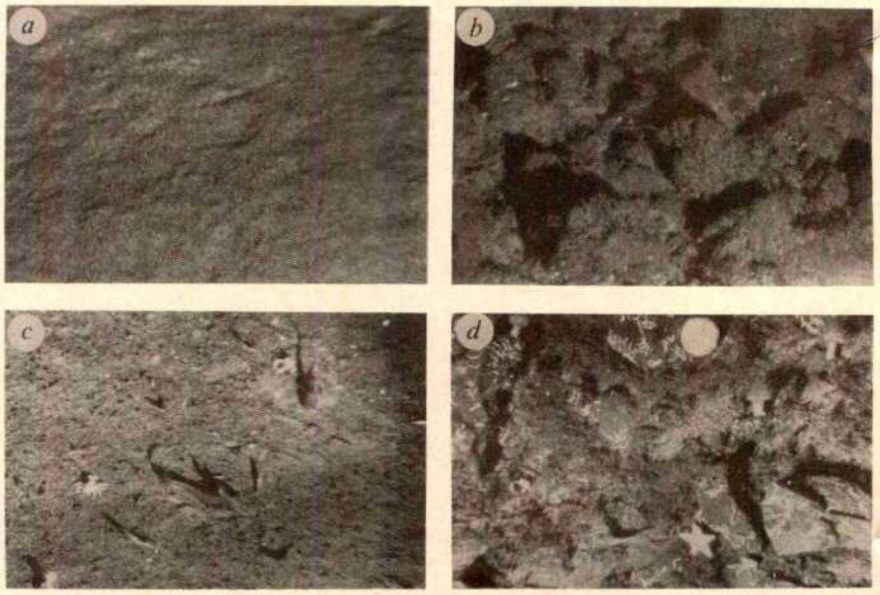

FIG. 3 Representative photographs of the upper summit (*a*, *b*; 744 and 734 m respectively) and lower summit (*c*, *d*; 770 and 780 m respectively). *a* and *c* show foraminiferal sand substrate, whereas *b* and *d* show rocky and mixed substrate. The only megafauna on the upper summit (*a*, *b*) were occasional rattail fish (*Nezumia liolepis*, shown in *c* and *d* but not in upper summit photographs) and solitary sessile coelenterates under rocks (White dots in *b*). Rock surfaces appear fuzzy (*b*, *d*) because of dense mats of an unidentified tube-building protozoan. Dark green detrital material was visible on rocks and sediments. Upper summit (*a*) meiofauna included large numbers of nematodes. The most abundant macrofauna were an aplacophoran (family Lepidomeniidae), a paraonid polychaete (*Cirrophorus lyra*), a dorvilleid polychaete (*Protodorvillea* sp.) and a few pogonophorans. A variety of abundant megafauna occurred on both rocks and sediments on the lower summit (*b*, *d*). Rattail fish (*N. liolepis*), galatheid crabs (*Munidopsis c.f. hystrix*), shrimp, starfish, sponges, anemones, ophiuroids and serpulid worm tubes (*Hyalopomatus marenzelleri*) are some of the organisms in *c* and *d*. Here, dark green or green-grey flocculent material occurred in depressions. Infaunal densities were high for sand substrates (>8,000 per m^2), and dominant infauna included cirratulid, sabellid and dorvilleid polychaetes and burrowing anemones. These photographs were taken with a hand-held 35-mm camera from inside the *Alvin* submersible and show an area of 2–3 m^2. For scale, the galatheid crabs are about 5 cm from claw tip to tail.

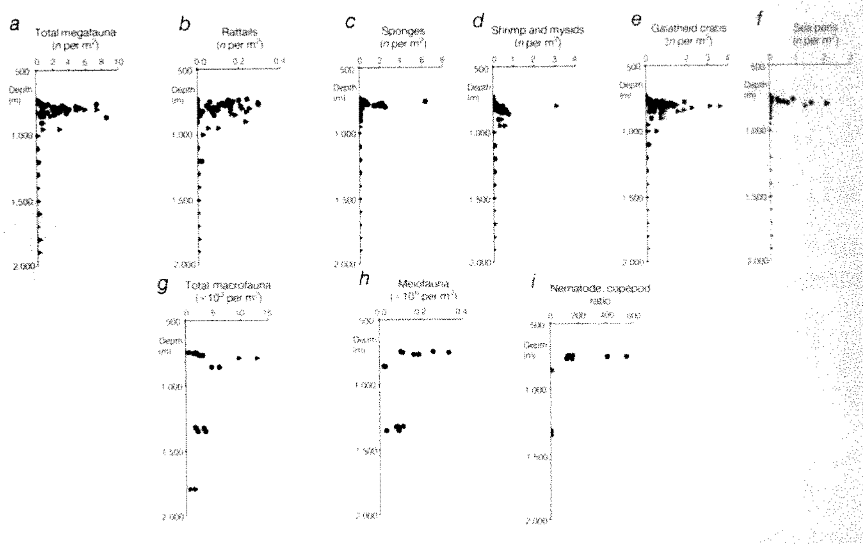

FIG. 4 Benthic faunal densities on the summit and flank as a function of water depth. 1984 data, ▲; 1988 data, ●. Megafaunal abundances were quantified from 1988 *Alvin* photographs (external hull-mounted camera) using a perspective grid to calculate surface area, and from 1984 *Angus* camera sled photographs, in which area was calculated as 1.25 sled altitude ×1.8 sled altitude. Mean faunal densities are shown for 10-m depth intervals 730–850 m, for 50-m intervals 850–1,000 m, and for 100-m intervals 1,000–2,000 m. Data from photographs taken on different parts of the seamount (at comparable depths) are plotted separately. Maximum densities of major taxa (1984 photographs) were 4.3 per m^2 for sponges, 9.7 per m^2 for galatheid crabs, 7.3 per m^2 for combined shrimp and mysids, 1.8 per m^2 for rattail fishes and 4.9 per m^2 for sea pens. For analysis of variance statistics, the upper summit includes data from 730–770 m and the lower summit, from 770–1,000 m. *a*, Total megafauna, excluding xenophyophores and the solitary coelenterates attached to rock bases on the upper summit. These groups were excluded because they were not reliably visible in *Angus* photographs. There were significant differences between the upper and lower summit ($P=0.036$) and the summit and flank ($P<0.001$). *b*, Rattail fishes (*N. liolepis*). Fish were ~15–20 cm long. There were significant differences between the upper and lower summit ($P=0.033$) and between the summit and flank ($P<0.001$). *c*, Total sponges. At least three unidentified species were present. There were significant differences between the summit and flank ($P=0.020$). *d*, Combined shrimp (*Heterocarpus nesisi* and *Benthescymus altus*) and mysids (*Boreomysis* sp.). Nearly significant differences were observed between summit and flank sites ($P=0.066$). *e*, Galatheid crabs (*M. c.f. hystrix*). Crabs are ~5-cm long. There were significant differences between upper and lower summit sites ($P=0.003$) and between summit and flank sites ($P<0.001$). *f*, Unidentified sea pens. These were present only on soft substrates and were ~15-cm long. *g*, Total macrofauna retained on a 300-μm screen. Samples were taken in Ekman-style box cores (196 cm^2 surface area) to a depth of 15 cm. Samples were preserved on board ship in 10% buffered formalin and later transferred to alcohol and sorted in the laboratory. Each data point represents macrofauna from one box core converted to *n* per m^2. There were significant differences between upper and lower summit sites ($P=0.003$) and between summit and flank sites ($P=0.051$). *h*, Total meiofauna (excluding foraminifera) retained on a 63-μm screen. Samples were taken from one subcore (49 cm^2 surface area) within each box core, processed as described above. Only the upper 5 cm of sediment were sorted for meiofauna. There were significant differences between the upper and lower summit ($P=0.044$). *i*, Nematode to harpacticoid copepod abundance ratios in the meiofauna cores. There were significant differences between summit and flank sites ($P=0.019$).

aerobic metabolism, although some vertical migrators can transit narrow low oxygen zones, or live anaerobically or at very low metabolic levels (in diapause, for example) for periods of time[23]. A pronounced oxygen-minimum zone that is vertically broad is therefore an effective barrier for most plankton. In this situation, the use of particulate material in midwater would be reduced, presumably enhancing benthic particulate fluxes.

Other interactions between the seamount and flow field could also mediate effects of the oxygen minimum. The high regional productivity of the eastern tropical Pacific[13] could be supplemented near Volcano 7 by topographically induced upwelling[24], which could contribute to the particle flux to the benthos. But, no definitive evidence of upwelling into the euphotic zone (which already extended below the mixed layer) was observed. Current acceleration over topographic features is an alternative process that may enhance local abundances of suspension-feeding megafauna on seamounts[25]. Although high abundances of some species occurred on ridges, the general megafaunal abundance peak on the summit of Volcano 7 did not correspond to exposed topography and included many non-suspension-feeding taxa.

We hypothesize that the striking benthic zonation on Volcano 7 is due to effects of the oxygen-minimum operating both in the water column (by enhancement of undegraded particulate food supply) and on the benthos (by exclusion of hypoxia-sensitive taxa). Oxygen minima also intersect the sea floor on continental slopes, as in the Arabian Sea[5], and the distinctive benthic faunal gradients produced by these interactions could be preserved in the palaeoceanographic record[4,6]. ☐

Evolution of the MHC class I genes of a New World primate from ancestral homologues of human non-classical genes

David I. Watkins*, Zheng W. Chen*, Austin L. Hughes†, Mark G. Evans*, Thomas F. Tedder‡ & Norman L. Letvin*

THE products of the classical human major histocompatibility complex (MHC) class I genes (*HLA-A, -B, -C*) are highly polymorphic molecules that bind peptides and present them to T lymphocytes[1–4]. The non-polymorphic, non-classical MHC class I gene products (*HLA-E, -F, -G*) are not restricting elements for the majority of T lymphocytes[5–7]. The evolutionary relationship of the non-classical and classical MHC class I genes is unclear. Here we present the cloning and sequencing of the MHC class I genes of a New World primate, the cotton-top tamarin (*Saguinus oedipus*). The expressed MHC class I genes of this species are more closely related to the human non-classical *HLA-G* (ref. 7) gene than they are to genes of the human classical *HLA-A, -B,* and *-C* loci. These observations imply that classical and non-classical genes do not necessarily constitute mutually exclusive groups over evolutionary time.

In contrast to other species[8], the MHC class I diversity of the cotton-top tamarin is limited[9]. Only 11 different MHC class I molecules were found in 79 unrelated tamarins (data not shown). To investigate the reasons for this limited MHC class I diversity, we have cloned full-length MHC class I complementary DNA from tamarins using conventional techniques[10] and the polymerase chain reaction[11] (PCR). Fortunately, all 11 tamarin MHC class I genes were expressed by the lymphocytes of three animals (numbers 100-75, 779-76 and 46-85). MHC class I cDNAs were isolated from these three animals and transfection of these cloned cDNAs into COS cells demonstrated that we had cloned all of the previously defined expressed tamarin genes (Fig. 1).

To ensure that we had isolated all of the expressed tamarin MHC class I genes, another set of primers was used to amplify exons 2 and 3 from RNA and DNA from animal 100-75. Only the three previously isolated cDNAs were amplified from RNA from this animal. In screening genomic clones, the three previously characterized cDNAs and three additional genes (*N1, N2, N3*) were defined (data not shown). *N2* was identical to cDNA 3 that had previously been cloned from animal 779-76. It is a gene with a premature termination codon in the cytoplasmic domain that was not expressed on the surface of lymphocytes from either animal 100-75 or 779-76. Both *N1* and *N3* contained deletions that would result in a premature termination codon or disrupt the folding of an MHC class I molecule (data not shown), indicating that they are pseudogenes. Thus, PCR amplification from genomic DNA did not reveal any additional intact tamarin MHC class I genes.

Analysis of the inter-locus variability in the human MHC class I genes shows that genes differ one from another by 50–100 bases in exons 2, 3 and 4. Intra-locus variability ranges from 1–50 bases in the same region[12]. Nucleotide sequences of the tamarin MHC class I genes were statistically less variable than those of human and mouse (Table 1). Accordingly, the predicted amino acid sequences of the tamarin MHC class I molecules were quite similar (Fig. 2). This similarity was especially striking in the transmembrane domain, in contrast to the highly variable MHC class I transmembrane domains of other species.

In phylogenetic trees[13] of exons 1-3, 4-7 and 1-7 (Fig. 3*a–c*), all but one of the tamarin cDNAs clustered with the human non-classical *HLA-G* MHC class I gene. The tamarin cDNA 3 was unique in that it was quite closely related to *HLA-F* (ref. 6). The presence of *HLA-G*- and *HLA-F*-specific substitutions in the predicted amino-acid sequences of the tamarin MHC

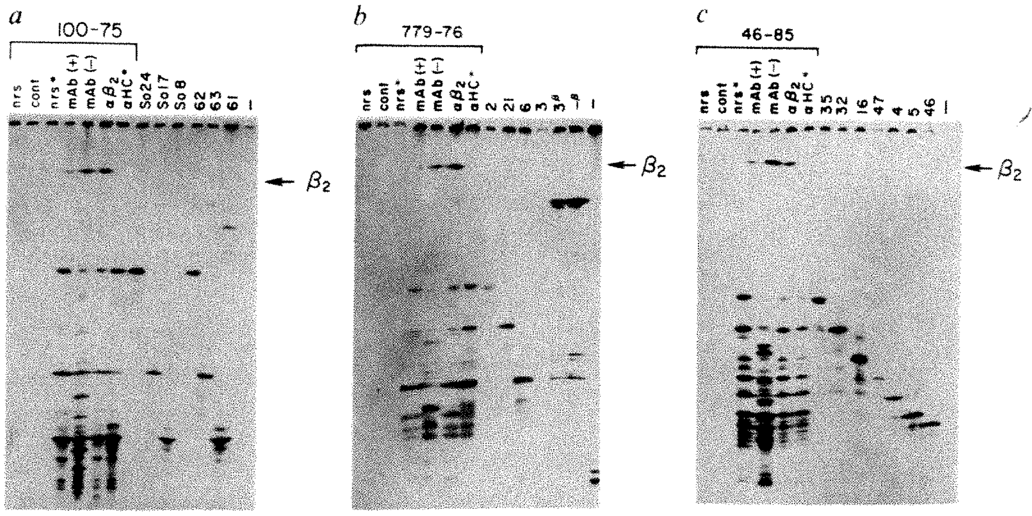

FIG. 1 Expression of seventeen cDNAs cloned from the lymphocytes of three cotton-top tamarins. *a*, PCR amplification of cDNA synthesized from RNA was used to clone full-length tamarin MHC class I cDNAs. Three MHC class I heavy chains and β_2-microglobulin (β_2) were precipitated[28] from the lysate of a biosynthetically labelled, EBV-transformed B-cell line from animal 100-75 using the monoclonal antibody BB7.7 (mAB). Precipitates were either left untreated (−) or sialic acid residues were removed with neuraminidase (+). A rabbit antiserum reactive with human β_2-microglobulin ($\alpha\beta_2$) and one reactive with denatured human heavy chains (αHC) also precipitated the same three tamarin MHC class I molecules. Normal rabbit serum (nrs) and a monoclonal antibody (cont) reactive with an irrelevant determinant were used as controls. Lysates were denatured (*) in some instances. Three cDNAs cloned from a cDNA library made from an EBV-transformed cell line from animal 100-75 (So24, So17 and So8)[10] and three cDNAs amplified by PCR[11,29] from cDNA synthesized from total cellular RNA isolated from the same cell line (62, 63 and 61) were transfected into COS cells. The sequences of the three PCR-amplified cDNAs (62, 63 and 61) differed by only 1 of 3,000 nucleotides from the sequences of those that were generated using standard cDNA cloning techniques (So24, So17 and So8). As a control, COS cells were also transfected with the mouse CD20 molecule (−). *b*, COS cells were transfected with four different cDNAs (2, 21, 6 and 3) isolated by PCR amplification of RNA from lectin-stimulated peripheral blood lymphocytes (PBL) from animal 779-76. MHC class I molecules from COS cells transfected with cDNA 3 were also precipitated with an antiserum reactive with human β_2-microglobulin (β). *c*, COS cells were transfected with seven different cDNAs (35, 32, 16, 47, 4, 5, and 46) isolated by PCR amplification of RNA from lectin-stimulated PBL from animal 46-85.

FIG. 2 Predicted amino-acid sequences of the tamarin MHC class I cDNAs compared with the amino-acid sequences of *HLA-A*, *-B*, *-C*, *-E*, *-F* and *-G*. The sequence of the tamarin consensus is given and identity with this is indicated (–). The *HLA-A*, *-B*, *-C* consensus sequence is from 39 human sequences[1]. △ under the *HLA-G* sequence marks positions at which *HLA-G*-specific amino-acid substitutions are found in the tamarin but not the consensus *HLA-A*, *-B* and *-C* sequence. ▲ under the *HLA-G* sequence marks positions at which *HLA-G*-specific amino-acid substitutions are found in the tamarin, but not in any of 39 individual *HLA-A*, *-B -C* sequences[1]. △ under the *HLA-F* sequence marks positions at which *HLA-F*-specific amino-acid substitutions are found in So-3 but not in the *HLA-A*, *-B*, *-C* consensus sequence. ▲ under the *HLA-F* sequence marks positions at which *HLA-F*-specific amino-acid substitutions are found in So-3 but not in any of 39 individual *HLA-A*, *-B*, *-C* sequences[1].

METHODS. PCR from RNA was carried out as described previously[29]. The two sets of primers used in these studies have also been used to clone 21 cDNA *HLA-A*, *-B* and *-C* homologues from the lymphocytes of chimpanzee, pygmy chimpanzee, gorilla, orang-utan and gibbon and can therefore amplify *HLA-A*, *-B* or *-C* homologues (data not shown). Primer pairs used for amplification of full-length cDNAs from RNA were: 5′-GCAAGCTTATGACGGTCATGGCTCCCCGAACC-3′ and 5′-GCGAATTCAGTCCCACACAAGGCAGCTG-3′. Primer pairs used for amplification of exons 2 and 3 from RNA and genomic DNA were 5′-GCGAATTCGCTCCCACTCCATGAGGTATTTC-3′ and 5′-GCAAGCTTGCGCTGCAGCGTCTCCTTCCC-3′. Both strands of each PCR-generated isolate were sequenced[30] using oligonucleotide primers specific for MHC class I molecules and compressions resolved using dITP. These overlapping sequences were assembled (digitizer and software from IBI, New Haven, Connecticut) and aligned using programs from the University of Wisconsin Genetics Computer Group. To avoid PCR-generated errors[31] several copies of each isolated clone were sequenced as follows: So-24 (4), So-17 (2), So-8 (2), So-21 (3), So-6 (3), So-3/*N2* (4), So-32 (4), So-16 (3), So-47 (4), So-4 (7), So-5 (4), So-46 (3), *N1* (5) and *N3* (5). There are 8–11 MHC class I genes in the tamarin as indicated by Southern blot and hybridization of *Eco*RI- or *Hin*dIII-cut genomic DNA with MHC class I probes (data not shown).

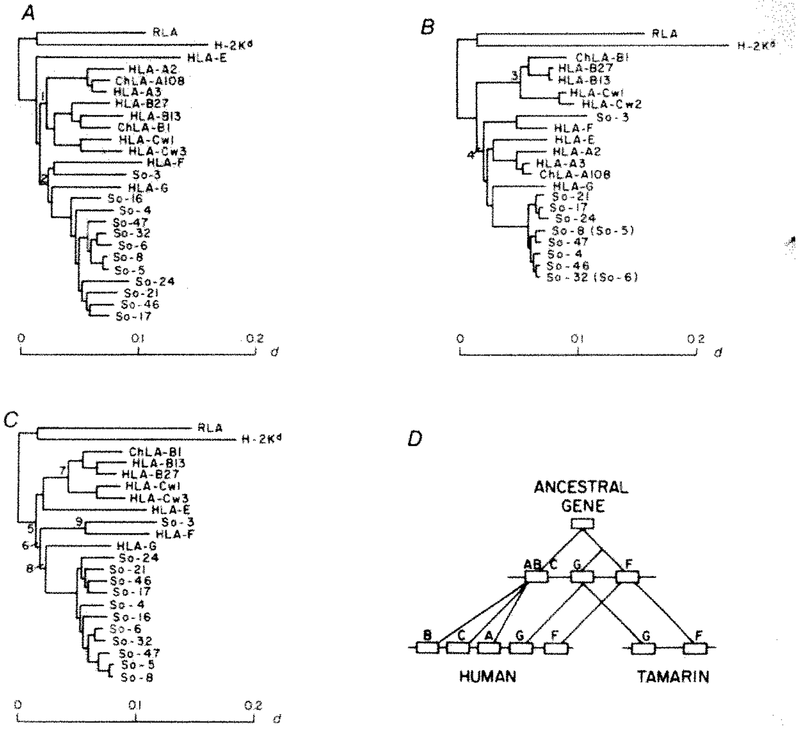

FIG. 3 The tamarin MHC class I genes are related to the *HLA-G* and *-F* non-classical genes. Trees were constructed for different regions of the MHC class I gene to clarify the relationship between the human and tamarin genes. This was necessary because the *HLA-A* locus, as it now exists, is the product of a recombination between an ancestral *HLA-A* locus and an *HLA-E*-like locus. As a result of this event (which antedated the human-chimpanzee divergence), the sequence of *HLA-A* (and of *ChLA-A*) 3' to the third intron is *HLA-E*-like and not closely related to other human classical MHC class I genes[32]. Phylogenetic trees based on nucleotide substitutions per site (*d*) among cotton-top tamarin and other primate MHC class I genes: *A*, tree for 591 aligned nucleotides from exons 1-3; *B*, tree for 414 aligned nucleotides from exons 4-7; *C*, tree for 1,005 aligned nucleotides from exons 1-7. In all cases rabbit (*RLA*) and mouse (*H-2K^d*) MHC class I genes are used as outgroups to establish the root of the tree. Significance of selected internal branch lengths was tested by the method of Li[33]. In *A*, the internal branch d_{12} (between the human classical gene cluster and the human non-classical/tamarin cluster) is significant at the 5% level (t = 2.05). In *B*, the internal branch length d_{34} (between the cluster containing tamarin genes, human non-classical genes and this region of the *A* alleles and the cluster containing *B* and *C* alleles) is significant at the 0.1% level (t = 4.10). In *C*, the internal branch d_{67} (between the cluster containing the tamarin genes, *G* and *F* and the cluster of human and chimpanzee classical genes) is significant at the 0.1% level (t = 4.61); the internal branch d_{89} (between the *F*/*So*-3 cluster and the cluster containing *G*, and the other tamarin sequences) is significant at the 0.1% level (t = 6.20); the internal branch d_{58} (between the *G*-human classical branch point and the *G*-tamarin branch point) is significant at the 5% level (t = 2.09); and the internal branch length d_{59} (between the *F*-human classical branch point and the *F*-So-3 branch point) is significant at the 0.1% level (t = 6.33). The fact that d_{58} and d_{59} are significant is evidence that *G*, *F* and the ancestor of human classical class I genes existed before the separation of Old and New World primates. *D*, Schematic representation of a hypothetical evolutionary history of tamarin and human MHC class I genes. This figure is not intended to represent relative chromosome positions of the various genes.

class I molecules supports the results of this phylogenetic analysis (Fig. 2). Gene trees based on the partial nucleotide sequences available for *N1* and *N3* were also constructed. These two genes were also related to the *HLA-G* locus (data not shown). Thus, all tamarin MHC class I genes have evolved from ancestral homologues of human non-classical MHC class I genes.

We could find no evidence for the presence of tamarin MHC class I gene products related to human HLA-A, -B or -C molecules. Antibodies against human MHC class I molecules precipitated only the three HLA-G-related products from a B-cell line from animal 100-75. Synthesis of a cDNA library from this cell line using conventional techniques[10] and PCR amplification using two different primer pairs also demonstrated that only these three MHC class I genes were expressed. As tamarins can mount CD8$^+$ cytotoxic T-cell responses[14], it is likely that their HLA-G-related MHC class I molecules are functional. These observations suggest that HLA-G-related MHC class I genes constitute the classical MHC class I genes of the tamarin. This implies that classical and non-classical MHC class I genes need not constitute mutually exclusive groups over evolutionary time.

TABLE 1 The variability of the expressed tamarin MHC class I genes is significantly lower than the variability of the human and mouse MHC class I genes

Species	Comparison no.	$d \pm$ s.e.m.	$d_s \pm$ s.e.m.	$d_N \pm$ s.e.m.
Cotton-top tamarin	55	4.7 ± 0.4	4.8 ± 0.8	4.7 ± 0.5
Human	66	8.7 ± 0.6*	13.9 ± 1.7*	7.1 ± 0.6*
Mouse	36	8.2 ± 0.5*	7.1 ± 1.0	8.6 ± 0.6*

Comparisons of mean numbers of nucleotide substitutions per site (d), per synonymous site (d_s) and per non-synonymous site (d_N); expressed as percentages in alpha-1, alpha-2 and alpha-3 domains (822 nucleotides) of cotton-top tamarin, human and mouse MHC class I molecules. d is estimated by the Jukes-Cantor method[24], d_s and d_N are estimated by the Nei and Gojobori method[25], standard errors are estimated by the Nei and Jin method[26]. See ref. 27 for human and mouse sequence references.

* Means for mouse and human that differ significantly (0.1% level) from the corresponding means for tamarin.

A phylogenetic analysis of human and tamarin MHC class I sequence data (Fig. 3) suggests that the last common ancestor of humans and tamarins had at least the following MHC class I genes: *G*, *F* and the ancestors of *A*, *B* and *C*. Both the tamarin MHC class I *G*-related and *F*-related genes appear to have diverged from the ancestral *G* and *F* genes after they had split from the ancestor of the *HLA-A*, *-B* and *-C* genes. This hypothesis is supported by the significant branch length (d_{58}, Fig. 3*c*) between *G* and the branch point of the ancestor of *HLA-A*, *-B* and *-C* (5) and *G* and the branch point of the tamarin *G*-related genes (8). The *F* gene also diverged from *G* after *G* had split from the ancestor of *A*, *B* and *C* as indicated by a similar significant internal branch length (d_{59}, Fig. 3*c*). Therefore, as both *G* and *F* diverged from *ABC* before the derivation of the tamarin genes and as *G* and *F* are both present in tamarins and humans, the MHC chromosome of the last common ancestor of humans and tamarins probably had genes for *G*, *F* and *ABC* (Fig. 3*d*).

Hybridization studies[15] and sequence analyses[16] had suggested that non-classical MHC class I genes may not be conserved in different orders of mammals. The isolation of a chimpanzee *HLA-F* cDNA[12], however, demonstrates that non-classical loci can be shared by closely related mammalian species. The finding in the tamarin of a gene related to *HLA-F* that is not expressed shows that non-classical MHC class I loci can be preserved for much longer than was previously thought.

The remarkable lack of variation and polymorphism at the MHC class I loci of the tamarin may explain, in part, the extreme susceptibility of these New World primates to a variety of viral pathogens. Tamarins succumb to a fatal lymphoproliferative syndrome when infected with Epstein-Barr virus (EBV), *Herpesvirus saimiri* and *H. ateles*[17,18]. They also die following infection with Rous sarcoma virus, measles and parainfluenza viruses[17].

As individual MHA class I glycoproteins can probably bind and present only a restricted number of viral peptides to T cells, reduced variability in the species' MHC class I glycoproteins may render tamarin MHC class I molecules unable to bind a diversity of viral peptides. This may leave the tamarin susceptible to fatal infections by pathogens to which it is not exposed in its natural environment.

Finally, it is interesting to speculate as to the evolutionary pressures that might have selected for deletion of the *HLA-A*, *-B*, and *-C* in the tamarin and utilization of *HLA-G*-related MHC class I genes. Most tamarins are born as stable bone marrow-chimaeric fraternal twins[19]. MHC class I similarity between genetically disparate, coexisting cell populations would facilitate this chimaerism. Indeed, it has recently been demonstrated that cells at the interface of the human maternal and fetal circulations in the extravillous trophoblast do not express detectable classical HLA class I molecules[20,21]. Rather, these fetal cells express products of the non-polymorphic, non-classical *HLA-G* genes[22,23]. Utilization of relatively non-polymorphic MHC class I genes may be a mechanism by which MHC class I functions can be served with a minimum stimulation of alloreactivity. □

Inhibition by brefeldin A of presentation of exogenous protein antigens to MHC class II-restricted T cells

PEPTIDES bound to class I or class II major histocompatibility complex (MHC)-encoded molecules are ligands for the antigen-specific T-cell receptor of T-cells carrying the CD8 and CD4 antigens, respectively[1]. MHC class I-restricted T cells generally recognize peptides derived from processing of endogenously synthesized cellular antigens, whereas class II-restricted T cells usually recognize peptides derived from exogenous antigens entering antigen presenting cells. Accordingly, two separate pathways of antigen processing and presentation have been proposed[2,3]. The fungal metabolite brefeldin A (BFA)[4], an inhibitor of protein transport from the endoplasmic reticulum[5–7], inhibits presentation of endogenous antigens for MHC-restricted T-cell recognition[8]. The selectivity of BFA activity has been inferred to reflect presentation of a given antigen processed through the cytosolic or the endocytic route[9,10]. Here we show that BFA also greatly inhibits the presentation of exogenous protein antigens by MHC class II molecules to T cells, indicating a broader effect of this drug on antigen presentation and an additional similarity between the two processing pathways. As cycloheximide, a protein synthesis inhibitor, also inhibits presentation of protein antigens to class II-restricted T cells, the data indicate that peptides generated by processing of exogenous proteins bind to newly synthesized class II molecules for presentation to T cells.

To test the effect of BFA on the presentation of exogenous protein antigens to MHC class II-restricted T cells, LK-35.2 cells (a B-cell hybridoma expressing I-$A^{k,d}$ and I-$E^{k,d}$ molecules) were treated with BFA during a 4-h pulse with hen egg-white lysozyme (HEL) or chicken ovalbumin (Ova). After washing these antigen presenting cells (APC), antigen presentation to the HEL-specific T-cell hybridoma 1H11.3 or Ova-specific hybridoma DO11.10 was assessed by measuring T-cell growth factor (interleukins 2 and 4) production. Incubation of APC with 3 μM BFA abrogates their capacity to present exogenous protein antigens (Fig. 1*a*, *b*). If, under the same conditions, APC are pulsed with the HEL peptide 105–120 (recognized by hybridoma 1H11.3 with I-E^{d} molecules[11]) or with the Ova peptide 323–339 (recognized by hybridoma DO11.10 with I-A^{d} molecules[12]), BFA has no effect. Titration of interleukins produced by peptide-activated T-cell hybridomas also did not show any effect of BFA on antigen presentation (data not shown). These results demonstrate that BFA inhibits the presentation of exogenous soluble proteins recognized by T cells with MHC class II molecules, but has no effect on the ability of APC to present synthetic peptides.

The effect of BFA on antigen presentation can be partially overcome by increasing the concentration of protein antigen during pulsing, using T-cell hybridomas responding to low antigen concentration (Fig. 1*c*–*h*). A similar effect is also exerted on LK-35.2 cells by cycloheximide, although this was not entirely predicted by previous work[13,14]. In fact, a remarkable concordance between BFA and cycloheximide in the inhibition of exogenous antigen presentation is observed. These results suggest that a less efficient, secondary pathway for class II-restricted antigen presentation, independent of *de novo* protein synthesis or of protein egress from the endoplasmic reticulum (ER), may be activated by pulsing the APC with high (at least 20-fold molar excess) protein antigen concentrations. Alternatively, the data may reflect incomplete inhibition of protein egress from the ER. Conversely, the lysosomotropic agent chloroquine inhibits antigen presentation at any concentration of protein antigen tested, indicating that BFA does not act as a lysosomotropic agent.

The inhibitory effect of BFA on the presentation of soluble proteins to class II-restricted T cells can be demonstrated in different types of APC, including B-hybridoma and B-lymphoma

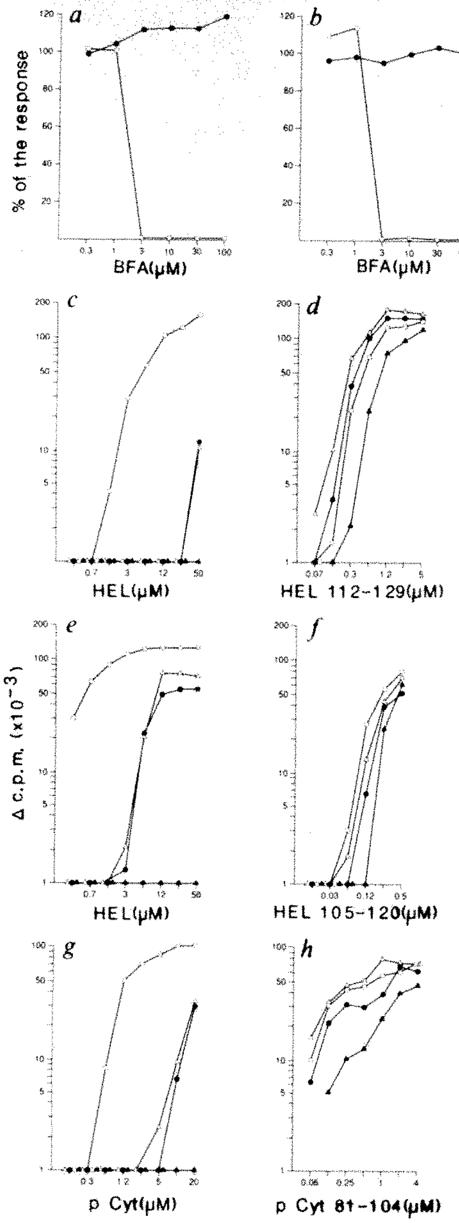

FIG. 1 Inhibition of antigen presentation by BFA. LK-35.2 APC (2.5×10^4 per well) were incubated with the indicated concentrations of BFA (Sandoz; M_r 280) and 15 min later antigen was added: *a*, 2 μM HEL (○) or 2 μM HEL peptide 105–120 (●); *b*, 250 μM Ova (○) or 1 μM Ova peptide 323–339 (●). After 4-h incubation at 37 °C, the APC were washed three times and 5×10^4 cells per well of hybridoma 1H11.3 (*a*) or DO11.10 (*b*) were added. After 24 h, antigen-specific T-cell growth factor production was determined by ^{3}H-labelled thymidine incorporation into CTLL cells (ref. 21). Data are presented as percentage of the c.p.m. (arithmetic mean of triplicate cultures) obtained in response to the protein antigen or to the peptide. Control responses in the absence and presence of protein and peptide were respectively: 660/75,578 and 515/81,181 (*a*); 528/54,904 and 568/93,175 (*b*). *c-h* LK-35.2 cells were incubated with 20 μM BFA (△), 350 μM cycloheximide (●) (Sigma), 200 μM chloroquine (▲) (Sigma), or left untreated (○). These compounds were added to APC 15 min, 2 h or 30 min, respectively, before addition of the indicated concentrations of protein antigens or synthetic peptides. After 4-h incubation with antigen, the APC were washed, fixed with 0.05% glutaraldehyde[21], washed again and the HEL-specific T-cell hybridomas 2C8.4, recognizing the HEL peptide 112–129 in association with I-A^k molecules[21] (*c*, *d*), 1H11.3 (*e*, *f*), or the pigeon cytochrome *c* (p Cyt)-specific T-cell hybridoma 2B4.11, recognizing the p Cyt peptide 81–104 in association with I-E^k molecules[22] (*g*, *h*), were added. The experiment was continued as in *a*, results are expressed as c.p.m. of ^{3}H-labelled thymidine incorporation into CTLL cells. Background proliferation of CTLL cells was 201 (*c*, *d*), 136 (*e*, *f*) and 150 (*g*, *h*) c.p.m.

METHODS. The synthesis, purification and analysis of HEL peptides and the establishment of T-cell hybridomas have been described previously[11,21]. Cultures containing 5×10^4 T-hybridoma cells and 2.5×10^4 LK-35.2 cells (American Type Culture Collection) were set up with or without antigen in 0.2 ml RPMI 1640 medium (Gibco) supplemented with 2 mM L-glutamine, 50 μM 2-mercaptoethanol, 50 μg ml^{-1} gentamicin and 10% FCS (Seromed). After 24 h of culture, 50 μl aliquots of supernatant were assayed for the presence of T-cell growth factors by ^{3}H-labelled thymidine incorporation in 10^4 CTLL cells[11].

cells (Fig. 2*a*), resident peritoneal adherent cells (Fig. 2*b*) and MHC class II-transfected L-cell fibroblasts (Fig. 2*c*). In the latter case, fibroblasts transfected only with I-E^d genes[15] or supertransfected with the invariant chain gene[16], were equally sensitive to BFA, suggesting that expression of the invariant chain does not influence the inhibition by BFA of protein antigen presentation to class II-restricted T-cells.

Addition of BFA to APC 1 h after HEL induces a much reduced effect on antigen presentation, and no effect 2 h after HEL, indicating that during this period a sufficient amount of protein had been processed to yield antigenic complexes stimulating an optimal T-cell response (Fig. 3*a*). Addition of BFA to APC any time after the HEL peptide 105–120, is ineffective (Fig. 3*b*). The inhibition of class II-restricted antigen presentation by BFA is rapidly and completely reversible, and washing the APC after 4-h incubation with BFA, just before the addition of HEL

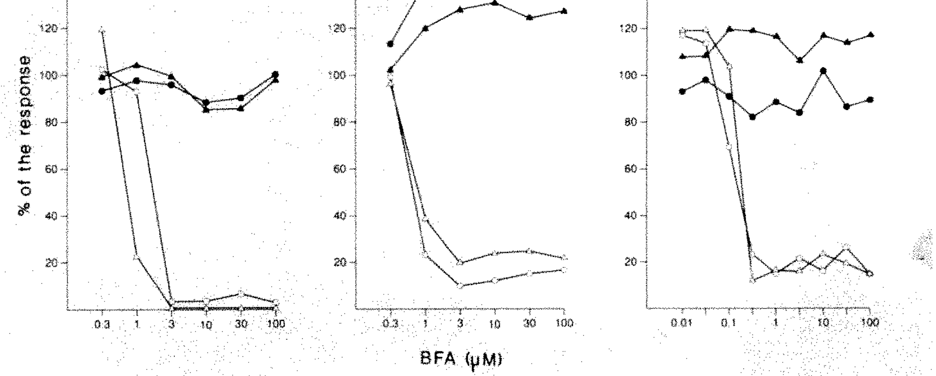

FIG. 2 Inhibition by BFA of the presentation of HEL by different APC. APC were incubated with the indicated concentrations of BFA and 15 min later 2 μM HEL (open symbols) or 2 μM HEL peptide 105–120 (closed symbols) were added. *a*, LK-35.2 (circles), A20 cells (triangles). *b*, Resident peritoneal cells enriched in macrophages by plastic adherence from BALB/c (circles) or DBA/2 mice (triangles). *c*, CA36.2.1 fibroblasts transfected with I-E^d genes[15] (circles) or CA36.2.1.li supertransfected with the invariant chain gene[16] (triangles). The experiment was then continued as in Fig. 1. Control responses of the I-E^d-restricted T-cell hybridoma 1H11.3 in the absence and presence of HEL and the HEL peptide 105–120 were respectively: 1019/134,776 and 861/142,914 (LK-35.2); 816/25,207 and 855/78,439 (A20); 711/45,344 and 435/31,413 (BALB/c); 863/61,174 and 671/46,062 (DBA/2); 285/36,898 and 346/95,105 (CA36.1.2); 360/21,515 and 256/76,398 (CA36.1.2.li).

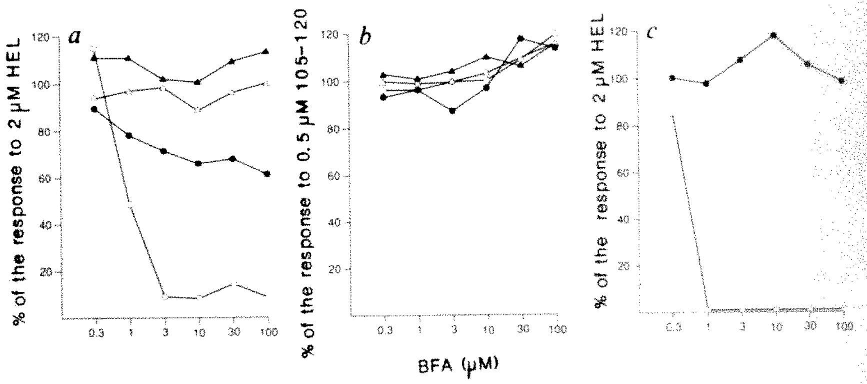

FIG. 3 The inhibition by BFA of HEL presentation is reversible and requires the presence of the drug during the antigen processing phase. *a,b*, LK-35.2 cells were incubated with 2 μM HEL (*a*), or 0.5 μM HEL peptide 105–120 (*b*) and the indicated concentrations of BFA were added 15 min before antigen (○), or 1 h (●), 2 h (△), 3 h (▲) after antigen. The experiment was then continued as in Fig. 1. Control responses of hybridoma 1H11.3 in the presence or absence of HEL and HEL peptide 105–120 were respectively: 745/164,340 and 816/165,197 c.p.m. *c*, LK-35.2 cells were incubated with the indicated concentrations of BFA and 15 min later 2 μM HEL was added. After 4 h, APC were washed, the I–E^d-restricted HEL-specific T-cell hybridoma 1E5.11 (ref. 11) was added, and the experiment continued as in Fig. 1 (○). Alternatively, LK-35.2 cells were incubated with BFA for 4 h, washed, pulsed with HEL for 4 h and the experiment continued as above (●). Control responses in the absence or presence of HEL were respectively 883 and 27,391 c.p.m.

and T-hybridoma cells, restores interleukin-2 (IL-2) production to control levels (Fig. 3*c*).

The effect of BFA on antigen presentation does not seem to be related to the amount of surface class II molecules expressed. No difference could be detected by surface immunofluorescence with anti-I-E^d antibody between untreated and BFA-treated cells (Fig. 4*c*), or in their antigen-presenting function, as peptide presentation to class II-restricted T cells is not affected by BFA treatment of APC.

But BFA affects the biosynthetic maturation of MHC class II molecules, as demonstrated by pulse-chase labelled LK-35.2 cells. Cells were immunoprecipitated with anti-I-A and anti-I-E monoclonal antibodies immediately after labelling and after a 3.5-h chase period. BFA retarded the biosynthetic maturation of both I-A (Fig. 4*a*) and I-E (data not shown) class II molecules, as lower relative molecular mass (M_r) α- and β-chain species were observed in BFA-treated (Fig. 4*a*; lanes 3, 4) but not in untreated cells (Fig. 4*a*; lanes 1, 2). These lower M_r species were sensitive to endoglycosidase H (endo H) treatment before and at the end of the 3.5-h chase period (Fig. 4*b*; lanes 6, 8), whereas class II molecules from untreated cells were sensitive to endo H treatment before the chase period, but acquired endo H resistance during 3.5-h post synthesis (Fig. 4*b*; lanes 2 and 4, respectively). The lower M_r I-A^k species present in BFA-treated cells before the chase period (Fig. 4*a*, lane 3 and *b*, lane 5) was converted to slightly larger species during the 3.5-h chase period (Fig. 4*a*, lane 4 and *b*, lane 7). Furthermore, an increased ability of the monoclonal antibody to immunoprecipitate I-A^k molecules after the chase period in BFA-treated cells is apparent (compare Fig. 4*a*, lanes 3, 4, and *b*, lanes 5, 7). This may represent continued processing of some of the carbohydrate chains of the I-A^k molecule during the BFA treatment. A similar situation has been described for the T-cell receptor α- and γ-chains, and was accounted for by the activity of *cis*-medial Golgi glycosidases and glycosyltransferases redistributed by BFA in the ER[6]. In contrast to the T-cell receptor α-chain, I-A^k molecules retain some sensitivity to endo H (Fig. 4*b*, lane 8). Thus, BFA treatment prevents complete maturation

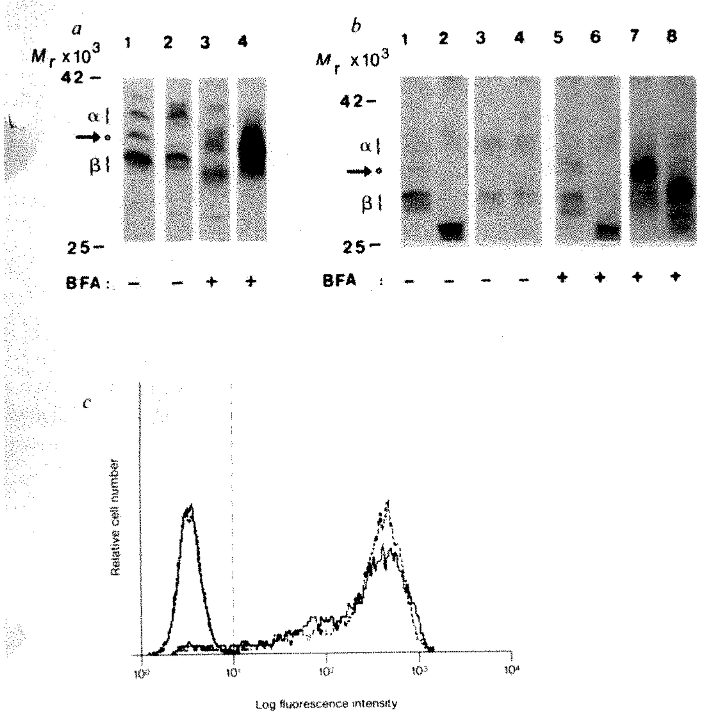

FIG. 4 Effect of BFA on the expression of class II MHC molecules. *a*, Anti-I–A^k immunoprecipitates from BFA-untreated (lanes 1, 2) or -treated (lanes 3, 4) cell lysates at 0 h (lanes 1, 3) or 3.5 h (lanes 2, 4) after start of chase period. *b*, Endo H sensitivity of class II molecules. Anti-I–A^k immunoprecipitates of lysates from 0 h (lanes 1, 2, 5, 6) and 3.5 h (lanes 3, 4, 7, 8) after the start of the chase period were digested with endo H. Lanes 1–4 and 5–8 represent immunoprecipitates from control and BFA-treated cell lysates, respectively. Mock- and endo H-digested immunoprecipitates are lanes 1, 3, 5, 7 and 2, 4, 6, 8, respectively. The upper and lower brackets to the left correspond to the position of the α- and β-chains of class II molecules, respectively, and the arrow to the position of the class II-associated invariant chain. The position of M_r standards are indicated. *c*, Cell surface expression of class II molecules. LK-35.2 cells were left untreated (solid line) or incubated with 100 μM BFA (broken line) for 4 h before staining with anti-I–E monoclonal antibody.

METHODS. *a,b*, LK-35.2 cells (2.5×10^6 ml^{-1}) were incubated with 10 μM BFA or left untreated and 15 min later metabolically labelled with 250 μCi ml^{-1} [^{35}S]methionine (Dupont, 1,100 Ci mmol^{-1}) in methionine-free medium containing 2.5% dialysed FCS for 30 min. Cells were then immediately harvested or chased for 3.5 h in complete medium, lysates were prepared from 5×10^6 cells per time point and immunoprecipitated as described[23] with the anti-I–A^k monoclonal antibody 10.2.16 or with an irrelevant antibody (not shown) and the resulting immune complexes washed as described[24]. Immunoprecipitates were analysed on 12% (*a*) or 10% (*b*) SDS-PAGE[25]. Immunoprecipitates were dissociated by heating for 5 min at 90 °C in 40 μl of 0.5% SDS. Half of the solubilized preparation was digested at 30 °C with 8 mU endo H (Genzyme) in 50 mM sodium phosphate buffer, pH 6.5, 0.05% SDS (lanes 2, 4) and the other half mock-digested (lanes 1,3). After 18 h, 10 μg RNA carrier transfer was added, the digest precipitated by adding four volumes of cold acetone, the precipitate centrifuged at 10,000*g* (10 min), and the resulting pellet analysed by SDS-PAGE. *c*, Cells were washed, incubated with biotinilated monoclonal antibody 14-4-4 (anti-I–E^d), washed, incubated with fluorescein isothiocyanate (FITC)-streptavidin and analysed using FACStar (Becton-Dickinson). The left peaks represent the fluorescence of cells not incubated with antibody.

of class II molecules in LK-35.2 cells, consistent with the BFA-induced inhibition of glycoprotein carbohydrate maturation due to failure of nascent proteins to leave the ER[5,6].

Our data demonstrate that the presentation of soluble exogenous proteins by class II molecules is, in contrast to earlier work[10], BFA-sensitive. The reason for this difference is not clear but could reflect the type of antigen, particulate or soluble, used. It has been suggested that BFA may not inhibit pigeon cytochrome *c* presentation by B-cell hybridomas to class II-restricted T-cells[8]. But the presentation of pigeon cytochrome *c* by LK-35.2 cells to the T-cell hybridoma 2B4.11 is clearly inhibited by BFA (Fig. 1*g*, *h*). It has also been suggested that BFA inhibits antigen presentation by macrophages but not by B-cell lymphomas[17]. In contrast, our data demonstrate a similar sensitivity to BFA for all the APC tested.

Different explanations could be envisaged for the BFA inhibition of exogenous antigen presentation to MHC class II-restricted T-cells: prevention of peptide generation, of peptide-class II association, or of egress of newly synthesized class II molecules from the ER. The first possibility is unlikely as BFA is probably not a lysosomotropic agent[5,8], and does not inhibit aspartyl, serine or metalloproteases (H. Wagner, unpublished data). But BFA might inhibit processing of exogenous antigens if processing requires the transport of newly synthesized proteolytic enzymes into the endosomes. The second possibility is not true for synthetic peptides, which can also directly bind to surface class II molecules. Although BFA may inhibit the association of intracellular peptides to class II molecules, peptides can still bind to MHC class I molecules in BFA-treated cells[18]. As BFA blocks protein egress from the ER, the third possibility would predict that encounter, likely in a *trans*- or post-Golgi location, of newly synthesized class II molecules with peptides derived by processing of exogenous proteins, could be prevented by BFA treatment of APC. Cycloheximide also inhibits antigen presentation, indicating that a continuous flow of newly synthesized MHC class II molecules from the ER is required for efficient presentation to T-cells of peptides generated by processing of exogenous proteins. This requirement does not contradict the hypothesis that MHC class II/peptide complexes, after being expressed on the cell surface, may recycle to endocellular organelles allowing peptide exchange to take place[19,20]. □

Tyrosine phosphatase CD45 is essential for coupling T-cell antigen receptor to the phosphatidyl inositol pathway

STIMULATION of T lymphocytes through their antigen receptor (T-cell receptor; TCR) results in the activation of a tyrosine kinase[1,2] and the generation of phosphatidyl inositol (PtdIns)-derived second messengers[3–5]. Several reports have indicated that CD45, a haematopoetic cell-specific surface glycoprotein with tyrosine phosphatase activity in its cytoplasmic domain[6–10], is important in lymphocyte activation[11–14]. To examine the possibility that CD45 might influence proximal signal transduction events through the TCR, we have isolated a variant of the human T-cell leukaemic line, HPB-ALL, which fails to express this phosphatase. Unlike cells expressing CD45, stimulation of the TCR in the CD45-negative cell does not result in PtdIns-derived second messengers. Reconstitution of CD45 expression restored early signalling events through the TCR. To localize the site of CD45 action, the human muscarinic type 1 receptor, which also activates the PtdIns second messenger pathway[15,16], was transfected into the CD45-negative cell. Although stimulation of the TCR failed to generate PtdIns-derived second messengers, there was normal activity of the PtdIns pathway when human muscarinic receptor type 1 was stimulated, despite the absence of CD45. These data indicate that CD45 influences a cellular component that is essential for effective coupling of the TCR to the PtdIns second messenger pathway.

We screened a number of human T-cell leukaemic lines for surface expression of CD45. One of the lines screened, HPB-ALL, stained heterogeneously with a panel of monoclonal antibodies (mAb) directed against CD45. Subcloning resulted in the isolation of several CD45-negative and CD45-positive HPB-ALL variants. Figure 1*a–d* shows flow cytometry histograms of representative isolates of these cells stained for surface expression of the TCR complex and CD45. In contrast to a previously described mutant cell line deficient in CD45 surface expression[11], northern blot analysis revealed no messenger RNA for CD45 in our negative variant, HPB.45.0 (data not shown). HPB.45.0 expresses significantly more TCR than does the CD45-positive variant, HPB.45.1 as assessed with anti-CD3 mAb.

We next examined the possible role of the CD45 tyrosine phosphatase in early events associated with TCR-mediated signal transduction. The ability of anti-CD3 mAb to activate the PtdIns signal transduction pathway was evaluated by measuring changes in cytoplasmic free Ca^{2+} ($[Ca^{2+}]_i$) (Fig. 2). In HPB.45.1, the cell expressing CD45, a rapid and large increase in $[Ca^{2+}]_i$ was seen in response to the activating anti-CD3 mAb, Leu 4 (Fig. 2*b*), similar to increases in $[Ca^{2+}]_i$ previously reported for HPB-ALL and other T cells[3,17,18]. By contrast, no detectable increase in $[Ca^{2+}]_i$ was observed in the CD45-negative cell HPB.45.0 (Fig. 2*a*), even though this cell expresses over an order of magnitude more TCR than the CD45-positive cell. That the cells were adequately loaded with the calcium-sensitive fluor, Indo-1, was shown by the response to the calcium ionophore, ionomycin.

The increase in $[Ca^{2+}]_i$ seen after stimulation of the TCR is due to the generation of soluble inositol phosphates by the hydrolysis of phosphatidyl inositol 4,5-bisphosphate ($PtdIns(4,5)P_2$) (refs 4, 19). We therefore studied the ability of anti-CD3 mAb to induce $PtdIns(4,5)P_2$ breakdown in the CD45-negative and -positive cells. Figure 3 depicts the result of such an experiment where inositol phosphates were measured at various times after anti-CD3 stimulation of HBP.45.0 and HPB.45.1. As expected from the observed increases in $[Ca^{2+}]_i$, the CD45-positive cells consistently generated an increase in soluble inositol phosphates, whereas the CD45-negative cells showed no such response.

Because activating stimuli alter expression of CD45 in T cells[20], we tested the effect of phorbol myristyl-13-acetate (PMA) treatment on CD45 levels in the CD45-negative cells. Following 24 h of PMA incubation, there was low but detectable induction of expression of CD45, peaking at ~48 h (Fig. 1*e*, *f*), and correlating with induction of CD45 mRNA (data not shown). To our knowledge, this is the first example of induction of the CD45 gene due to an external stimulus. The PMA-treated cells were stimulated with anti-CD3 mAb and analysed for increases in $[Ca^{2+}]_i$. Figure 2*c* shows a rapid and sustained increase in $[Ca^{2+}]_i$ seen in response to the Leu 4 mAb in PMA-treated HPB.45.0 cells. As expected, analysis of soluble inositol phosphates after anti-CD3 stimulation revealed substantial increases in the PMA-treated cells (data not shown). Similar studies with the CD45-positive HPB.45.1 cells revealed that PMA induced an increase in CD45 expression and a corresponding increase in PtdIns turnover (data not shown).

To demonstrate more directly that the defect in PtdIns response in the HPB.45.0 is due to its failure to express CD45, we transfected the CD45-negative HPB.45.0 cell line with a murine complementary DNA clone encoding CD45 (ref. 21). The intracellular portions of murine and human CD45, including the tyrosine phosphatase regions, are 85% homologous[22]. Although we have been unable to attain levels of murine CD45 expression comparable to levels of human CD45 observed in the CD45-positive HPB.45.1, several transfected clones do express low levels of murine CD45. Of these, several independent clones have been tested for responsiveness to anti-CD3 mAb. In each case, CD45-positive clones such as HPB.45.0 m45 (Fig. 2*d*; surface staining characteristics shown in Fig. 1*g*, *h*) show a significantly greater increase in $[Ca^{2+}]_i$ than does the CD45-negative HPB.45.0 host (Fig. 2*a*). Thus, even at low levels of expression of murine CD45, substantial restoration of the $[Ca^{2+}]_i$ response was observed.

To begin to localize the site of action of CD45 in regulation of the PtdIns second messenger pathway in human T cells, we examined the function of a heterologous receptor, the human muscarinic receptor type 1 (HM1), in T cells which do not express CD45. This receptor, which is not expressed in human T cells, can activate the PtdIns pathway[15,16,23]. HPB.45.0 was transfected with HM1 and a positive line, HPB.45.0.HM1, was identified by ^{3}H-quinuclidinyl benzylate (a muscarinic antagonist) binding (data not shown). This cell continued to express the TCR and failed to express CD45 (Fig. 1*i*, *j*) The ability of the transfectant to increase $[Ca^{2+}]_i$ in response to stimulation of both HM1 and the TCR was compared with the non-transfected parent and to a Jurkat line transfected with HM1, J-HM1-2.2, which is TCR- and CD45-positive (Fig. 1*k*, *l*). Neither the

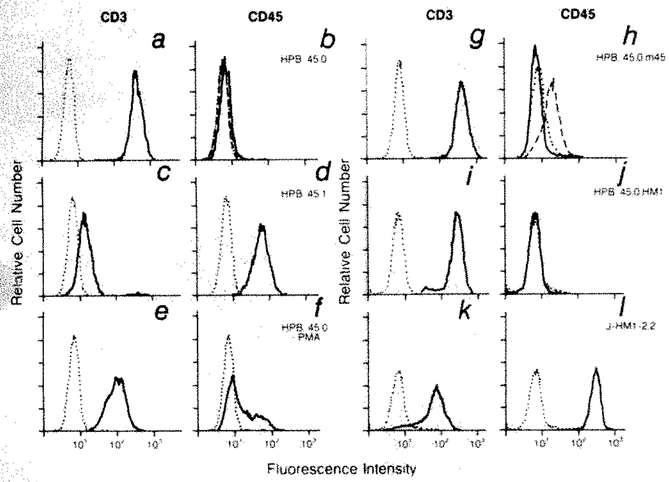

FIG. 1 Surface expression of TCR, human CD45 and murine CD45 on various human T cells. HPB.45.0 (*a*, *b*) and HPB.45.0 · m45 (*g*, *h*) were stained with a control mouse IgG (dotted line); anti-CD3 (Leu4, solid line); anti-human CD45 (HLE, directed against a common determinant of all isoforms of human CD45, solid line); and anti-murine CD45 (M1/9.3.4.HL.2, dashed line). HPB.45.1 (*c*, *d*); HPB.45.0 treated with PMA (Sigma), 50 ng ml^{-1} (48 h; *e*, *f*); HPB.45.0.HM1 (*i*, *j*), and J-HM1-2.2 (*k*, *l*) were stained with control IgG, anti-CD3, and anti-human CD45.

METHODS. Cells were stained as previously described[26]. Antibodies were from Becton-Dickinson except for M1/9.3.4.HL.2 which was from the ATCC, and FITC-conjugated second antibody from Caltag. Analyses were performed on a FACSCAN flow cytometer (Becton-Dickinson) using FACSCAN research software. HPB.45.0 (CD45-negative) and HPB.45.1 (CD45-positive) are clones obtained after limiting dilution of HPB-ALL. HPB.45.0 was transfected with cDNAs for murine CD45 (ref. 21) or HM1 (ref. 16) in expression vectors, by electroporation and selection for G418 resistance as described[16], generating HPB.45.0.m45 and HPB.45.0.HM1. J-HM1-2.2 is a Jurkat derivative expressing HM1 (ref. 16).

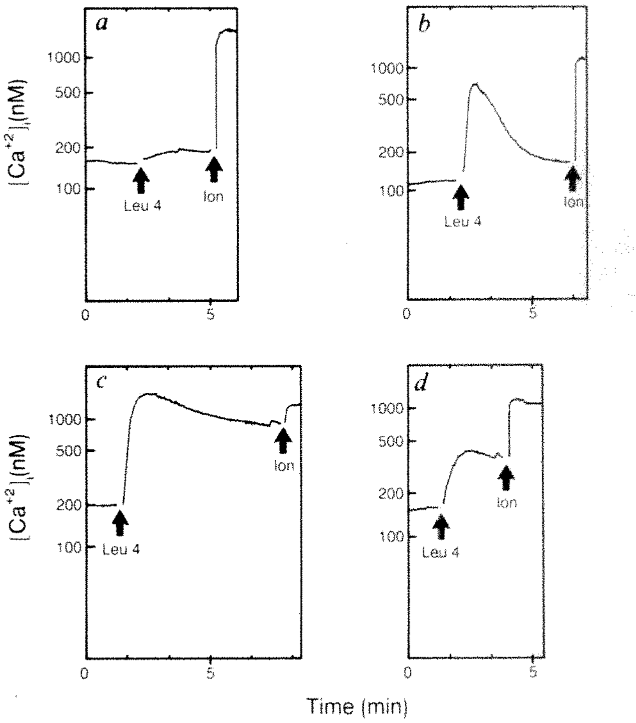

FIG. 2 $[Ca^{+2}]_i$ after stimulation of CD45-negative and CD45-positive derivatives of HPB-ALL. HPB.45.0, CD45-negative (*a*), HPB.45.1, CD45-positive (*b*), HPB.45.0 treated with PMA (50 ng ml^{-1} for 48 h, CD45-positive (*c*), and HPB.45.0.m45, murine CD45-positive (*d*).

METHODS. Each cell type was loaded with 3 μm Indo-1 (Molecular Probes) for 40 min as described[27]. Real time fluorescence was measured at 37 °C with excitation at 334 nm and emission detection at 400 nm in a spectrofluorimeter (Spex Industries). Anti-CD3 mAb (Leu 4) ascites was added (arrow) at a final concentration of 1:1,000 (a saturating amount), ionomycin (Calbiochem) was added at a final concentration of 1 μm. Maximal fluorescence was obtained after lysis of the cells with Triton X-100, minimal fluorescence was obtained after chelation with EGTA. $[Ca^{2+}]_i$ was determined as described[28].

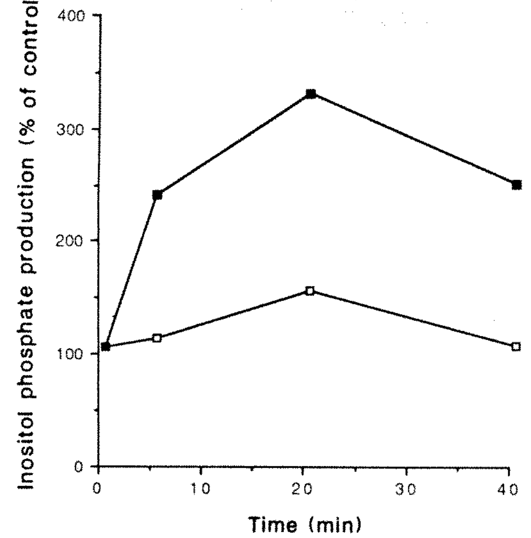

FIG. 3 Time course of soluble inositol phosphate generation in the CD45-negative (□) and CD45-positive (■) cell following TCR stimulation. METHODS. HPB.45.0 (CD45-negative) and HPB.45.1 (CD45-positive) were loaded with [^{3}H]*myo*-inositol (Amersham), 40 μCi ml^{-1} for 3 h in phosphate buffered saline then cultured in RPMI 1640 with 10% FCS (16 h) (ref. 16). The cells were then stimulated with anti-CD3 mAb (Leu 4 ascites, 1:1,000 final concentration) in the presence of 10 mM LiCl. At various time points the cells were lysed and soluble inositol phosphates extracted as described[16]. Data points represent means of duplicates.

muscarinic agonist, carbachol, nor the anti-CD3 mAb elicited a calcium response in the untransfected HPB.45.0 (data not shown). Carbachol induced a brisk calcium increase in J-HM1-2.2, that was reversed with the muscarinic antagonist, atropine. The cells were fully capable of then responding to stimulation via the TCR, as illustrated by the calcium increase seen after addition of mAb (Fig. 4*a*). Figure 4*b* shows that the CD45-negative cell which expresses HM1 also responds to carbachol with a rapid increase in $[Ca^{2+}]_i$, that was antagonized by atropine. Addition of activating mAb to the TCR, however, elicited no increase in $[Ca^{2+}]_i$. Thus, expression of HM1 did not restore TCR-mediated signal transduction function. Assays for the generation of soluble inositol phosphates in these cells resulted in comparable results, such that stimuli inducing $[Ca^{2+}]_i$ increases also elicited increases in inositol phosphates (data not shown).

These data indicate that effective coupling of the TCR to the PtdIns second messenger pathway requires the presence of CD45. The action of CD45 seems to be specific to the TCR activation of the PtdIns second messenger pathway, because in the absence of CD45 the HM1 receptor is fully functional. Although the exact role of CD45 remains to be identified, several studies suggest that this molecule is important in lymphocyte activation[11-14]. Additionally, tyrosine phosphatase activity of CD45 suggests potential interactions with the ζ-chain of the CD3 complex which becomes tyrosine-phosphorylated upon T-cell activation[24] or with Lck, a T-cell-specific tyrosine kinase of the *Src* family whose activity is modified by the presence or absence of CD45 (refs 9, 10). These results provide a potential link between the tyrosine kinase and PtdIns second messenger pathways associated with the TCR in human T cells. Our data, combined with a report of signalling-deficient T cells that are constitutively phosphorylated on CD3 (ref. 25), suggest that CD45 may have an essential role in the control of ζ-chain phosphorylation, which in turn regulates the ability of the TCR to activate the PtdIns pathway in response to stimuli.

Note added in proof: We have recently isolated CD45-negative mutants of the Jurkat T-cell line which are matched for TCR levels when compared with wild-type cells. These CD45-negative cells also fail to increase PtdIns-derived second messengers when stimulated via the TCR. □

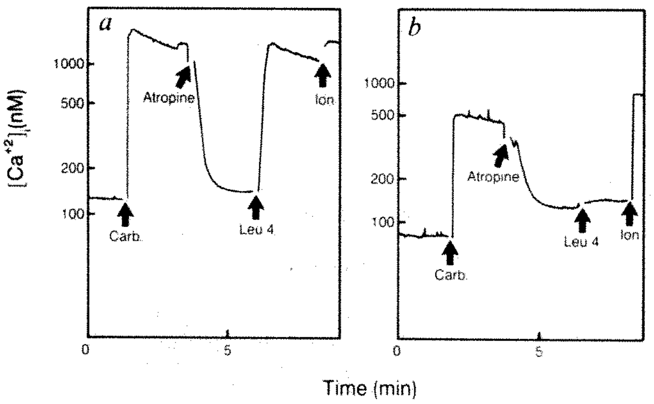

FIG. 4 $[Ca^{+2}]_i$ levels seen after stimulation of the HM1 or TCR in J-HM1-2.2 (*a*) and HPB.45.0.HM1 (*b*.) The assay was performed as in Fig. 2. Carbachol (Sigma) was used at a final concentration of 500 μm and atropine (Sigma) was used at a final concentration of 10 μm.

Hyperpolarization and relaxation of arterial smooth muscle caused by nitric oxide derived from the endothelium

M. Tare, H. C. Parkington*, H. A. Coleman, T. O. Neild & G. J. Dusting†

Department of Physiology, Monash University, Clayton,
Victoria 3168, Australia

STIMULATION of the endothelial lining of arteries with acetylcholine results in the release of a diffusible substance that relaxes and hyperpolarizes the underlying smooth muscle[1–9]. Nitric oxide (NO) has been a candidate for this substance, termed endothelium-derived relaxing factor[10,11]. But there are several observations that argue against the involvement of NO in acetylcholine-induced hyperpolarization. First, exogenous NO has no effect on the membrane potential of canine mesenteric arteries[7]. Second, although haemoglobin (believed to bind and inactivate NO (refs 11–15)) and methylene blue (which prevents the stimulation of guanylate cyclase[11–16]) inhibit relaxation[7,12–14], neither has an effect on hyperpolarization[5,7,8]. Finally, nitroprusside, thought to generate NO in vascular smooth muscle[14,16], relaxes rat aorta without increasing rubidium efflux[17]. Nevertheless, nitrovasodilators, nitroprusside and nitroglycerine cause hyperpolarization in some arteries[18–20]. NO might therefore be responsible for at least part of the hyperpolarization induced by acetylcholine. We now report that hyperpolarization and relaxation evoked by acetylcholine are reduced by N^G-monomethyl-L-arginine, an inhibitor of NO biosynthesis from L-arginine[21–25]. Thus NO derived from the endothelium can cause hyperpolarization of vascular smooth muscle, which might also contribute to relaxation by closing voltage-dependent calcium channels. Our findings raise the possibility that hyperpolarization might be a component of NO signal transduction in neurons or inflammatory cells.

Ring segments of guinea-pig uterine artery were prepared for simultaneous recording of membrane potential and tension development. Phenylephrine (10^{-8}–10^{-5} M) was used to depolarize the membrane and to raise tension (Fig. 1*a*). Infusion of NO caused hyperpolarization and relaxation (Fig. 1*b*). Concentration-response curves to NO-induced (3.6×10^{-8} M–3.6×10^{-5} M) hyperpolarization and relaxation were constructed for segments depolarized by 6 ± 0.5 mV ($n = 25$; Fig. 2). The effector concentration for half-maximum response (EC_{50}) for NO was 1.0×10^{-6} M for the relaxation, and 2.4×10^{-6} M for the hyperpolarization. If, in some arteries, there was a large difference in the doses at which the two responses occurred, this could explain why other studies have reported relaxation in response to NO without detectable hyperpolarization. In uterine arteries, relaxation occurred at the lowest doses of NO without hyperpolarization. At higher levels of depolarization, the maximum relaxation was always accompanied by hyperpolarization, suggesting that the hyperpolarization makes a greater contribution to relaxation when calcium influx is high.

Because NO can evoke hyperpolarization in the uterine artery, we examined whether NO of endothelial origin might account for some of the hyperpolarization in response to acetylcholine. Hyperpolarization and relaxation of uterine arteries in response to acetylcholine were both reduced to a similar extent by N^G-monomethyl-L-arginine, NMMA (2×10^{-5} M, Fig. 3), which reduces endothelium-dependent relaxation in blood vessels[22,23,25]. NMMA significantly reduced hyperpolarization and relaxation of uterine arteries by 41 ± 7% and 50 ± 6%, respectively ($n = 10$; Fig. 3*b*). L-Arginine (10^{-4} M) completely prevented the inhibition caused by NMMA (2×10^{-5} M; Fig. 3*c*). NMMA also reduced acetylcholine-induced hyperpolarization in mesenteric and coronary arteries of guinea-pigs. Thus, endothelium-derived relaxing factor (EDRF) is capable of

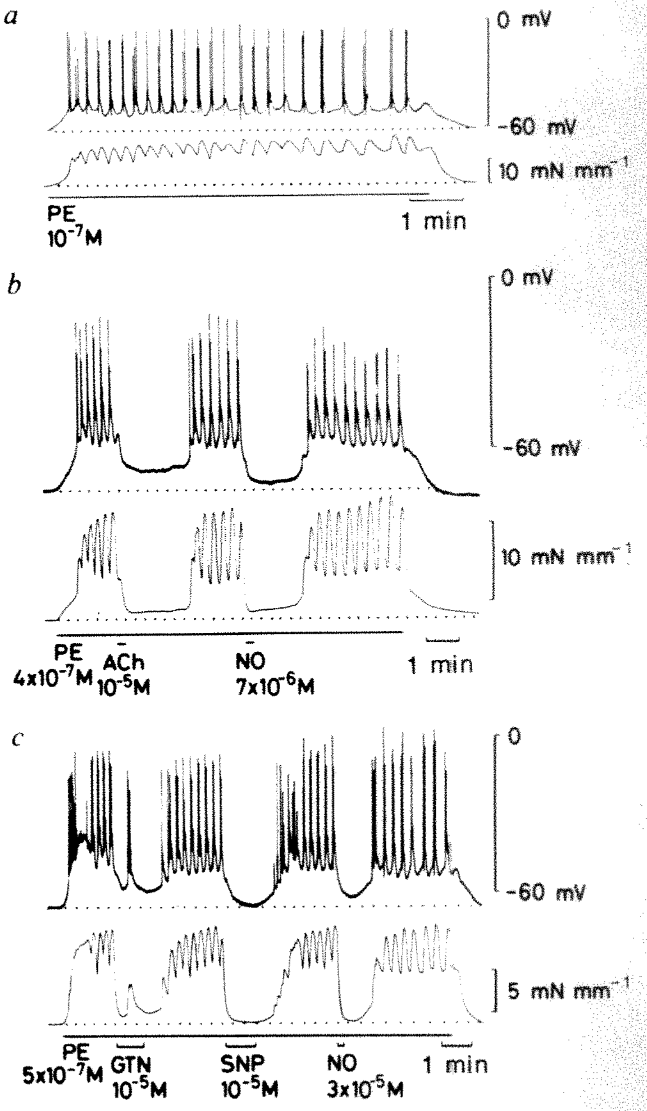

FIG. 1 Acetylcholine, NO and the nitrovasodilators cause hyperpolarization and relaxation of uterine artery. *a*, When the depolarization (upper trace) in response to phenylephrine (PE) was in the range −52 ± 1 mV and −41 ± 1 mV ($n = 22$), oscillations occurred in membrane potential, often topped with action potentials. Each oscillation was followed by a phasic increase in tension (lower trace). *b*, Application of acetylcholine to a vessel depolarized (upper trace) and constricted (lower trace) caused hyperpolarization and relaxation and these responses were mimicked by NO. *c*, Glyceryl trinitrate (GTN) and sodium nitroprusside (SNP) evoked hyperpolarization (upper trace) and relaxation (lower trace) that were similar to those caused by NO.
METHODS. Ring segments (1–2 mm in length) of uterine arteries from guinea-pigs were mounted on a Mulvany–Halpern-style myograph[29] with two stainless steel wires 40 μm in diameter, and continuously perfused with physiological solution containing: NaCl, 120 mM; KCl, 5 mM; KH_2PO_4, 1 mM; $NaHCO_3$, 25 mM; $MgSO_4$, 1.2 mM; $CaCl_2$, 2.5 mM; and glucose, 11 mM; gassed with 95% O_2, 5% CO_2 and maintained at 35 °C. Each segment was stretched in increments until the tension was equivalent to 60–65 mmHg. Membrane potential was measured simultaneously. Solutions of NO were made from NO gas dissolved in deoxygenated water and introduced into the perfusion line with a delay of 1–2 s between the point of injection and the preparation.

TABLE 1 Effect of membrane potential on hyperpolarization and relaxation in uterine arteries of guinea-pigs

Resting membrane potential (mV)	Membrane potential (mV) in phenylephrine	% Hyperpolarization		% Relaxation	
		ACh (10^{-5} M)	NO (2.5×10^{-5} M)	ACh (10^{-5} M)	NO (2.5×10^{-5} M)
−69 ± 1 (41)	−64 ± 1 (23)	84 ± 10 (13)	114 ± 11 (10)	118 ± 12 (13)	126 ± 5 (10)
	−29 ± 1 (16)	13 ± 5 (9)	27 ± 4 (7)	14 ± 4 (9)	40 ± 8 (7)

Arteries were exposed to phenylephrine (5×10^{-8} to 5×10^{-7} M) and (5×10^{-7} to 5×10^{-5} M) that depolarized the smooth muscle cells to −64 mV and −29 mV, respectively. Hyperpolarization and relaxation are expressed as percentages of the depolarization and constriction, respectively, induced by phenylephrine. Values of *n* are given in parentheses. ACh, acetylcholine.

contributing to this hyperpolarization in these vessels. Because both hyperpolarization and relaxation were not completely abolished, it is possible that another mechanism contributes to the hyperpolarization and relaxation in response to acetylcholine.

Exposure of uterine arteries to methylene blue (10^{-5} M) for 15–20 min before addition of phenylephrine caused depolarization and tension development. In the presence of methylene blue and phenylephrine, the concentration-response curves to NO for both hyperpolarization and relaxation were shifted to the right. After prolonged exposure to methylene blue, both hyperpolarization and relaxation were abolished (Fig. 2*a*, *b*). Both hyperpolarization and relaxation in response to acetylcholine were reduced or abolished after incubation in methylene blue ($n = 5$). Exposure to 10^{-5} M haemoglobin for 10 min before and during application of phenylephrine resulted in abolition of NO-induced hyperpolarization and relaxation (Fig. 2*a*, *b*). Haemoglobin also reduced relaxation in response to acetylcholine in each of seven preparations. In three of these the hyperpolarization was also reduced, but it remained unchanged in the remaining four.

The ability of NO to hyperpolarize uterine arteries might have reflected properties unique to these arteries, but we found that NO hyperpolarized and relaxed all other vessels studied: phenylephrine-depolarized mesenteric ($n = 12$), mammary ($n = 3$) and saphenous ($n = 1$) arteries and aorta ($n = 1$) of guinea-pigs; tail arteries from rats ($n = 3$); saphenous ($n = 1$) and femoral ($n = 1$) arteries from rabbit; mesenteric arteries from dogs ($n = 2$) and guinea-pig coronary arteries at rest ($n = 15$). The ability of some arteries to respond to NO declined with repeated application. That is, there was tachyphylaxis of both the hyperpolarization and relaxation, and the hyperpolarization usually disappeared before the relaxation.

Nitroprusside and nitroglycerine are thought to cause relaxation by liberating NO in smooth muscle cells[14,16]. These nitrovasodilators evoke hyperpolarization in some vascular smooth muscles[18-20] but are without effect on others[17,26-28]. In six uterine arteries depolarized by 7 ± 1 mV and constricted by 1.7 ± 0.3 mN mm^{-1} with phenylephrine (8×10^{-8}–2×10^{-6} M), sodium nitroprusside (10^{-5} M) and nitroglycerine (10^{-5} M) caused hyperpolarization of 138 ± 16% and 110 ± 8%, respectively, accompanied by relaxation of 128 ± 9% and 117 ± 8%, respectively (Fig. 1*c*). In contrast to the actions of acetylcholine, the actions of NO and the nitrovasodilators were independent of the integrity of the endothelium. The nitrovasodilators could hyperpolarize rat tail arteries, but only in those preparations in which the resting membrane potential was more depolarized than −70 mV (ref. 19). NO and acetylcholine could not hyperpolarize uterine arteries that were not depolarized by phenylephrine. These arteries have a high negative resting membrane potential (−69 ± 1 mV, $n = 41$), compared with mesenteric and coronary arteries (−61 ± 2 mV ($n = 12$) and −58 ± 2 mV ($n = 15$), respectively), and in none of these arteries could acetylcholine or NO hyperpolarize the membrane beyond about −70 mV.

The hyperpolarization in response to acetylcholine is due to an increase in potassium conductance[2,3,8]. When the potassium concentration in the perfusing solution was raised (10–100 mM), the hyperpolarization induced by both acetylcholine and NO in uterine arteries was reduced or abolished. Others have shown that the ability of acetylcholine to induce hyperpolarization and relaxation is dependent on the extent of depolarization elicited by the raised external potassium. At large depolarizations, there is a reduction in amplitude of both the hyperpolarization[2,8] and the relaxation[17]. It can be seen from Table 1 that the hyperpolarization and relaxation induced by acetylcholine (10^{-5} M) and NO (2.5×10^{-5} M) are also dependent on the extent of depolarization induced by phenylephrine in uterine arteries. Thus, there is a range of membrane potential in which NO can

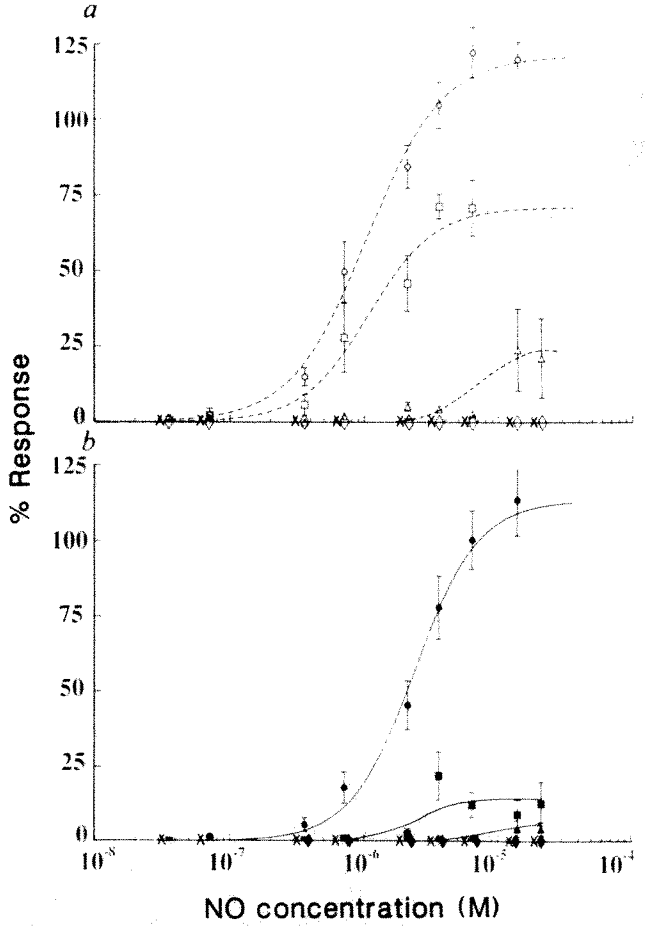

FIG. 2 Dose-dependent hyperpolarization of the membrane and relaxation evoked by NO in uterine arteries of guinea-pigs. *a*, Relaxation (open symbols). *b*, Hyperpolarization (filled symbols). The arteries were exposed to concentrations of phenylephrine (10^{-8}–5×10^{-6} M) that depolarized the smooth muscle by 6 ± 0.5 mV and raised tension by 4 ± 0.4 mN mm^{-1}. Concentrations of NO (4×10^{-8}–4×10^{-5} M) were applied and the hyperpolarization and relaxation that resulted expressed as a percentage of the phenylephrine-induced depolarization and increase in tension, respectively. NO evoked concentration-dependent relaxation (*a*) and hyperpolarization (*b*) in uterine arteries (circles; $n = 24$). Methylene blue (10^{-5} M) caused time-dependent inhibition of both relaxation ($n = 10$) and hyperpolarization ($n = 9$; squares, 21 min; triangles, 53 min; diamonds, 81 min). Both responses were abolished after 81 min. Exposure to haemoglobin (10^{-5} M) abolished the responses (crosses; $n = 7$). Vertical bars represent standard errors of the mean. The number of animals studied (*n*) (not the number of cells impaled) is used throughout.

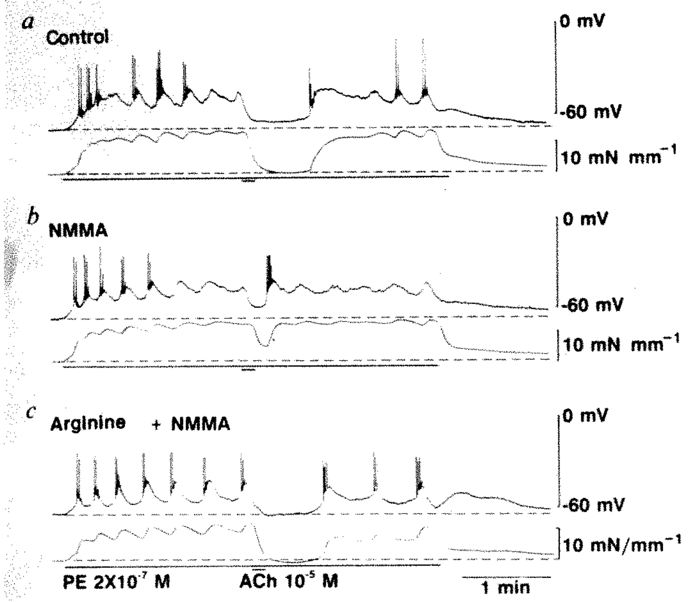

FIG. 3 Inhibition of acetylcholine-induced hyperpolarization and relaxation by L-NMMA. *a*, Hyperpolarization (upper trace) and relaxation (lower trace) evoked by 10^{-5} M acetylcholine in a uterine artery depolarized and constricted with phenylephrine (PE). *b*, Preincubation of the tissues with NMMA acetate (2×10^{-5} M) reduced the amplitude and duration of the hyperpolarization and relaxation in response to 10^{-5} M acetylcholine. *c*, The effect of this concentration of NMMA was antagonized by 10^{-4} M L-arginine, added during and for 10 min before application of NMMA.

cause hyperpolarization. The more negative potentials are close to the equilibrium potential for potassium, whereas at substantial levels of depolarization, the magnitude of total conductance swamps NO-induced potassium conductances. The level of membrane potential in determining the ability of acetylcholine and NO to elicit hyperpolarization may explain why others have failed to find an effect of NO on membrane potential. Moreover, in our study membrane potential and developed tension have been measured simultaneously in the same tissue.

In conclusion, NO, whether derived from the endothelium as EDRF or from nitrovasodilator drugs, can mediate hyperpolarization of arterial smooth muscle. Although NO can induce relaxation by stimulation of calcium extrusion alone, the contribution of the hyperpolarization to relaxation is probably more important when calcium influx is high. ☐

Subsecond deactivation of transducin by endogenous GTP hydrolysis

T. Minh Vuong*[*] & Marc Chabre*

Laboratoire de Biophysique Moléculaire et Cellulaire,
(Unité Associée 520 du CNRS) Centre d'études Nucléaires de Grenoble,
BP 85X, F-38041 Grenoble, France

THE response of a retinal rod cell to a weak flash of light is mediated by a receptor/GTP-binding protein (rhodopsin/transducin) signal transduction system[1,2] and terminates within a second[3]. The Tα subunit of transducin (composed of subunits Tα, Tβ and Tγ) is triggered by photoexcited rhodopsin (R*) to release GDP and bind GTP. The binding of GTP causes release of the Tα unit from Tβγ and allows it to modulate the activity of an enzyme that generates a second messenger. Termination of the response requires the hydrolysis of the GTP by intrinsic GTPase[4,5]. As with other G proteins, the GTPase activity of transducin seems to be slow. Reported *in vitro* turnover rates of a few molecules of GTP hydrolysed per molecule of transducin per minute[6–9] imply a Tα-GTP deactivation time of many seconds. But this time might be only a small fraction of that of the GTPase cycle. We have now used time-resolved microcalorimetry[10–12] in bovine rod outer segments (ROS) to monitor the heat release due to the hydrolysis of GTP by a transducin population that had been quickly activated by flash illumination of rhodopsin. The enthalpy of GTP hydrolysis is released within 1 s at 23 °C. This deactivation time seems to be independent of any diffusible factor in the preparation and concurs with the termination kinetics of the rod's response. Thereafter, transducin seems unable to reload GTP for many seconds. This refractory 'resetting' time may account for the low steady-state GTPase rates *in vitro*.

In vitro steady-state measurements of the GTPase rate of transducin under continuous illumination (a condition for receptor saturation) assay a complete cycle that includes[13] encounter of Tα-GDP-Tβγ with photoexcited rhodopsin, R*-catalysed GDP/GTP exchange on Tα, dissociation of active Tα-GTP from R* and Tβγ, deactivation by endogenous GTP hydrolysis, and reassociation of Tα-GDP with Tβγ before a new cycle can begin. The first three steps determine the millisecond activation time of transducin[14], whereas the hydrolytic step determines the deactivation time. Any other steps such as a long-lived post-hydrolytic GDP-Pi conformation (as with tubulin or actin) or a slow re-association of Tα-GDP with Tβγ will lengthen the GTPase cycle.

Whereas steady-state techniques necessarily give a sum total of these times, they may be separated by a time-resolved technique applied to a transiently activated sample.

Under weak flash illumination, fast quenching of R* is achieved *in vivo* by the combined action of rhodopsin kinase and arrestin[15], the latter taking <0.2 s to bind to phosphorylated R* (ref. 16). *In vitro*, this quenching takes seconds even with kinase and arrestin enrichment of concentrated ROS suspensions[15,17]. If needed, however, hydroxylamine can be used to accelerate the deactivation of R* by displacing its retinal[18].

---

[*] Present address: Institut de Pharmacologie du CNRS, 660 route des Lucioles, Sophia Antipolis, F-06560 Valbonne, France.

Most of the enthalpy of GTP hydrolysis is released in three steps: R*-catalysed GTP loading and associated transconformation of Tα; hydrolysis of Tα-GTP to Tα-GDP per se; and reassociation of Tα-GDP with T$\beta\gamma$. So the kinetics of this enthalpy release constitutes an upper-bound of the Tα-GTP lifetime. We assessed the enthalpy release using a custom-designed time-resolved microcalorimeter (Fig. 1), on flash-illuminated ROS suspensions. With the addition of both GTP and cyclic GMP (Fig. 2*a*) there arises a large signal resulting mainly from the amplified hydrolysis of cGMP by the activated cGMP phosphodiesterase (cGMP-PDE). Hydrolysis of known amounts of cGMP provides an internal calibration of the cell's thermal sensitivity (Fig. 2*b*). With the addition of GTP only, a smaller signal due to light-induced GTP hydrolysis (Fig. 3*a*) is observed. It follows a fast spike due to heating by the absorbed light flash that is also seen alone in the absence of GTP or after its exhaustion (Fig. 3*c*). The signal with only GTP present is not due to contaminant cGMP as the preparations used have in the dark a nonspecific PDE[19] that is more active than the guanylate cyclase (Fig. 2*b*).

The GTP hydrolysis signal almost saturates at $R^*/R = 2.6 \times 10^{-4}$ (Fig. 3*b*), where the integrated amplitude of the signal roughly corresponds to one turnover of the transducin pool (using a ΔH value of 5-6 kcal mol^{-1} for GTP hydrolysis, based on the ΔG value of 7.3 kcal mol^{-1} for ATP hydrolysis). At low levels of NH_2OH this hydrolysis signal displays a fast pulse component and a slow long tail (Fig. 3*a*, *g*). The rise time of the pulse component is about 0.3 s, its fall time about 0.6 s. With only 5 mM NH_2OH, R* lasts 6-10 s[18] during which it continuously catalyses the turnover of transducin. The pulse component in Fig. 3*a* thus corresponds to the first round of GTP hydrolysis by all the transducin that is ready before the light flash: immediately after illumination and once only, transducin is quickly activated and almost synchronously deactivated by GTP hydrolysis. Subsequently, and as long as some R* persists, transducin turns over. The rate of the heat release is then governed by the duration of the whole cycle which must include one or many slow steps as the long tail in Fig. 3*a* is much smaller than the pulse. Thus, if there is little NH_2OH, and some R* persists, transducin will recycle but the GTPase turnover rate will be limited by the slow 'resetting' steps. One might postulate a long-lived intermediate refractory Tα (Tα_{ref}) that still contains the γ-phosphate and/or is still soluble like Tα-GTP and thus cannot reassociate with T$\beta\gamma$. With 25 mM NH_2OH (Fig. 3*d*), one expects R* to decay faster, resulting in little or no transducin turnover and a concomitant reduction or disappearance of the tail component, which is indeed the case. As the R* lifetime should not kinetically influence transducin activation and

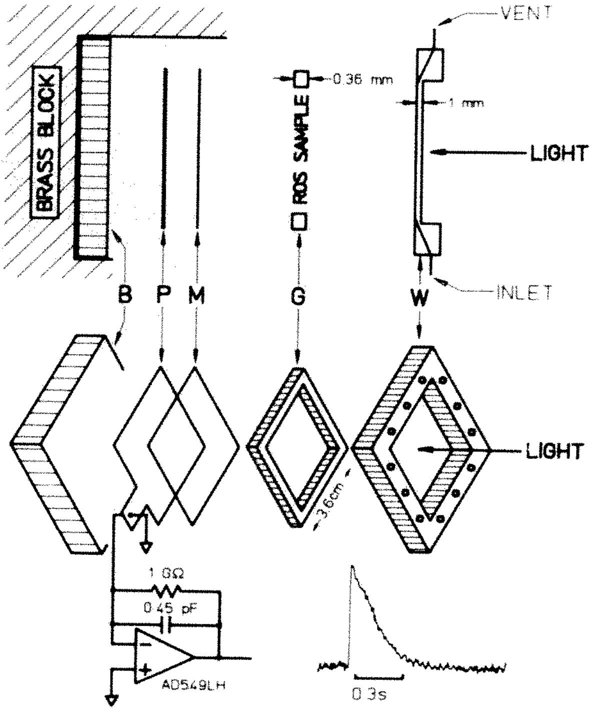

FIG. 1 The active element of the microcalorimeter is a 40-μm-thick poled, polyvinylidenefluoride (PVDF)[25] film gold-plated on both faces (P) (Solvay & Cie, Bruxelles). The back electrode is epoxy-glued to a thermally insulating slab (10-mm thick) of balsa wood (B) and the front electrode is protected from the liquid sample by a 6-μm mylar layer (M). A 0.36-mm-thick Parafilm gasket (G) and a Teflon window (W) define a 3.6 × 3.6-cm sample chamber. The film's grounded front electrode acts as a shield to the back electrode which is connected to the operational amplifier. The cell thus arranged is adiabatic. It is mounted together with the amplifier between two 15-kg blocks of brass (S) stabilized at 23 °C in a styrofoam box; the block in front has a double-paned window through which the sample can be illuminated. This instrument is an improved version of one described before[11]. Dilation from heating causes the PVDF polarizability to decrease, generating a displacement current proportional to the derivative of the film temperature[25]. The integral of this signal is proportional to the quantity of heat received by the film. This device thus monitors in real time the rate of reactions through their enthalpy release. The trace shown is the instrument's response obtained by flashing a dye solution. Direct heating of the PVDF by the light flash was accounted for by subtraction using the same procedure as in ref. 12.

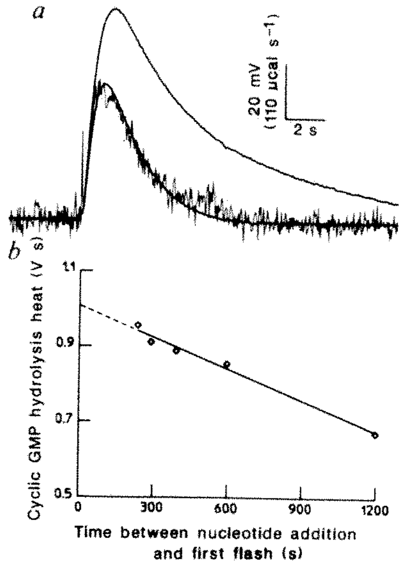

FIG. 2 Cyclic GMP hydrolysis signals and microcalorimeter calibration. *a*, Flash-induced cGMP hydrolysis in dilute ROS samples: 3.8 μm rhodopsin, 0.2 mM GTP, 3 mM cGMP, 0.5 mM NH_2OH (upper trace), 50 mM NH_2OH (lower thick trace) or 200 mM NH_2OH (lower thin trace, signal ×14 to normalize to that with 50 mM NH_2OH), flash photoexcitation $R^*/R = 5.2 \times 10^{-5}$. *b*, Calibration by cGMP hydrolysis in dilute samples (composition and photoexcitation as in *a*, lower thick trace). As there is a nonspecific PDE activity in the dark[19], samples were illuminated at different times after nucleotide addition by series of 20 flashes to exhaust the cGMP (GTP hydrolysis heat is $<10^{-3}$ times that of cGMP hydrolysis); the total hydrolysis heat from each sample is the sum of the integrated areas of these 20 signals. Using $\Delta H = 12.3$ kcal mol^{-1} (ref. 12) for cGMP hydrolysis, zero-time extrapolation of the linear fit through these sums gives a calibration value (1 mV.s = 5.5 μcal) about equal to that obtained from flash-heating a dye solution.

METHODS. Bovine ROS prepared as in ref. 26 and stored at −70 °C were resuspended into buffer in total darkness and incubated 20 min at 23 °C with 1 mM NH_2OH to scrub R* formed before or during preparation. This concentrated (150–250 μM rhodopsin) stock suspension was stored on ice until use. Adequate amounts of buffer, GTP, cGMP, NH_2OH (adjusted with KOH to pH 7.5), were added and the sample (0.46 ml) injected into the cell. Measurements were begun after 4–5 min to allow thermal equilibration with the cell. Buffer composition: 100 mM KCl, 20 mM HEPES, pH 7.5, 2 mM $MgCl_2$, 0.4 mM DTT.

deactivation, the width of the pulse in Fig. 3*d* is mostly identical to that of Fig. 3*a*. At still higher NH_2OH levels (50 mM, data not shown), R* is too short-lived to activate the whole transducin pool: the GTP hydrolysis pulse slightly decreases in amplitude while maintaining the same kinetics. This effect is also seen with the cGMP hydrolysis signal: with an increase in NH_2OH concentration from 0.5 to 50 mM, a long tail disappears, whereas with a change of 50 to 200 mM NH_2OH, signal amplitude decreases but there is no change in kinetics (Fig. 2*a*).

The kinetics of the GTP hydrolysis pulse is unchanged by a two fold dilution of the sample (Fig. 3*e*) and therefore seems independent of a soluble accelerating cofactor.

Double-flash experiments reveal a refractory time during which the GTP signal cannot be fully re-elicited. Recovery takes 4–8 s at 50 mM NH_2OH (Fig. 4*a–c*), more than 12 s at 10 mM NH_2OH (Fig. 4*d–e*) and 2 min at 2 mM NH_2OH (not shown). A high NH_2OH concentration quickly deactivates R*, and transducin activation ends soon after the flash. The 4–8-s refractory time is then the resetting time needed to replenish the Tα-GDP-Tβγ pool before another signal is possible. With little NH_2OH, R* and transducin activation persist after the flash: turnover occurs, governed by the slow resetting process. Hence, $T\alpha_{\text{ref}}$ and/or Tα-GDP accumulate, but the Tα-GDP-Tβγ pool is hardly replenished: a second flash elicits no signal (Fig. 4*d*); the longer refractory time at low NH_2OH concentration merely approximates the R* lifetime during which Tα-GDP-Tβγ is not replenished.

The R*-quenching effect of NH_2OH is not strictly required in demonstrating the fast kinetics of endogenous GTP hydrolysis, as the activation-deactivation times are much faster than the resetting time. This significant kinetic difference allows the separation of the two processes even when there is transducin turnover at low NH_2OH concentrations (Fig. 3*a*). High NH_2OH concentrations, when used in less crucial experiments, seem relatively harmless. As checked by the pH metric technique[20] on continuously illuminated samples, the saturated cGMP-PDE activity is not modified by addition of 50 mM NH_2OH (data not shown). Furthermore, hydroxylamine does not seem to accelerate transducin deactivation, as the GTP hydrolysis pulse does not speed up when the concentration of NH_2OH increases from 5 mM to 25 mM (Fig. 3*a*, *d*).

The *in vitro* kinetics of the transducin GTPase cycle thus include three or four steps: (1) activation, Tα-GDP-Tβγ → Tα-GTP + Tβγ, taking about 0.1 s; (2) deactivation, Tα-GTP → $T\alpha_{\text{ref}}$, completed within 1 s; (3) regeneration, $T\alpha_{\text{ref}}$ → Tα-GDP; and/or (4) reassociation: Tα-GDP + Tβγ → Tα-GDP-Tβγ, which may last many seconds.

Being in the subsecond range, endogenous GTP hydrolysis qualifies kinetically as a shut-off mechanism for visual transduction; its speed does not depend on soluble cofactors (contrary to refs 21 and 22), but transducin interaction with native disk membranes and, as suggested for other G proteins, a physiological ionic composition[23], might be crucial. The resetting time during which transducin cannot reload GTP accounts for the reported low steady-state GTPase rates. This could be an *in vitro* effect due partially to the solubilization of Tα-GTP causing a slow recombination of the resulting Tα-GDP to membrane-bound Tβγ. Although Gα-GTP subunits of other G proteins do not seem as soluble as Tα-GTP, their reported GTPase rates *in vitro* might also be poor indicators of their lifetimes *in vivo*

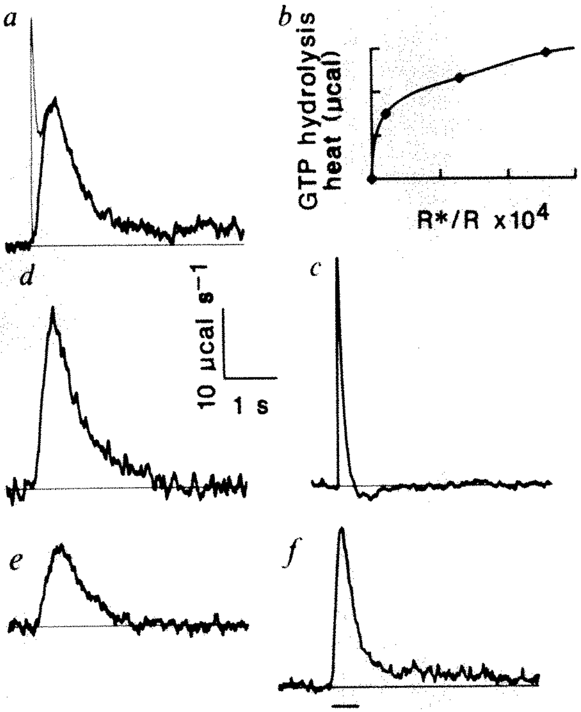

FIG. 3 Kinetics of GTP hydrolysis. *a*, Light-induced GTP hydrolysis signal at low NH_2OH: 63 µM rhodopsin, 2 mM GTP, 5 mM NH_2OH, $R^*/R = 1.3 \times 10^{-4}$ (thin trace). The spike preceding the broader signal is due to direct heating of the PVDF film by the light flash. *b*, Integrated areas (in µcal) of GTP hydrolysis signals as a function of photolysis levels: 75 µM rhodopsin, 2 mM GTP, 50 mM NH_2OH, $R^*/R = 2.2 \times 10^{-5}$, 1.3×10^{-4} and 2.6×10^{-4}. *c*, Average of eight flash spikes collected after GTP exhaustion; its subtraction from the raw signal reveals the heat generated by the sample itself (*a*, thick trace). The slight negative component is due to cooling of the PVDF film by the exhausted sample. *d*, *e*, GTP hydrolysis signals at higher NH_2OH from: 75 µM (*d*), 33 µM (*e*) rhodopsin, 2 mM GTP, 25 mM NH_2OH, $R^*/R = 1.3 \times 10^{-4}$. *f*, Average of two experiments at low NH_2OH levels (same composition and illumination as in *a*) shown on a ×2 compressed time scale. These GTP hydrolysis signals are repeatable up to 50 times. The signals in *a*, *d*, *e* and *f* come from samples of the same preparation. (The significant light-independent GTPase activity of these ROS samples adds only a constant to the baseline.)

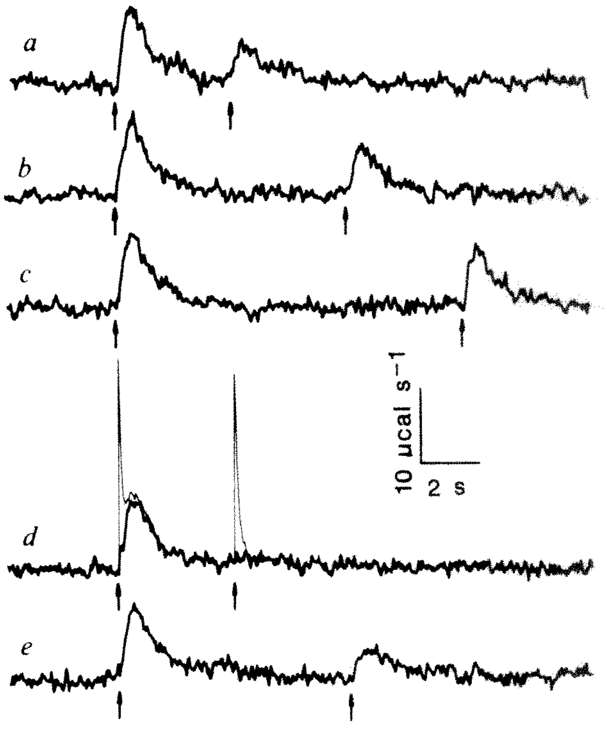

FIG. 4 Double-flash experiments. Varyingly spaced pairs of flashes (arrows, $R^*/R = 1.3 \times 10^{-4}$) from two aliquots containing 69 µM rhodopsin, 2 mM GTP, with 50 mM NH_2OH (*a–c*), or 10 mM NH_2OH (*d*, *e*). Each trace is an average of four (*a–c*) or two (*d*, *e*) recordings separated by 1–2 min. The flash spikes have been subtracted (as in Fig. 3*a*) except in *d* (thin trace) where both flash spikes can be seen in the unsubtracted data.

which control the duration of effector activation, and hence the integrated intensity of cellular responses. The recent demonstration that a mutated Gα with reduced GTPase activity is involved in cellular transformation[24] stresses the importance of an accurate knowledge of the true lifetime of Gα-GTP. ☐

THE fibrinolytic potential of the vasculature is modulated primarily by the availability and activity of plasminogen activators, which convert the zymogen plasminogen into the active fibrin-degrading enzyme plasmin[1]. The activities of these key regulatory enzymes are directly neutralized by their primary endogenous inhibitor, plasminogen activator inhibitor-1 (PAI-1)[2–6]. Although some individuals with a tendency to develop thrombotic disorders exhibit elevated levels of PAI-1 in their plasma[7–10], the cause-and-effect relationship between increased PAI-1 and thrombosis is still unclear. Specifically, it is not known whether chronic depression of fibrinolytic activity results in the development of thrombosis. To address this question we developed transgenic mice in which the contribution of PAI-1 to thrombus formation could be evaluated. The results presented in this report indicate that elevated levels of PAI-1 contribute to the development of venous but not arterial occlusions.

The DNA construct used in the production of PAI-1 transgenic mice contained the murine metallothionein I promoter, human endothelial cell PAI-1 complementary DNA, and the bovine growth hormone polyadenylation signal sequence. Mice putatively transgenic for human PAI-1 showed a single, early indication of disturbance of the haemostatic system (Fig. 1*a* and *b*). A distinct area of subcutaneous haemorrhage was apparent at the tip of the tails of mice at about 3 days after birth. This change became increasingly severe as the mice aged, until by ~12 days after birth the tip of the tail was necrotic and, in addition, the mice had swollen hind feet (Fig. 1*c*, right). At this age, no other changes were noted. Putative nontransgenic litter mates had normal tails and hind feet (Fig. 1*c*, left). The necrotic tails and swollen hind feet seemed to be the result of venous occlusions detected hisotologically (Fig. 1*e* and *f*). These occlusions were seen in pups as young as 3 days (the earliest histological examination) and were localized exclusively in the venous circulation; the arteries of the distal tail and limbs were patent. This localization is probably related to the observed haemorrhage and oedema. The thrombi consisted predominantly of mononuclear leukocytes, but also contained platelets, erythrocytes and fibrin. The presence of muscle degeneration and inflammation in 3-day-old mice indicates very early onset of the occlusive disorder, and may at least partially explain why cellular, as opposed to simply fibrin-platelet, thrombi were primarily detected. By ~2 weeks of age, the necrotic portion of the tails had completely sloughed off, whereas the swollen hind limbs appeared normal. This resolution of the occlusions in, and recovery of, the hind limbs of the mice may have been caused by compensatory mechanisms (for example, increased plasminogen activator expression) or by a decline in PAI-1 transgene expression. Therefore, the relationship between the time-dependent existence of the lesions and the levels of PAI-1 DNA, messenger RNA and protein was examined.

DNA extracted from the tails of mice displaying the circulatory disturbances described hybridized with a radiolabelled human PAI-1 cDNA probe, whereas DNA obtained from litter mates having normal tails or from control mice showed little or no hybridization (Fig. 2). Based on these results, 13 founder (G_0) animals were identified, having gene copy numbers of 1-10. In all instances, the existence of the venous occlusions correlated with the presence of the PAI-1 transgene. Assays for PAI-1 protein, activity, and mRNA were then used to correlate PAI-1

TABLE 1 PA1-1 DNA, mRNA and protein in tissues of transgenic mice

Phenotype (*a*)	Tissue					
	Spleen	Liver	Kidney	Heart	Brain	Lung
Control	ND	6.1	ND	0.8	0.1	0.1
Normal tail	5.8	6.9	8.0	1.1	1.1	0.2
Short tail	438.2	176.3	126.5	12.7	12.2	7.0

(*b*)	DNA			mRNA			Protein		
Age (days):	4	7	28	4	7	28	4	7	28
Control	0	0	0	<0.5	<0.5	<0.5	10	4	6
Normal tail	4	2	2	1.4	2.5	<0.5	11	10	9
Short tail	11	8	8	5.6	3.5	<0.5	210	98	21

a, Levels of PAI-1 protein in tissues obtained from 4-day-old control and G_1 and G_2 mice of differing phenotypes. Values are expressed as nanograms of PAI-1 per g wet weight of tissue. ND, not detectable. *b*, PAI-1 DNA copy number and levels of PAI-1 mRNA and protein in samples of liver tissue obtained from control and G_1 and G_2 transgenic mice of various ages. Messenger RNA values are expressed as pg per μg of total RNA and protein values are expressed as ng per g wet weight of tissue. Three to five animals were analysed in each group. DNA was prepared as described in Fig. 2. The DNA samples were then assayed by Southern blot analysis in which 10 μg was digested with restriction enzymes, electrophoresed in a 1.0% agarose gel, blotted onto nitrocellulose, and probed with radiolabelled PAI-1 cDNA. PAI-1 gene copy-number of the transgenic mice was determined using standard amounts of the injected transgene in parallel lanes of a Southern blot of the transgenic mouse genomic DNA. RNA was prepared as described in ref. 16 and measured spectrophotometrically. RNA preparations (10 μg) were denatured in 12 × SSC and 15% formaldehyde at 60 °C for 15 min. The denatured RNA was applied to nitrocellulose using a slot blot apparatus (Schleicher & Schuell) and baked at 80 °C *in vacuo*. The RNA samples were then probed with radiolabelled PAI-1 cDNA, and PAI-1 mRNA levels were determined by comparison to a PAI-1 mRNA standard curve generated from the PAI-1 cDNA in pBS using the T3 promoter. For PAI-1 protein determinations, tissues were weighed and then extracted in buffer containing 0.1% Triton X-100. After centrifugation of the extracts, the supernatant fluids were analysed for PAI-1 protein using a monoclonal antibody enzyme-linked immunosorbent assay (American Diagnostica).

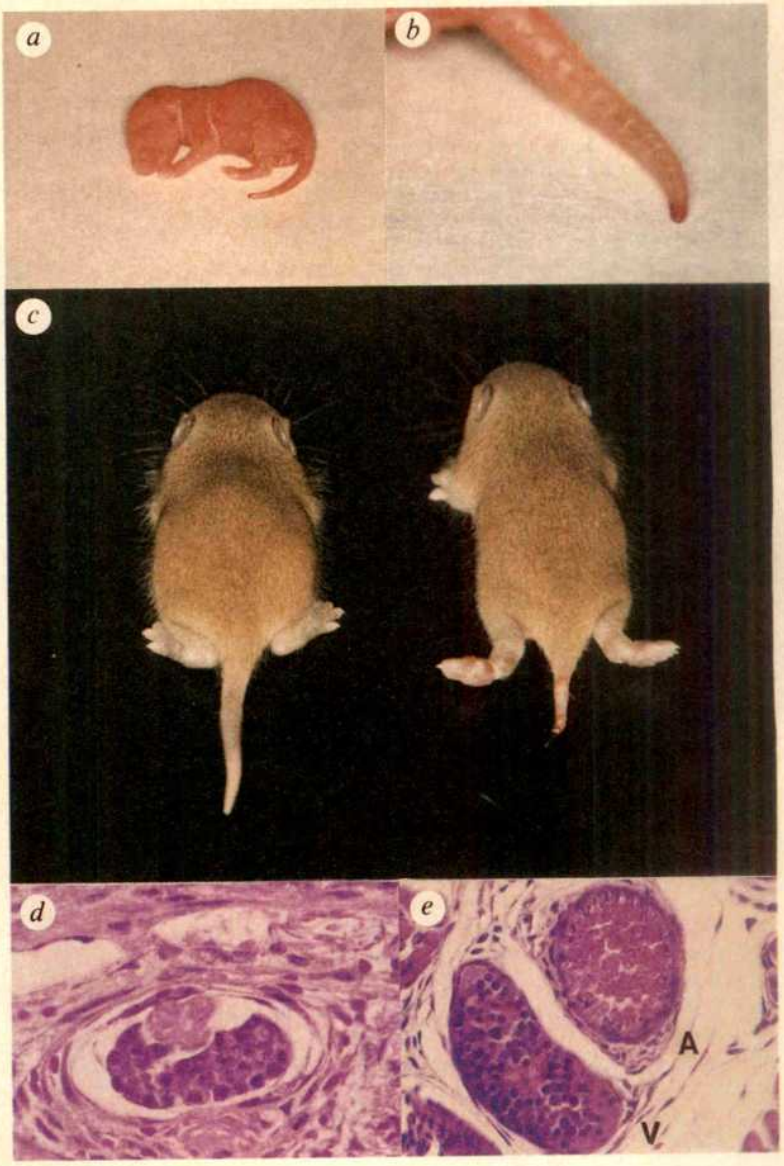

FIG. 1 Morphology and histological analysis of PAI-1 transgenic mice. *a*, Putative PAI-1 transgenic mouse photographed 3 days after birth. *b*, Higher magnification view of the tail region shown in *a*. *c*, Mice photographed 12 days after birth. Left, mouse with normal tail and hind feet; right, transgenic mouse showing necrosis and sloughing of the tail and swollen hind feet. *d*, Histological cross section through the tail vein of 7-day-old PAI-1 transgenic mouse with necrosis of the tail. Note that the cellular thrombus appears to be surrounding a valve leaflet. *e*, Section through the swollen hind foot of a PAI-1 transgenic mouse. Note that the vein (V) appears to be completely occluded, whereas the artery (A) appears normal.

METHODS. The transgene construct for PAI-1 was assembled as a four-part ligation. A *Bam*HI fragment (1,397 base pairs (bp)) was isolated from a PAI-1 plasmid containing the complete coding region, 80 bases of the 5′ untranslated region, and 140 bases of the 3′ untranslated sequence (obtained from human umbilical vein endothelial cells). The PAI fragment was ligated on the 5′ end to a 1,800-bp *Eco*RI–*Bgl*II metallothionein promoter fragment derived from pdBPV-MMT neo (342-12) (obtained from P. Howley, NIH) and on the 3′ end to a 220-bp *Bam*HI–*Sph*I fragment from the polyadenylation signal sequence of bGH (obtained from F. Rottman, Case Western). The vector was pBS (Bluescribe; Stratagene) prepared as an *Eco*RI–*Sph*I fragment. The metallothionein promoter and the bGH polyadenylation signal DNA were phosphatased and ligated to the PAI DNA overnight 12 °C at a 2:1 molar ratio. In collaboration with DNX (Athens, Ohio) eggs from B6/SJL-F_1J mice were microinjected with the ~3,400-bp *Eco*RI–*Sph*I DNA fragment and implanted in foster mothers according to established protocols. Mice were photographed with a Nikkormat camera using a medical lens and Kodak 100 ASA, daylight-balanced film. For histological evaluation, 30 G_1 and G_2 mice were killed at various ages by CO_2 inhalation. Tissues were fixed by immersion in 10% neutral-buffered formalin, processed, and embedded in paraffin according to established procedures. Tissue cross sections (5 μm) were cut, stained with haemotoxylin and eosin, and examined by light microscopy.

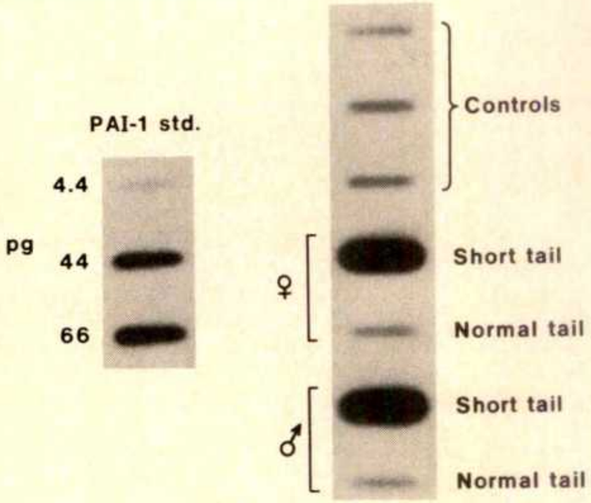

FIG. 2 PAI-1 DNA in tails of adult transgenic mice. Left, PAI DNA standard (std.); top right, tail DNA obained from control mice; bottom right, tail DNA from female and male short-tailed and normal-tailed mice.

METHODS. DNA was prepared from tails by dicing them with a razor blade into 700 μl of SSTE buffer (100 mM NaCl, 1% SDS, 50 mM Tris buffer and 15 mM EDTA, pH 8.0), then digestion with 0.5 $\mu g\ ml^{-1}$ proteinase K at 55 °C for 12 h. The mixture was then treated with 0.2 $\mu g\ \mu l^{-1}$ RNase at 37 °C for 1 h. An equal volume of phenol was added and the mixture was extracted twice. The aqueous phase was extracted with chloroform–isoamyl alcohol (24:1) and precipitated with isopropanol. The DNA was pelleted and washed with 70% ethanol and dried under vacuum. Buffer (100 μl TE) was added to each sample and the DNA quantitated spectrophotometrically. For slot blots, 10 μg purified DNA was fixed onto nitrocellulose and probed with a radiolabelled PAI-1 cDNA.

expression with the morphological and hisological profiles of the mice. Of the thirteen G_0 mice, six were selected for generation of the G_1 and G_2 lines used for subsequent analyses. Table 1(*a*) clearly indicates that tissue levels of PAI-1 protein also correlated directly with the presence of occlusions. Presumably, baseline PAI-1 detected in control and normal-tail animals reflects a low level of cross-reactivity between the anti-human PAI-1 monoclonal antibodies and endogenous murine PAI-1. Increased amounts of PAI-1 in the liver and kidney were expected on the basis of previous studies using the metallothionein promoter[11]; however, the raised level of PAI-1 protein detected in spleen tissue obtained from transgenic animals was surprising, and is as yet unexplained. The PAI-1 content of the cellular occlusions was not examined. These data show a strong link between the existence of venous occlusions and the presence and expression of the PAI-1 transgene. This relationship was examined more closely by determining the PAI-1 DNA copy-number and by measuring the PAI-1 mRNA and protein levels

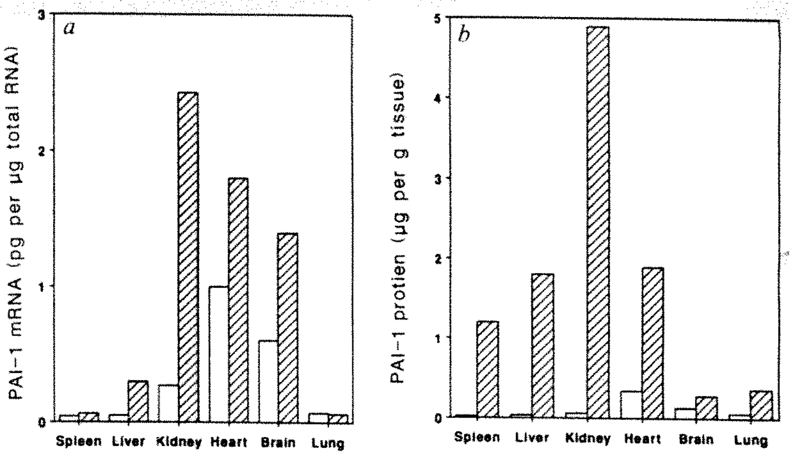

FIG. 3 Induction of PAI-1 expression in 28-day-old transgenic mice with ZnSO$_4$. *a*, PAI-1 mRNA in tissues of transgenic mice. *b*, PAI-1 protein in tissues of transgenic mice. Open bars, PBS control; hatched bars, ZnSO$_4$-injected. PBS or PBS containing ZnSO$_4$ was administered to 28-day-old mice IP (10 mg kg^{-1}). Eight hours after injection, mice were killed by cervical dislocation and tissues removed for RNA and protein analyses as described in Table 1.

in the livers of mice killed at different times after birth (Table 1(*b*)). As expected, DNA copy-number did not vary significantly within a phenotype. Both PAI-1 mRNA and protein declined, however, in the transgenic ('short tail') mice 4–28 days after birth to levels detected in control and normal-tail (non-expressing transgenic) mice. This decline paralleled the resolution of the venous occlusions in the hind limbs, and provides additional evidence of a strict correlation between the presence and expression of the PAI-1 transgene and the development of occlusions.

The decline of PAI-1 expression during the first 4 weeks after birth could result from the loss of responsiveness of the metallothionein promoter to endogenous control mechanisms. We addressed this issue by administering ZnSO$_4$ to 28-day-old transgenic mice that had shown tail necrosis and swollen hind limbs earlier in life. This treatment induced the expression of the PAI-1 gene from baseline levels to levels that in certain tissues exceeded those observed at day 4 (Fig. 3). Plasma PAI-1 was increased by ~20-fold after ZnSO$_4$ treatment (data not shown). We conclude from these experiments that the metallothionein promoter was intact and responsive. Studies of the mouse[12] and the chick[13] have shown that expression of endogenous metallothionein peaks shortly before birth (mouse) or after birth (chick) and declines thereafter. Taken together, these data indicate that transgenic PAI-1 may decline after day 4 as a consequence of the normal function of mechanisms governing the expression of endogenous metallothionein.

We found that the level of PAI-1 protein directly reflects the amount of PA neutralizing activity detectable (data not shown). In addition, the occlusions in the PAI-1 transgenic mice are reminiscent of those present in protein C-deficient patients in that they are localized to the venous side of the circulation[14]. Thus, it is conceivable that neutralization of endogenous murine activated protein C may also contribute to the observed venous occlusive disorder. Distinguishing between these and other possibilities is made particularly difficult by the fact that the critical period of evaluation is before 4 days after birth. Indeed, it has not been possible to measure the endogenous circulating levels of these murine pro-fibrinolytic factors because of the small amounts of blood obtainable from mice of this age. Alternatively, the occlusions may result from a perturbation of the vascular endothelium that is associated with chronically elevated PAI-1. In this regard, PAI-1 binds to and is protected from inactivation by vitronectin, an important component of the extracellular matrix[15]. The cellular nature of the venous occlusions suggests that such a perturbation may have affected the cellular adhesive properties of the venous endothelium.

Regardless of the precise mechanism, however, the results presented here provide strong evidence that elevated PAI-1 is closely associated with the development of venous occlusions. This finding has important implications in the development of approaches to predict, treat, and possibly prevent thrombotic disorders by monitoring and regulating the endogenous fibrinolytic system. □

Massachusetts 02115, USA

KRÜPPEL (*Kr*), one of the zygotically active *Drosophila* segmentation genes, is expressed in a restricted domain during the blastoderm stage of embryogenesis and is involved in the control of development of the thoracic and abdominal segments of the fly[1]. *Kr* encodes a polypeptide containing DNA-binding zinc-finger motifs[2], disruptions of which yield *Kr* mutants[3,4]. We have assayed the transcriptional activities of wild-type Kr protein as well as Lac repressor/Kr fusion proteins in HeLa and CV-1 cells. Wild-type Kr and a Lac–Kr chimaeric protein repressed transcription from reporter promoters in which a consensus Kr binding site derived from sequences within the *even-skipped* promoter[5] had been inserted in an upstream position. We mapped the repression function of Kr to an alanine-rich amino-terminal region of the protein, as a Lac/Kr fusion protein containing only amino acids 26–110 of Kr repressed transcription from a reporter promoter containing

---

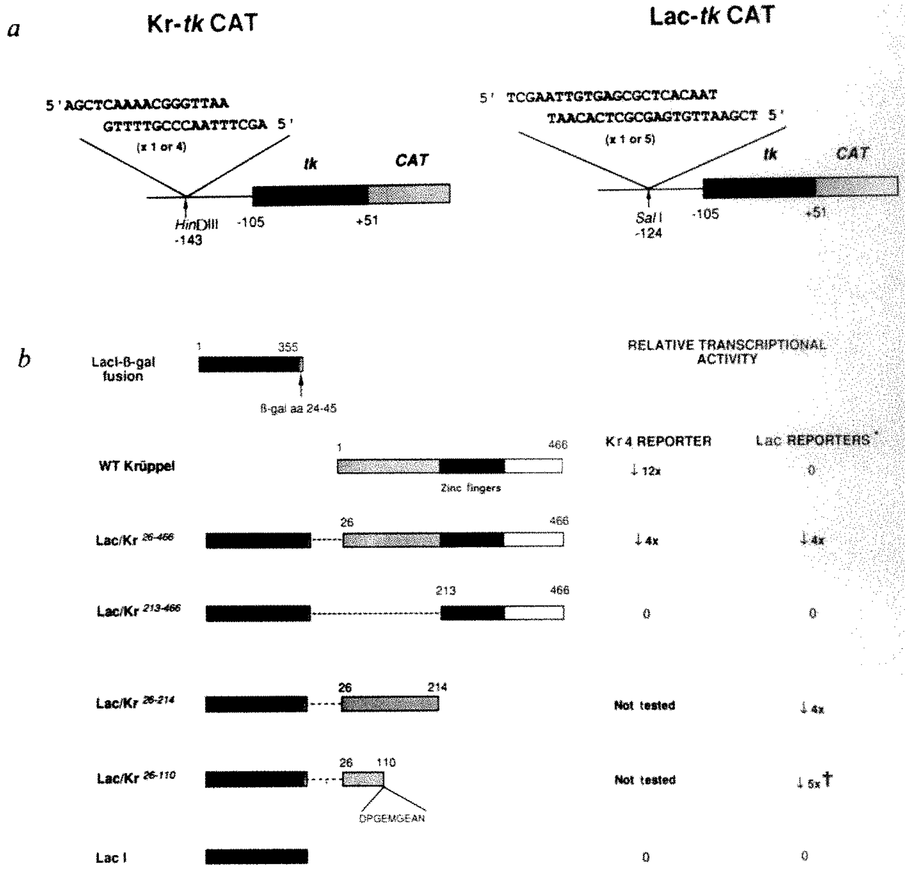

FIG. 1 *a*, Reporter constructs containing either synthetic duplex oligonucleotide Krüppel binding sites or *lac* operator sequences upstream of the HSV *tk* promoter. *b*, The structure of wild-type (WT) Kr and Lac-Kr chimaeric proteins. The table on the right of the figure indicates the relative transcriptional activities of Kr and Lac/Kr chimaeric proteins on the Lac-tkCAT and Kr4-tkCAT reporters as determined from 2-4 independent experiments. *Lac5-tkCAT was used in the demonstration of repression by Lac/Kr$^{26-110}$, whereas Lac1-tkCAT was the reporter gene in all other experiments. No significant difference in fold repression was noted when Lac/Kr$^{26-214}$ was co-expressed with Lac5-tkCAT versus Lac1-tkCAT. †Activities were assayed from transfection into HeLa cells, except for experiments with Lac/Kr$^{26-110}$, which were performed in CV-1 cells.

METHODS. Kr1-tkCAT and Kr4-tkCAT were constructed by the insertion of one or four duplex oligonucleotide Kr-binding sites[5], respectively, into the unique *Hin*dIII site of pBLCAT2 (ref. 21), which contains HSV *tk* sequences from −105 to +51. Lac1-tkCAT and Lac5-tkCAT were constructed by inserting one or five copies of a symmetrical *lac* operator sequence[22] with high affinity for lacI into the *Sal*I site of pBLCAT2. The pBLCAT2 plasmid also contains a wild-type *lac* operator located downstream of the *CAT* gene, within the pUC18 backbone, with an eightfold lower affinity for lacI. The lac repressor was expressed from plasmid pCMVlacI (ref. 22), containing the simian cytomegalovirus promoter. Wild-type *Kr* was expressed from a construct in which *lacI* sequences in pCMVlacI were replaced with the 2.3-kilobase (kb) *Eco*RI insert of pCK2B (ref. 2). The *Lac/Kr* fusion genes were constructed by linking a 1.4-kb *Bgl*II-*Pvu*I fragment encoding lac repressor amino acids 1-355 linked to 23 N-terminal amino acids (aa) of β-galactosidase[23] to portions of the *Kr* cDNA using synthetic duplex oligonucleotide adaptors to maintain the proper reading frame. The adaptors insert two additional amino acids (leucine and glutamic acid) between *lac* and *Kr* sequences. These fusions were cloned into Bluescript SK+ (Stratagene), excised by digestion with *Sac*I and *Eco*RI, then cloned into pCMVlacI digested with *Sac*I and *Eco*RI. The Lac/Kr$^{26-214}$ construct was made by restriction of Lac/Kr$^{26-466}$ at a unique *Bam*HI site at nucleotide 769 of the *Kr* cDNA, followed by end-repair with Klenow fragment and ligation to a linker containing stop codons in all three reading frames[24]. Lac/Kr$^{26-110}$ was constructed by *Bal*31 digestion of Lac/Kr$^{26-466}$, followed by ligation to HSV-*tk* polyadenylation sequences[25]. Nine amino acids (DPGEMGEAN; single-letter code) were added to the Kr amino-acid sequence by its fusion to the HSV-*tk* sequence through a *Bam*HI linker added to the *Sma*I site at nucleotide 1,417 of *tk*, preceding the termination codon. Constructs were confirmed by digestion of plasmids with restriction enzymes and by dideoxynucleotide sequencing of plasmids.

upstream *lac* operators. This demonstrates that the DNA-binding and repression activities of the Kr protein are distinct. These data are consistent with genetic evidence that Kr represses *even-skipped*[6,7] and *hunchback*[8] expression, and suggest that Kr is a negative regulator of transcription in *Drosophila*.

Mutations in *Kr* affect the expression of other gap genes[8,9] as well as pair-rule and homeotic genes[6,7,10,11]. The *Kr* gene product has been identified as a putative transcription factor by virtue of its zinc-finger motifs[2], nuclear location[12], and ability to bind specifically to DNA[5,9,13]. To test for transcriptional activity of the *Kr* gene product, the *Kr* complementary DNA was expressed in human and monkey cells from an expression plasmid containing the simian cytomegalovirus (CMV) promoter. This plasmid was co-transfected with the herpes simplex virus thymidine kinase (HSV-*tk*) promoter, containing one or four *Kr*-binding sites at nucleotide −143 (Kr1-tkCAT and Kr4-tkCAT, respectively) linked to a reporter gene (chloramphenicol acetyltransferase, CAT) (Fig. 1*a*). Expression of *Kr* protein led to a fourfold decrease in CAT activity from Kr1-tkCAT, and a 17-fold decrease in CAT activity from Kr4-tkCAT (Fig. 2*a*), compared with controls of the same reporter constructs co-transfected with a plasmid expressing the lac repressor from the CMV promoter. Cotransfection of the *Kr* cDNA with a reporter construct lacking Kr binding sites did not significantly affect CAT expression (Fig. 2*a*). To localize the region(s) in the Kr protein responsible for repressing transcription from the CAT reporter genes, fusions between sequences encoding portions of the Kr protein and of a heterologous DNA-binding protein, the lac repressor (lacI), were constructed (Fig. 1*b*). A fusion between lacI and amino-acid residues 26-466 of Kr (Lac/Kr$^{26-466}$) also repressed CAT expression from Kr4-tkCAT, whereas a fusion between lacI and residues 213-466 (Lac/Kr$^{213-466}$) of Kr did not (Fig. 2*b*). In addition, Lac/Kr$^{26-466}$ repressed CAT expression from a reporter construct containing an upstream *lac* operator at nucleotide −124 (Lac1-tkCAT), whereas a fusion lacking the N-terminal portion of Kr did not (Fig. 2*c*). The sequence encoding the N-terminal portion of Kr alone, deleting the zinc-finger domain required for DNA-binding activity (see below), was fused to *lacI* by insertion of a translation termination linker after residue 214 of Kr (Lac/Kr$^{26-214}$). Lac/Kr$^{26-214}$, like Lac/Kr$^{26-466}$, repressed transcription from Lac1-tkCAT (Fig. 2*c*). This demonstrates that the DNA-binding and repression functions of Kr are distinct. To further localize the region of Kr responsible for repression, Lac/Kr$^{26-214}$ and Lac/Kr$^{26-110}$ were each transfected along with a reporter construct containing five *lac* operators (Lac5-tkCAT) (Fig. 2*d*). The two fusion proteins repressed CAT expression to similar levels, indicating that an 85-amino acid region of Kr encodes the transcriptional repression activity. None of the Lac/Kr chimaeric constructs repressed CAT expression from a reporter devoid of Kr binding sites or high-affinity upstream *lac* operators (data not shown). Results from all transfections are summarized in Fig. 1*b*.

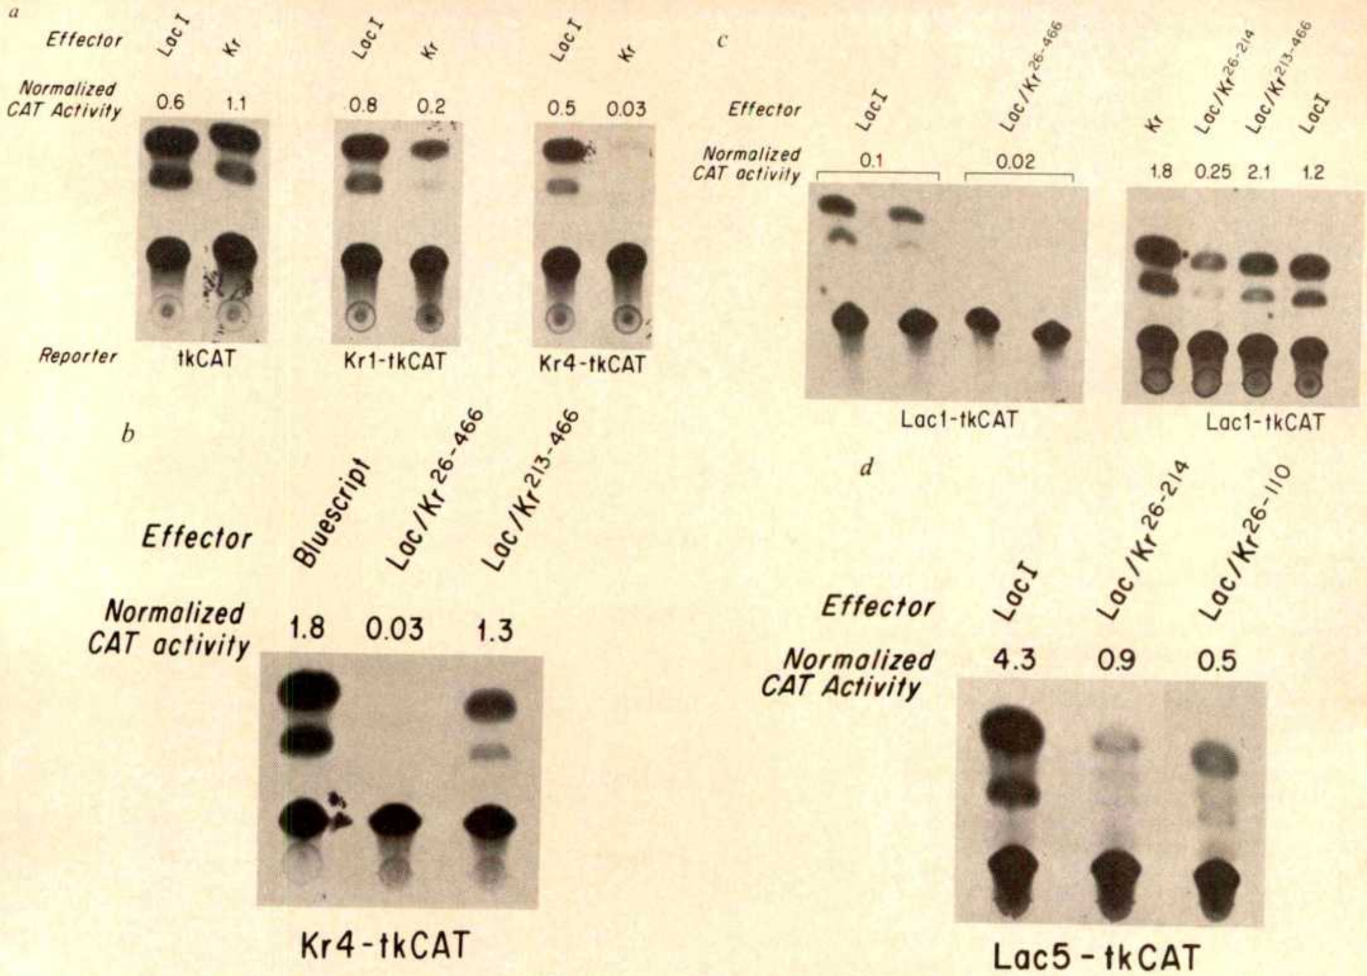

FIG. 2 Repression of CAT expression by Kr and lac repressor–Kr chimaeric proteins. *a*, Effect of wild-type *Kr* or *lacI* effectors on reporter constructs containing zero, one, or four Kr-binding sites upstream of the HSV-*tk* promoter in HeLa cells. *b*, Effect of Lac/Kr chimaeric proteins on the Kr4-tkCAT reporter in HeLa cells. *c*, Effect of Lac/Kr chimaeric proteins on the Lac1-tkCAT reporter in HeLa cells. *d*, Effect of Lac/Kr (N-terminal) chimaeric proteins on the Lac5-tkCAT reporter in CV-1 cells.

METHODS. HeLa cells, adapted to growth in DME medium supplemented with 10% calf serum, were plated at a density of 10^6 cells per 100-mm dish 24 h before transfection. Reporter constructs (5 μg), effector constructs (5 μg) and either 0.5 μg pXHGH5 or 2 μg pTKGH (ref. 26) as an internal control were co-transfected by the calcium phosphate-precipitation method[27]. CV-1 cells were grown in 10% newborn calf serum, plated at a density of 10^6 cells per 100 mm dish and transfected with 7.5 μg of both reporter and effector plasmid constructs, as well as 0.5 μg of pXHGH5. At 45 h post-transfection, cell-growth media were assayed for growth hormone levels[26] and cell extracts were prepared and assayed for CAT activity[27]. The percentage of acetylated chloramphenicol was divided by the growth hormone levels in the media (ng per ml) to normalize CAT activity for the efficiency of transfection. The experiment on the left of *c* was performed in duplicate with results averaged. In addition, the preparation of extracts and performance of CAT assays differed in the two experiments displayed in *c*, accounting for lower levels of CAT activity on the left portion of the figure.

FIG. 3 Comparison of the primary sequences of the *Drosophila* transcriptional repressors *Kr*, *engrailed* (*en*) and *even-skipped* (*eve*). *a*, Predicted amino-acid sequences from *Kr* (26–110) and *en* were optimally aligned by a computer algorithm that identifies maximally similar subsegments[28]. Identical matches are denoted by (*) and aligned residues that share similar physiochemical properties by (|). This region of Kr could be aligned to two segments of *D. melanogaster en* protein. Only the more C-terminal segment is common to Kr and the *en* protein of both *D. melanogaster* and *D. virilis*. *b*, Alignment found between Kr and *eve*, which overlaps the alignments with *en*. Secondary-structure predictions[29] indicate that these optimally aligned regions are all likely to contain α-helical structures.

The ability of the Lac/Kr fusion polypeptides to bind DNA specifically is necessary but not sufficient to affect repression. Extracts from cells transfected with the Lac/Kr fusion genes supported the formation of specific complexes with *lac* operator DNA (gel-mobility shift assays; data not shown), but only those constructs that contained N-terminal sequences of Kr (for example, Lac/Kr$^{26-214}$ and Lac/Kr$^{26-466}$) led to repression of transcription from reporter plasmids containing *lac* operators (Fig. 1*b*). Similarly, extracts from cells transfected with both Lac/Kr$^{26-466}$ and Lac/Kr$^{213-466}$ formed complexes with Kr-binding-site DNA (data not shown), but only the protein that contained N-terminal sequences led to transcriptional repression

(Fig. 1*b*). This emphasizes the separate nature of the DNA-binding and repression activities of Kr.

The ability of Kr to repress transcription of the reporter constructs described above is consistent with the role of Kr in limiting the boundaries of expression of the gap gene *hunchback* (*hb*)[8] and the pair-rule gene *even-skipped* (*eve*)[6,7] during the blastoderm stage of *Drosophila* development. Our data demonstrate that the Kr protein functions across species lines and contains a transcriptional repression activity, distinct from its DNA-binding activity, that can act at a distance from the start site of transcription. Repression is unlikely to result from steric hindrance, as the Kr and lacI binding sites were placed relatively far from the upstream activator-binding sites of the HSV-*tk* promoter and the start site of HSV-*tk* transcription[14]. Kr repression of the *eve* promoter might occur by competitive binding between Kr and the *hb* protein (Hb) to adjacent binding sites in the *eve* promoter, leading to the displacement of Hb, an activator of the *eve* promoter. Kr bound immediately adjacent to Hb might also mask or quench Hb activity by a protein–protein interaction[5]. Our data are more consistent with a direct model for repression at a distance[15], in which the N-terminal region of Kr would interact with more proximal components of the transcription machinery, such as upstream activator proteins (for example, CTF, TFIID), RNA polymerase II or its accessory proteins, thereby blocking the usual stimulation of transcription.

Comparison of the N-terminal region of Kr between amino acids 26 and 110 with the amino-acid sequence of two other *D. melanogaster* transcriptional repressors, *engrailed*[16,17] and *even-skipped*[17,18], reveals the existence of similar alanine-rich subsegments (Fig. 3). In addition, one region within the *engrailed* protein that is similar to Kr is evolutionarily conserved between *D. melanogaster* and *D. virilis*[19]. Although the functional significance of these alignments is not known, we are analysing deletions, point mutations and exchanges of sequences among these proteins to determine whether the aligned regions encode a common transcriptional repression activity. Such regions could mediate protein–protein interactions necessary to sequester components of the transcriptional machinery from interactions required to initiate transcription.

Genetic data indicate that Kr also acts as an activator of expression of the gap gene *knirps*, the promoter of which has been shown to contain Kr-binding sites[9]. This activation may depend on the context of the *knirps* promoter, and could be encoded by a different region of Kr. The *Ultrabithorax* (*Ubx*) protein both activates the *Ubx* promoter and represses the *Antennapedia* promoter; however, the activation function of the protein can be deleted without affecting repression activity[20]. We note that a C-terminal deletion of Kr after amino acid 377 yields a hypomorphic Kr phenotype[4], yet this region is not required for the repression function of Kr in our assay system.

Note added in proof: Deletion of the alanine-rich region of *eve* that can be aligned with *Kr* impairs the ability of *eve* to function as a transcriptional repressor in cultured *Drosophila* cells (K. Han and J. L. Manley, personal communication). ☐

Rapid evolution in response to high-temperature selection

Albert F. Bennett, Khoi M. Dao & Richard E. Lenski

Department of Ecology and Evolutionary Biology, University of California, Irvine, California 92717, USA

TEMPERATURE is an important environmental factor affecting all organisms[1,2], and there is ample evidence from comparative physiology that species[1,3] and even conspecific populations[4,5] can adapt genetically to different temperature regimes. But the effect of these adaptations on fitness and the rapidity of their evolution is unknown, as is the extent to which they depend on pre-existing genetic variation rather than new mutations. We have begun a study of the evolutionary adaptation of *Escherichia coli* to different temperature regimes, taking advantage of the large population sizes and short generation times in experiments on this bacterial species[6–10]. We report significant improvement in temperature-specific fitness of lines maintained at 42 °C for 200 generations (about one month). These changes in fitness are due to selection on *de novo* mutations and show that some biological systems can evolve rapidly in response to changes in environmental factors such as temperature.

A clone of a single cell in the ancestral line maintained at 37 °C for 2,000 generations was used to found six high-temperature (42 °C) and six control (37 °C) lines. All lines (ancestral, high-temperature and control) were propagated in Davis minimal medium[11] supplemented with 25 μg ml^{-1} glucose. Cultures (10 ml) were maintained by daily serial dilution into fresh medium, permitting a 100-fold increment in biomass ($\log_2 100 = 6.64$ generations of binary fission) each day. The total size of a population maintained under this culture regime cycles from $\sim 5\times10^6$ to $\sim 5\times10^8$ cells. The founding lines possessed one of two arabinose-utilization marker states[9,10], which were used for clonal identification in fitness assays and for monitoring possible cross-contamination between lines. Selective neutrality of these markers at both 37 °C and 42 °C was verified by preliminary experiments and no cross-contamination of lines was observed. Additional phenotypic markers were also used to exclude the possibility of contamination from external sources[9,10]. The use of an ancestral line that was already well-adapted to the culture medium increased the likelihood that temperature-specific adaptations could be detected, as opposed to other beneficial but non-temperature-specific mutations that might enhance adaptation to the culture medium. Also, by studying spontaneous mutants that have increased in frequency gradually by selection rather than mutants obtained by mutagenesis and subsequent screening for extreme phenotypes, one avoids mutations that have profoundly deleterious pleiotropic effects and consequently would have little evolutionary significance.

TABLE 1 Improvements in fitness during 400 generations at 42 °C

Generation	Estimated mean fitness over all lines*	Estimated variance in fitness among lines†
100	$\bar{X} = 0.991$ $t_s = -1.386$ $0.5 < P < 0.9$	$s_g^2 = 2.07 \times 10^{-6}$ $F_s = 1.008$ $0.25 < P < 0.5$
200	$\bar{X} = 1.085$ $t_s = 2.712$ $0.01 < P < 0.025$	$s_g^2 = 4.88 \times 10^{-3}$ $F_s = 6.122$ $P < 0.001$
400	$\bar{X} = 1.072$ $t_s = 2.827$ $0.01 < P < 0.025$	$s_g^2 = 2.92 \times 10^{-3}$ $F_s = 4.082$ $0.001 < P < 0.01$

* The mean and standard error of the mean were calculated from the means of the six fitness assays performed for each of the six lines. The corresponding t-statistic is shown, as is the significance level associated with the one-tailed hypothesis that the mean fitness across all lines relative to the ancestral clone was greater than one. The number of degrees of freedom employed in this test was five, corresponding to one less than the number of lines.

† Variance component due to differences in fitness among lines[14]. The corresponding F-statistic is shown, along with the significance level associated with the hypothesis that this variance was greater than zero. The corresponding degrees of freedom for the numerator and denominator in the F-ratio were 5 and 30, respectively.

After 100, 200 and 400 generations of binary fission (15, 30 and 60 days respectively), single colony isolates from each high-temperature line were made to compete against the ancestral clone possessing the alternative arabinose marker state. These competition experiments used the same culture conditions in which the high-temperature lines had been maintained. Six replicate competition experiments were run for each of the six lines at each sample time. Both competitors were preincubated at 42 °C for one day, such that each had equal opportunity to acclimatize physiologically to the culture conditions. Thereafter equal aliquots of each competitor were added to fresh medium; initial densities were determined by plating on medium that permitted the competitors to be distinguished on the basis of the arabinose-utilization marker state. The mixed culture was maintained at 42 °C for one day and the final densities of ancestral and high-temperature clones determined again by plating. These competition experiments enabled us to examine adaptive evolution (that is, improvement in fitness relative to the ancestral clone) by the high-temperature lines. Fitness (W) was defined as the ratio of the number of doublings for the high-temperature and ancestral clones: $W = \log_2 (N'_f/N'_i)/\log_2 (N_f/N_i)$ where N_i and N'_i are the initial densities and N_f and N'_f are the final densities of the ancestral and high-temperature clones, respectively[9,10]. A value of 1 indicates that two clones have equal fitness; a value greater than 1 indicates that the high-temperature line has adapted evolutionarily.

The major results are given in Table 1. At 100 generations of culture at 42 °C there was no significant increase in fitness nor significant heterogeneity in fitness among the six lines. At 200 generations, and again at 400 generations, fitness had increased significantly relative to the ancestral clone by an average of ~7–8%. Furthermore, analyses of variance indicated significant heterogeneity in fitness among the six lines at 200 generations and again at 400 generations. Thus, new mutations that increased fitness at 42 °C had occurred and reached high frequency within only 200 generations (30 days) in at least some of the high-temperature lines.

The control lines provide evidence that the adaptive evolution observed in the high-temperature lines was temperature-specific (Table 2). The six control lines maintained at 37 °C for 400 generations did not show any significant fitness improvement when competed at 37 °C against the same ancestral clone. Relative to their common ancestor, the fitness at 37 °C of the control lines was significantly less than the fitness at 42 °C of the high-temperature lines (one-tailed t-test; $t_s = 2.515$, 10 d.f., $0.01 < P < 0.025$).

We also determined whether the adaptive evolution observed in the high-temperature lines produced any correlated response in fitness at 37 °C, the ancestral temperature regime (Table 2). A significant fitness advantage was observed when the high-temperature lines were competed against the ancestor at 37 °C. Although the fitness advantage observed at 37 °C (~4%) was less than the advantage observed at 42 °C (~7%), this difference was not statistically significant (one-tailed t-test for paired comparisons, $t_s = 0.898$, 5 d.f., $0.1 < p < 0.25$). Also, mean fitnesses at 37 °C and 42 °C were not positively correlated across the high-temperature lines (coefficient of correlation $r = -0.088$, 4 d.f., $P > 0.5$). One possible explanation for this lack of correlation across lines is heterogeneity among alleles in their effects on a correlated character[9,12]. To examine this possibility we first computed the overall ratio of the correlated response to selection (mean change in fitness at 37 °C, Table 2) to the direct response to selection (mean change in fitness at 42 °C, Table 1): $(1.040 - 1)/(1.072 - 1) = 0.554$. This ratio provides an estimate of the regression of fitness at 37 °C on fitness at 42 °C (see equation 19.5a in ref. 13). We then used the jackknife procedure[14] to determine the influence of each fitness assay on this ratio. An analysis of variance using the jackknifed data (Table 3) indicates significant heterogeneity among the lines in this ratio, and hence in the relationship between fitnesses at 37 °C and 42 °C. Five of the six lines give a positive regression coefficient (mean slope from jackknifed data = 0.782) and among these five lines there is a significant positive correlation between mean fitnesses at 37 °C and 42 °C ($r = 0.968$, 3 d.f., $P < 0.01$). The other line gives a negative regression coefficient (mean slope from jackknifed data = −0.738) that obscures the overall correlation. There is evidently heterogeneity among alleles that improve fitness at 42 °C in their effect on fitness at 37 °C.

Even with such heterogeneity, the average correlated response of fitness at 37 °C for the high-temperature lines was significantly greater than the average direct response of the control lines at 37 °C (two-tailed t-test, $t_s = 2.982$, 10 d.f., $0.01 < P < 0.025$). This unexpected result demonstrates that adaptation to an environment may sometimes occur more rapidly as a consequence of selection in another environment than as a direct evolutionary response. We see three possible explanations for this phenomenon in our experimental system. First, certain mutations may occur only at higher temperatures. Second, the high-temperature regime may have increased the rate of certain mutations[6,15], including some beneficial mutations sufficiently rare that they were not yet observed at 37 °C. Third, equivalent mutations may have occurred at the same rate at 37 °C, but were not fixed during this period because of a smaller selective

TABLE 2 Temperature-specificity of improvements in fitness

Estimated mean fitness over all lines*	Estimated variance in fitness among lines†
Direct response of fitness at 37 °C after propagation at 37 °C for 400 generations	
$\bar{X} = 1.006$ $t_s = 1.164$ $0.1 < P < 0.25$	$s_g^2 = -1.28 \times 10^{-4}$ $F_s = 0.587$ $0.5 < P < 0.75$
Correlated response of fitness at 37 °C after propagation at 42 °C for 400 generations	
$\bar{X} = 1.040$ $t_s = 4.056$ $0.001 < P < 0.01$	$s_g^2 = 2.13 \times 10^{-4}$ $F_s = 1.585$ $0.1 < P < 0.25$

* See Table 1.

† See Table 1.

TABLE 3 Heterogeneity in ratio of correlated response (change in fitness at 37 °C) to direct response (change in fitness at 42 °C) among lines propagated at 42 °C for 400 generations*

Source	Degrees of freedom	Sums of squares	Mean square	F_s
Among lines	5	24.24	4.85	2.76
Within lines	66	115.91	1.76	$0.025 < P < 0.05$
Total	71	140.14		

* The overall ratio of the correlated response (Table 2) to the direct response (Table 1) is calculated in the text. The jackknife procedure[14] was used to compute pseudovalues that indicate the influence of each of the 72 fitness assays (six assays at each of two temperatures for each of six lines) on this overall ratio. The grand mean of the pseudovalues was 0.529, close to the overall ratio. The analysis of variance tests for heterogeneity among lines in pseudovalues. Significant heterogeneity indicates genetic variation among lines in the effects of alleles that improve fitness at 42 °C on fitness at 37 °C. See text for details.

advantage at this temperature (smaller selective advantage both increases the probability that a favourable mutation will be lost initially owing to genetic drift and increases the amount of time that would be required for the favoured mutant allele, if it is not lost by drift, to reach some specified high frequency[16,17]). These results also bear on the issue of whether there necessarily exists a negative genetic correlation (that is, pleiotropic trade-off) between fitnesses measured in different environments (for example, temperatures[18]). The correlated improvement in fitness at 37 °C in most of the high-temperature lines clearly indicates no necessary loss of fitness in the ancestral environment (37 °C) during adaptation to a new environment (42 °C).

Selection studies, in which one monitors the response of laboratory populations to variation in natural environmental variables, may provide a powerful tool to investigate and predict the response of natural populations to environmental variation[19] (for example, climate change[20,21]). Our experiments demonstrate that some bacteria can respond to changes in temperature in ways that improve evolutionary fitness over short absolute time periods. Mutations favouring such fitness improvement are evidently not rare and can spread rapidly through a population. Some organisms may therefore be able to track and evolve in response to temperature changes in their environments even seasonally and certainly over longer time periods. ☐

Proximity to the promoter inhibits recognition of cauliflower mosaic virus polyadenylation signal

Hélène Sanfaçon & Thomas Hohn

Friedrich Miescher Institut, PO Box 2543, CH-4002, Basel, Switzerland

THE replication of retroviruses and pararetroviruses (such as caulimo- and hepadnaviruses)[1] involves the production of terminally redundant genomic-length RNA (Fig. 1). The sequence repeated at both ends of the RNA (the R region) contains a polyadenylation signal, and for production of full-length RNA the version of this at the 5′ end of the template must be bypassed by RNA polymerase, but the version at the 3′ end must be recognized[2–5]. This implies that the position of the polyadenylation signal determines its efficiency, and we report here experiments aimed at investigating the basis of this phenomenon. Our results with cauliflower mosaic virus[6] suggest that proximity to the transcription initiation site inhibits messenger RNA 3′-end processing directed by polyadenylation signals.

To test whether the cauliflower mosaic virus (CaMV) R region without additional upstream CaMV sequences was sufficient to direct 3′-end processing in plants, we inserted the chloramphenicol acetyltransferase (CAT) reporter gene at the beginning of the R region (plasmid R-CAT, Fig. 2*a*). A DNA fragment from the nopaline synthetase gene (*nos*), containing a second polyadenylation signal[7,8], was placed downstream of R to rescue RNA molecules that were not processed at the CaMV site. Total RNA was purified from transiently transfected plant protoplasts (*Nicotiana plumbaginifolia*) and analysed in RNase protection assays using an antisense probe (P1) that covered both polyadenylation signals (Fig. 2*a*, *b*). Only one major band was obtained, which was of the expected size (190 nucleotides) for a transcript processed at the CaMV site. Processing at this site

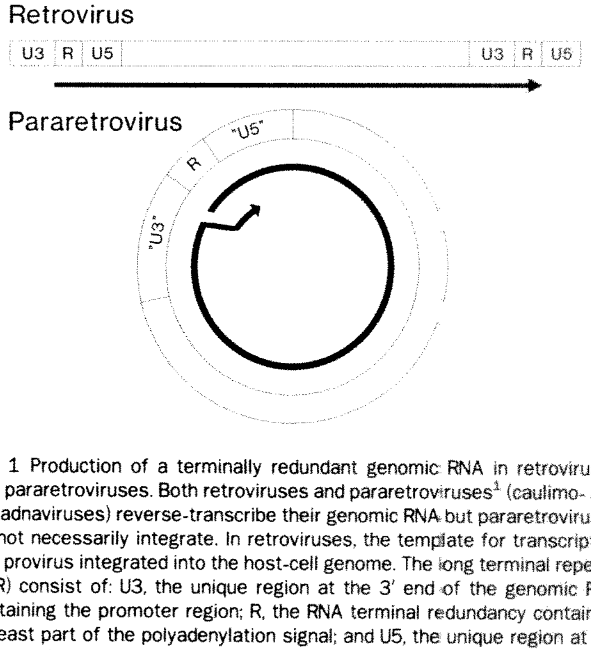

FIG. 1 Production of a terminally redundant genomic RNA in retroviruses and pararetroviruses. Both retroviruses and pararetroviruses[1] (caulimo- and hepadnaviruses) reverse-transcribe their genomic RNA but pararetroviruses do not necessarily integrate. In retroviruses, the template for transcription is a provirus integrated into the host-cell genome. The long terminal repeats (LTR) consist of: U3, the unique region at the 3′ end of the genomic RNA containing the promoter region; R, the RNA terminal redundancy containing at least part of the polyadenylation signal; and U5, the unique region at the 5′ end of the RNA. In cauliflower mosaic virus (CaMV), the template for transcription is a circular mini-chromosome. The genomic 35S RNA and the subgenomic 19S RNA use the same poly(A) addition site[10]. Regions equivalent to the retrovirus U3 and U5 are defined by the start site of (−) and (+) strand DNA synthesis during reverse transcription. In CaMV, 'U3' contains the 35S promoter from which the genomic RNA is transcribed and R contains all the elements necessary for 3′-end processing of the 35S and the 19S RNA.

was abolished on deletion of the consensus hexanucleotide AATAAA (ref. 9) in R (construct R-CATΔ, Fig. 2*b*). A new band of 280 nucleotides was then obtained, the expected size for transcripts reading through R and being processed 20 nucleotides downstream of a cryptic AATAAA in the *nos* signal[7,8]. This AATAAA is located 120 nucleotides upstream of the natural *nos* gene poly(A) addition site. Additional elements within the CaMV R are likely to be responsible for the recognition of this cryptic site in our experiments.

To measure the bypass of the CaMV polyadenylation site at the 5′ end of the genomic RNA, we modified plasmid R-CAT by placing R immediately downstream of the 35S RNA promoter (the CaMV equivalent of U3, Fig. 1). On RNA mapping with probe P1, we detected three bands of the expected size for transcripts processed at the CaMV poly(A) addition site and at the normal and the cryptic sites in the *nos* segment (plasmid R0, Fig. 2*c*, *d*). The proportion of transcripts processed at the CaMV versus the *nos* sites was used as a measure for the bypass of the first signal (Fig. 2*e*). About two-thirds of the transcripts were processed at the end of R and one-third at the two *nos* sites.

To determine whether the inefficient use of the CaMV poly(A) addition site in construct R0 was caused by its proximity to the RNA 5′ end, a 40 nucleotide polylinker was placed at the beginning of R (construct R1). DNA fragments of increasing length, isolated from calf thymus DNA, were inserted into the polylinker creating constructs R2–R7 (Fig. 2*c*). Increasing the

	R0	R1	R2	R3	R4	R5	R6	R7

cryptic nos	10	8	6	3	3	3	2	<2
nos	25	19	12	1	<1	<1	<1	<1

FIG. 2 Changes in recognition of the CaMV polyadenylation signal on increasing RNA length. *a*, *c*, RNA mapping strategy. The 35S promoter, CAT reporter gene, CaMV R plus 20 nucleotides of CaMV downstream sequences (empty box), and *nos* polyadenylation signal (nos!) are shown. All plasmids except R0 contain a 40-nucleotide polylinker (thick black line) between the third and fourth nucleotide of R, used for insertions. In construct R-CATΔ, the AATAAA deletion is indicated (Δ). Normally used (small black arrows) and cryptic (small open arrow) 3′-end cleavage sites in R and *nos* fragments, transcripts (thin lines and arrows) and 300-nucleotide antisense probes P1 and P1Δ containing part of the polylinker (upper thick line) are shown. Sizes of expected protected fragments are given. *b*, *d*, RNase protection assays. Lane M_r, relative molecular mass markers as ^{32}P-labelled single-stranded DNA fragments. Hybrids are shown before (−) and after (+) digestion. Lane 'mock', transfection in absence of input plasmids. *d*, A patchwork of several exposures of the same gel was assembled to compensate for variation in total RNA recovered. This is measured by comparing the intensity of the band (I.C.) corresponding to a cotransfected internal control plasmid containing a truncated R (without *nos* fragment), partly homologous to probe P1 (120 nucleotides). Lane I.C., transfection with internal control only. *e*, Quantitation of transcripts produced. Percentage of processing: the ratio of the relevant band was determined by optical densitometry (the number of labelled nucleotides in each band was taken into account). Average numbers from this and three other independent experiments are given.

METHODS. DNA constructs: R-CAT, *Eco*RI (35S promoter and CAT gene) and *Eco*RI-*Hin*dIII (R) fragments of pDW2[18] and *Sac*I-*Eco*RI (nosPA) fragment of pBI 101 (ref. 19) into pIC19R$^+$ (ref. 20) polylinker; R-CATΔ, deletion of AATAAA within R by oligonucleotide-directed mutagenesis; probes P1 and P1Δ, *Pst*I-*Eco*RI (R) and *Eco*RI (nosPA) fragments of R-CAT and R-CATΔ into pGEM2 (Promega) polylinker; R0, *Nco*I-*Sca*I fragment (6,909–7,632) of CaMV-S[21] into *Nco*I-*Kpn*I(blunted) fragment of R-CAT; R1, *Eco*RI (35S promoter and R) fragment of pDH51[18] ligated to *Eco*RI fragment of R0, R2–R8, random calf thymus *Sau*3A DNA fragments into *Bam*HI site of R1 polylinker. Protoplast transfection and RNA analysis: *N. plumbaginifolia* protoplasts were transfected and total RNA purified after 6 h and mapped by RNase protection as described[22,23]. DNase treatment was included.

space between the transcription initiation and the CaMV poly(A) addition site resulted in an increased proportion of transcripts processed at the CaMV site (Fig. 2*d* and *e*). A pre-mRNA length of over 600 nucleotides resulted in <2% read-through of the CaMV signal. Sequencing of the inserts revealed no obvious homology to known consensus sequences beneficial for 3′-end processing. It is interesting that increasing the distance between the 35S promoter and the polyadenylation sites also resulted in progressively stronger recognition of the cryptic over the normal *nos* site (Fig. 2*e*). The data shown were obtained with *N. plumbaginifolia* (Solanaceae) protoplasts, which is not a host for CaMV infection. Similar results were obtained with *Orychophragmus violaceus* (Crucifereae) protoplasts, a CaMV host (data not shown).

If these results were to apply to natural CaMV infection of plants, then roughly two-thirds of the initiation events would be aborted by processing and polyadenylation at the 5′ R element, leading to the production of a large amount of 'short stop' RNA. To test this, total RNA was purified from an infected turnip plant and mapped with a probe covering R and 3′ and 5′ flanking sequences (Fig. 3*a*). We expected protected fragments of 180 nucleotides for the short-stop transcript, 220 nucleotides for the 5′ end of the 35S genomic RNA, and 260 nucleotides for the 3′ ends of the 19S and 35S RNAs[10] (Fig. 1). All three fragments were detected in both the total RNA and the poly(A)$^+$ fraction. The 220-nucleotide fragment was, however, also detected in the poly(A)$^-$ fraction, presumably as a result of degradation of the very long 35S RNA (8,200 nucleotides). As the short-stop RNA is present and polyadenylated in an infected plant, it will be interesting to investigate its possible role in CaMV infection.

To determine whether the spacing hypothesis for conditional recognition of a polyadenylation signal is relevant only for the CaMV system or reflects a more general feature of plant polyadenylation signals, the two signal-containing fragments were exchanged. The CaMV signal was then used to rescue the transcripts that bypassed the *nos* signal (Fig. 4*a*). Also, the efficiency of 3′-end processing at the *nos* site depended on its distance from the transcription start site (Fig. 4*b*). The three bands observed confirm the heterogeneity of the normal processing site described earlier[7]. Protected fragments corresponding to transcripts processed at the cryptic *nos* site were not detected in the lower part of the gel (data not shown).

Processing of the nascent RNA 3′ end probably occurs before termination of transcription[11-14]. On this basis, the progressive recognition of a polyadenylation signal with increasing pre-mRNA length could be explained by several mechanisms. One possibility is that the polyadenylation signal of a short transcript is poorly accessible to the processing/polyadenylation complex, perhaps as a result of steric hindrance caused by a capping enzyme bound to the 5′ terminus of the nascent RNA[15-16]; or similarly, the processing/polyadenylation complex might require a long foothold upstream of the poly(A) addition site. Alternatively, one could imagine that the RNA polymerase II initiation complex is converted *en route* to an elongation complex by progressive gain or loss of factors, allowing or preventing recognition of the polyadenylation signal. Denome and Cole[17] proposed that such a factor, either soluble or associated with the RNA polymerase, is involved in polyadenylation. Finally, a minimum mRNA length requirement could provide a simple explanation for the conditional recognition of some other retrovirus or retroelement polyadenylation signals. ☐

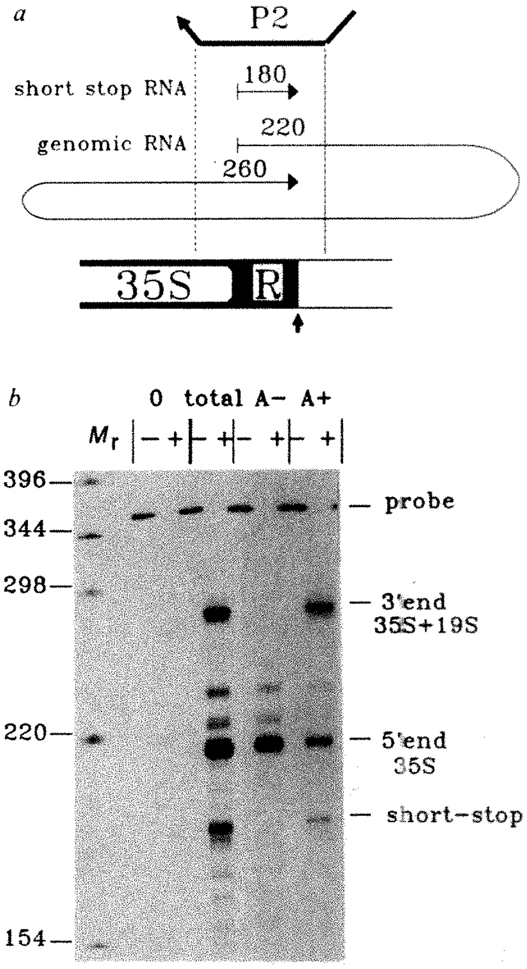

FIG. 3 Detection of the 'short-stop' transcript in an infected plant. *a*, RNA mapping strategy. Relevant CaMV regions (35S promoter and R), the anti-sense P2 probe and 35S genomic and short-stop RNAs with expected sizes of protected fragments are shown (as in Fig. 2). The 3′ end of 19S RNA (not shown) would also give rise to a 260-nucleotide protected fragment. *b*, RNase protection assay as in Fig. 2. Control lane 0, 10 μg transfer RNA was hybridized to probe P2; total, 1 μg total RNA; A$^-$, poly(A)$^-$ fraction from 1 μg total RNA; A$^+$, poly(A)$^+$ fraction from 1 μg total RNA.

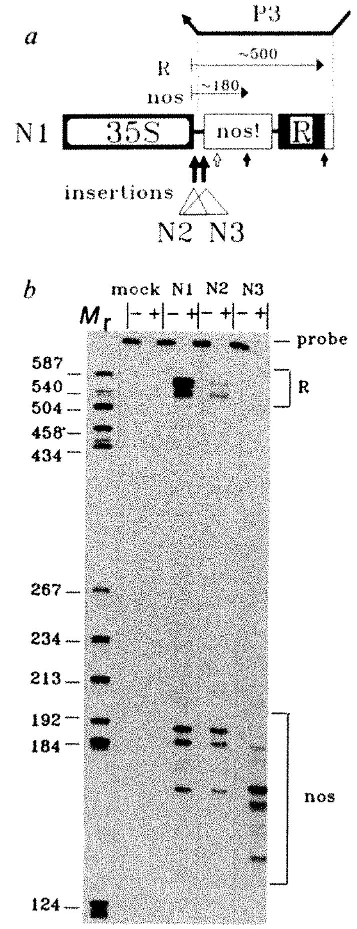
METHODS. DNA constructs: Ca100, a CaMV hybrid strain containing the *Bst*EII–*Bam*HI small fragment from CM4184[24] and the small *Bam*HI and large *Bam*HI–*Bst*EII fragments from CaMV-S[18] was used. Probe P2, *Eco*RV–*Bgl*II fragment of Ca100 (part of the 35S promoter, R and 40 nucleotides downstream) cloned into pGEM1 (Promega) polylinker. RNA analysis: total RNA was prepared 2 months after infection of the plant, essentially as described for protoplasts (Fig. 2). Poly(A)$^+$ and poly(A)$^-$ RNAs were fractionated by passage through an oligo(dT) cellulose column (Boehringer). RNA mapping was done as in Fig. 2.



c

	N1	N2	N3
nos RNA length (nucleotides)	200	420	1010
% processing: nos	60	80	>98
end of R	40	20	<2

FIG. 4 Changes in recognition of the *nos* polyadenylation signal on increasing RNA length. *a*, RNA mapping strategy. The elements in each construct are represented as in Fig. 2. Two restriction sites in the polylinker (large black arrows) were used for insertion of sequences to produce N2 and N3. Because the antisense probe P3 (upper thick line) covers most of the polylinker, slightly smaller protected fragments are expected for N3. Sizes of expected protected fragments are indicated above each transcript. *b*, RNase protection assay, as for Fig. 2. *c*, Quantitation of transcripts produced. The *nos* RNA length, distance between transcription start site and normal *nos* processing site. Percentage of *nos* read-through (average of two experiments) was calculated by comparing R transcript intensity with *nos* transcript intensity and accounting for the number of labelled nucleotides in each band.
METHODS. DNA constructs: N1, *Eco*RI-*Pst*I fragment of pDH51[18] (35S promoter), *Pst*I-*Hin*dIII fragment of pNOSCAT[25] (*nos* polyadenylation signal) and *Bam*HI-*Eco*RI fragment of pDH51 (R) cloned into pIC19R$^+$ polylinker[20]; N2, insertion of the calf thymus DNA used in R5 (Fig. 2) into *Bam*HI site of N1 polylinker; N3, exchange of the *Eco*RV-*Pst*I fragment for that of pDW2[18] (containing the CAT gene in *Sal*I site of N1 polylinker); probe P3, *Sma*I-*Eco*RI fragment of N1 into pGEM2 polylinker (Promega). Protoplast transfection and RNA analysis as in Fig. 2.

Identification of a 32K plasma membrane protein that binds to the myristylated amino-terminal sequence of p60$^{v\text{-}src}$

Marilyn D. Resh & Huai-ping Ling

Department of Biology, Lewis Thomas Laboratory, Princeton University, Princeton, New Jersey 08544, USA

THE transforming protein of Rous sarcoma virus, p60$^{v\text{-}src}$, is a myristylated membrane-bound phosphoprotein[1-3]. Interaction of p60$^{v\text{-}src}$ with the plasma membrane is essential for transforming activity[4-5], and is mediated by association with a membrane-bound Src receptor protein[6]. Evidence for the existence of an Src receptor is based on the ability of a myristylated peptide containing the N-terminal Src sequence to inhibit binding of p60$^{v\text{-}src}$ to plasma membranes *in vitro*: binding of p60$^{v\text{-}src}$ to a plasma membrane receptor is therefore mediated by N-terminal Src sequences[6]. Here we report that a myristyl-Src peptide, but not the corresponding non-myristylated peptide, can be specifically crosslinked to a plasma membrane protein of relative molecular mass 32,000 (M_r 32K). The 32K protein represents an Src-binding protein in the plasma membrane that is likely to be a component of the myristyl-Src receptor, and which could be involved in cellular transformation.

We have employed an N-terminal Src peptide to identify the Src receptor by chemical crosslinking according to the strategy outlined in Fig. 1. A myristylated Src peptide (MGYsrc) and the corresponding non-myristylated Src peptide (GYsrc) were synthesized[7], consisting of amino acids 2-12 of the mature Src polypeptide sequence with a C-terminal tyrosine residue appended. Both peptides were iodinated on tyrosine with chloramine T to a specific activity of 5×10^5 c.p.m. μg^{-1}. The ^{125}I-labelled peptides were incubated with plasma membranes from uninfected vole fibroblasts, the bifunctional crosslinking reagent BS^3 (Fig. 1) was added, and membranes were re-isolated by ultracentrifugation. When membrane-bound material was analysed by SDS-PAGE and autoradiography, a prominent iodinated band of M_r 33K was evident in membranes incubated with myristylated, but not with non-myristylated Src peptide (Fig. 2). Radiolabel incorporation into the 33K band was inhibited by non-radioactive MGYsrc peptide, but not by GYsrc peptide (Fig. 2). In addition, myristyl-peptides containing the N-terminal sequences of other known myristylated proteins (cyclic AMP-dependent protein kinase[8] and Gag polyprotein of murine leukaemia virus[9]) did not inhibit radiolabelling of the 33K band by iodinated MGYsrc (results not shown). The 33K band did

FIG. 1 Crosslinking strategy. The homobifunctional N-hydroxysuccinimide ester, bis(sulphosuccinimidyl) suberate (BS^3) was used to covalently crosslink iodinated myristyl-Src peptide (MGYsrc) to a membrane receptor by reaction with available amino groups. The MGYsrc peptide contains three potential sites for reactivity (epsilon amino groups of Lys, *).
METHODS. Myristyl (MGYsrc) and non-myristyl (GYsrc) peptides, synthesized as described[7] were iodinated on the C-terminal tyrosine residue with Na^{125}I and immobilized chloramine T (IODO-BEADS, Pierce), and were purified by chromatography through Sephadex G-10.

not represent an aggregate of crosslinked peptide alone, as no label was incorporated into a complex of this M_r in the absence of membranes (Fig. 2). Because the M_r of the MGYsrc peptide is ~1K, the M_r of the Src-binding protein detected in Fig. 2 is 32K.

Formation of a covalent complex between MGYsrc peptide and the 32K protein did not occur in the absence of a chemical crosslinker (Fig. 3*a*, lane 1), but was not limited to the use of BS^3 as a crosslinking agent. A 33K crosslinked product was also produced when a disulphide-containing derivative of BS^3, DTSSP, was employed (Fig. 3*a*, lane 5). As predicted, cleavage of the disulphide bond in DTSSP with free thiol resulted in dissociation of the complex between ^{125}I-labelled MGYsrc and the 32K protein (Fig. 3*a*, lane 4). Moreover, the heterobifunctional crosslinker MBS also resulted in attachment of ^{125}I-labelled MGYsrc to the 32K protein (Fig. 3*a*, lane 3). As MBS specifically crosslinks ligands containing primary amino groups to those containing sulphydryl groups, and the MGYsrc peptide contains no cysteine residues, the 32K membrane protein must contain a cysteine at or near the myristyl-peptide binding site. Finally, a similar 33K complex was formed between ^{125}I-labelled MGYsrc peptide and a 32K protein in membranes from vole fibroblasts transformed with Rous sarcoma virus (clone 1T) and from uninfected 3T3 fibroblasts, but not from membranes of *Escherichia coli* (Fig. 3*b*).

To better define the nature of the Src-binding protein, the 33K complex was analysed qualitatively and quantitatively. Formation of the 33K complex was sensitive to previous treatment of the membranes with trypsin (400 μg ml^{-1} for 30 min at 37 °C; 60% reduction of binding) or heat denaturation (3 min at 90 °C; 95% reduction), confirming that the 32K binding component is a protein. In uninfected vole cells, the distribution of the 33K complex paralleled that of 5′ nucleotidase, a plasma membrane marker enzyme[10] (Fig. 4*a*). This agrees with previous results showing MGYsrc peptide inhibits binding of p60$^{v\text{-}src}$ only in the plasma membrane fraction[6]. The amount of crosslinked MGYsrc peptide in the 33K complex was proportional to the amount of plasma membrane protein in the reaction (Fig. 4*b*). Moreover, addition of increasing amounts of ^{125}I-labelled MGYsrc to a constant amount of membrane protein demonstrated that formation of the 33K complex was saturable, with half-maximal binding occurring at ~6 μM peptide (Fig. 4*c*). These results indicate that binding occurs to a limited number of high-affinity sites, and is consistent with the interpretation that the 32K binding protein is a Src receptor. On the

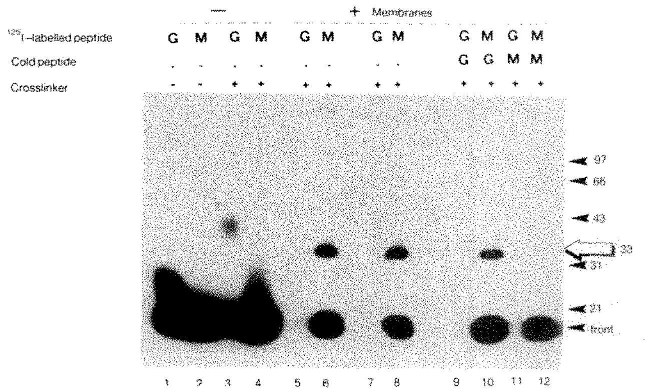

FIG. 2 Crosslinking of ^{125}I-labelled Src peptides to vole fibroblast plasma membranes. Odd-numbered lanes, ^{125}I-labelled GYsrc peptide. Even-numbered lanes, ^{125}I-labelled MGYsrc peptide. Lanes 1, 2, incubation in buffer; lanes 3, 4, incubation in buffer followed by 50 μg ml^{-1} BS^3 crosslinker. Reaction products from lanes 1–4 were run directly on the gel. Lanes 5, 6, incubation with membranes, followed by 50 μg ml^{-1} BS^3 crosslinker; lanes 7, 8, as lanes 5 and 6, respectively, except that the concentration of BS^3 crosslinker was 100 μg ml^{-1}, lanes 9, 10, as lanes 7 and 8, except that 250 μg ml^{-1} non-radioactive GYsrc peptide was added to the starting incubation mixture; lanes 11, 12, as lanes 7 and 8, except that 250 μg ml^{-1} non-radioactive MGYsrc peptide was added to the starting incubation mixture. Only membrane-bound material is depicted in lanes 5–12; no 33K band was evident in the supernatant. The positions of the M_r markers (in K), as well as the dye front and the 33K complex are indicated in the right margin. Free peptide runs at the dye front. Little GYsrc peptide binds to the membranes, and consequently is not evident at the dye front in samples where membranes were re-isolated. A small amount of GYsrc became crosslinked in the absence of membranes (lane 3). This complex did not bind to membranes and migrated with a slower mobility than the 33K MGYsrc complex.

METHODS. Each reaction contained 100 μl HNE buffer (10 mM HEPES (pH 7.4), 100 mM NaCl, 1 mM EDTA) or uninfected vole (*Microtus agrestis*) P100 plasma membranes in HNE (1 mg ml^{-1}), isolated as described[12]. Iodinated peptide (4×10^5 c.p.m. in 2 μl) was incubated with the membranes for 15 min at 20 °C, followed by 5 or 10 μl BS^3 crosslinker (1 mg ml^{-1} freshly prepared in dH$_2$O) for 15 min at 20 °C. Membranes were re-isolated by ultracentrifugation at 100,000 *g* for 15 min at 4 °C in a Beckman TL tabletop ultracentrifuge. The pellet was solubilized by sonication and boiling in SDS-PAGE sample buffer[13], and released material analysed on a 10% acrylamide gel and autoradiography. Exposure was for 14 h at −80 °C with intensifying screen.

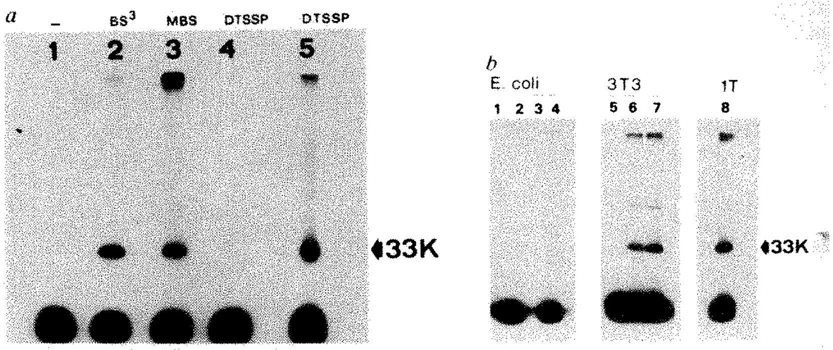

FIG. 3 The 33K complex can be formed with several different crosslinkers in plasma membranes from different species. *a*, Uninfected vole plasma membranes were incubated with ^{125}I-labelled MGYsrc, followed by incubation in the presence or absence of crosslinking reagent. Lane 1, no crosslinker; lane 2, 100 μg ml^{-1} BS^3; lane 3, 100 μg ml^{-1} *m*-maleimidobenzoyl-*N*-hydroxysulphosuccinimide ester (sulfo-MBS); lane 4, 100 μg ml^{-1} 3,3'-dithiobis (sulpho-succinimidyl-propionate) (DTSSP); lane 5, as lane 4 except no reducing agent (β-mercaptoethanol) was added to the electrophoresis sample buffer. Higher M_r oligomers (>300K), which did not enter the separating gel, were sometimes apparent (lanes 3 and 5). Exposure was for 21 h at −80 °C with intensifying screen. *b*, Lanes 1-4, *E. coli* membranes incubated with ^{125}I-labelled GYsrc (lanes 1 and 3) or ^{125}I-labelled MGYsrc (lanes 2 and 4) in the absence (lanes 1 and 2) or presence of 100 μg ml^{-1} BS^3. Lanes 5-7, 3T3 fibroblast plasma membranes incubated with ^{125}I-labelled MGYsrc in the absence (lane 5) or presence of 100 μg ml^{-1} BS^3 (lanes 6 and 7). Lane 8, plasma membranes from Rous sarcoma virus-transformed vole fibroblasts (clone 1T) incubated with ^{125}I-labelled MGYsrc and 100 μg ml^{-1} BS^3.

METHODS. Each reaction contained 100 μl membranes (30–40 μg) prepared from mammalian cells as a P100 fraction[12] or from *E. coli* as a total membrane fraction by osmotic shock[14]. Reaction conditions were as described (Fig. 2).

basis of the data in Fig. 4*c* and the specific activity of the iodinated peptide, we calculate that there are ~10×10^6 molecules of the 32K protein per cell, a number sufficient to accommodate the total number of p60$^{v\text{-}src}$ molecules estimated to be localized to the plasma membrane (1×10^6–2×10^6 per cell[11,12]).

One would predict that in cells transformed with Rous sarcoma virus, the number of available binding sites for ^{125}I-labelled MGYsrc would be lower than in normal cells, as many of the potential binding sites would be occupied by endogenous p60$^{v\text{-}src}$. To test this hypothesis, a titration experiment identical to Fig. 4*c* was performed on plasma membrane fractions from transformed vole cells (clone 1T). Formation of the 33K complex was saturable, and half-maximal binding occurred at 6 μM peptide. But the amount of 33K complex formed at saturation was 23% lower (±7%) than that detected in a parallel experiment with an identical concentration of nontransformed vole cell plasma membranes. Assuming the amount of plasma membrane protein is roughly the same in normal and transformed cells, and that the plasma membrane contains 10×10^6 molecules of the 32K protein, the presence of 2×10^6 molecules of p60$^{v\text{-}src}$ would be expected to reduce MGYsrc peptide binding by 20%, a value that agrees well with the results presented above. As the N-terminal 12 amino acids of the cellular protein p60$^{c\text{-}src}$ are identical to that of p60$^{v\text{-}src}$, the 32 K protein should also function as a receptor for p60$^{c\text{-}src}$. In uninfected cells, the calculated number of 32 K molecules is 100-fold greater than the number of p60$^{c\text{-}src}$ molecules, implying that the 32 K protein may function to bind other proteins in addition to p60$^{c\text{-}src}$.

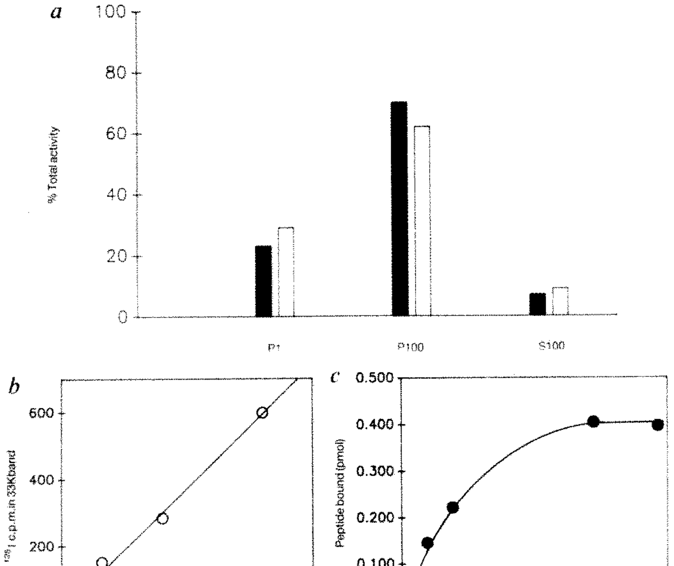

FIG. 4 Distribution and quantitation of the 33K complex. *a*, Crosslinking of ^{125}I-labelled MGYsrc to form the 33K complex (filled bars) and 5' nucleotidase activity (a marker for plasma membrane; open bars) were quantitated in nuclear (P1), plasma membrane-enriched (P100) and cytosolic (S100) fractions of uninfected vole fibroblasts. Each bar represents the average of duplicate experiments; standard deviations were ±5% or less. *b*, *c*, Formation of the 33K complex is dependent on the concentration of plasma membrane protein (*b*) and is saturable (*c*).

METHODS. *a*, Uninfected vole fibroblasts were fractionated in HEPES-containing buffers as described[12], and each fraction was resuspended in an equal volume of HNE. 5' nucleotidase activity was quantitated as described[10]. *b*, Each reaction contained the indicated amounts of uninfected vole fibroblast plasma membrane protein and 4×10^5 c.p.m. ^{125}I-labelled MGYsrc peptide. *c*, Each reaction contained 5 μg uninfected vole fibroblast plasma membrane protein and the indicated concentration of ^{125}I-labelled MGYsrc peptide. Reactions were performed as described (Fig. 2). The 33K band was excised from the dried gel and counted in a gamma counter.

Taken together, these data indicate that the 33K band represents crosslinking of the myristylated Src peptide to a component of the plasma membrane Src receptor. Both fatty-acid and amino-acid sequence moieties of p60$^{v\text{-}src}$ contribute to receptor recognition and binding. Receptor-mediated binding may therefore represent a general mechanism for localizing myristylated proteins to specific cellular compartments. We propose that the myristylated N-terminus of p60$^{v\text{-}src}$ is recognized by and binds to the Src receptor, and thus becomes anchored to the plasma membrane. Proof that the protein identified in this study mediates receptor function awaits isolation, purification and reconstitution of the 32K protein. ☐

Weak-affinity chromatography

D. Zopf and S. Ohlson

Weak-affinity chromatography is a new method using readily reversible biospecific recognition as the basis for chromatographic separations.

A NOVEL approach to affinity chromatography has emerged in recent years, taking advantage of weak (readily reversible) biospecific recognition as the basis for chromatographic separations[1]. Since its inception some 20 years ago, affinity chromatography has found application mainly as a small-scale, laboratory research operation[2]. The standard scheme is basically an on/off procedure, using high-affinity (association constant, $K_{ass} > 10^5$ M^{-1}) biomolecular recognition between the substance to be purified (the ligate) and the corresponding immobilized interactor (the ligand). The procedure has never gained wide acceptance either as a general analytical tool or in large-scale industrial operations, primarily because of high cost, low throughput, poor recovery of bioactivity, and lack of resolving power.

The stage has been set for a revolution in affinity chromatography by the simultaneous development of macroporous silica/polymer supports for HPLC[3], highly efficient chemistries for coupling ligands, and ready access to multi-milligram amounts of proteins or peptide fragments produced by cellular or molecular cloning techniques. Instead of a process whereby substances are extracted from the mobile phase by virtue of high-affinity interactions with an immobilized ligand, the new approach uses weakly interactive systems where, typically, $K_{ass} = 10^2$–10^4 M^{-1}. Porous matrices comprised of small particles (D_p = 5–10 μm) provide large available surface areas for ligand coupling, permitting ligand loads of, for example, proteins, up to 100 mg ml^{-1} column bed, while maintaining relatively short diffusion distances between active ligands. When purified and concentrated in an immobilized form, weak-affinity ligands can effect rapid and highly specific separation of ligates as retarded peaks under near physiological conditions, readily adaptable to quantitative measurement and experimental control.

Chromatographic perspectives

Weak-affinity chromatography based on biospecific recognition differs from other forms of interactive chromatography such as ion exchange and reversed phase only in the nature of the interaction between analyte and matrix, and is best understood in terms of basic chromatographic theory[4]. The capacity factor (k') that determines retention of a particular ligate is directly related to the amount of active immobilized ligand (L) as well as to the affinity between the ligand and ligate, according to the following equation:

$$k' = C[\mathrm{L}]K_{ass} \quad (1)$$

where C is a constant (with a value usually in the range 0.5–1.0) that reflects column features such as void fraction, porosity and density. Equation 1 is operative as long as the concentration of ligate at injection (c_o) is such that the product $K_{ass}c_o << 1$, that is, the Langmuir adsorption isotherm for the system is within the linear range. It is worth noting that as affinity decreases, retention also decreases, but, at the same time, higher concentrations of injected ligate can be accommodated without loss of performance due to sample overload. Thus, in principle, weak-affinity chromatography favours rapid throughput and process scale-up. From equation 1, it is clear that significant retention (k' = 1–10) in a weak-affinity system depends upon a high concentration of active ligand coupled to the solid phase. For example, to achieve $k' = 1$ with an immobilized IgG monoclonal antibody (M_r = 160 kD) at $K_{ass} = 10^3$ M^{-1} and $C = 1$, the required concentration of antibody on the column bed is approximately 75 mg ml^{-1}.

Weak-affinity separations

An example of chromatography on a 2-ml column loaded with 86 mg of monoclonal IgG coupled to tresyl-activated 10 μm porous silica particles is shown in Fig 1. Results from this and similar experiments confirm theoretical predictions that weak-affinity separations can have good chromatographic efficiency (narrow peaks and high plate numbers). Use of the weak-affinity approach overcomes the poor performance of traditional affinity chromatography, which is mainly due to slow desorption (desorption rate constant: $k_d << 1$ s^{-1}). The chromatographic performance of weak-affinity chromatography actually improves as the strength of ligand/ligate interactions diminishes, in sharp contrast to traditional immunoassays and ligand-receptor binding assays, which are designed to perform with maximal efficiency for measurement of high-affinity ($K_{ass} > 10^6$ M^{-1}) recognition events.

A striking prediction from theory is that weak-affinity chromatography has the potential to resolve completely several similar molecular species present in a crude extract. Figure 2 shows computer-generated elution profiles for small molecular weight ligates with differing weak affinities ($K_{ass} = 10^2$–5×10^3 M^{-1}) for monoclonal IgG immobilized on an HPLC column. For this simulation, a suitable separation 'window' is defined over a range of capacity factors k' = 1–12. The

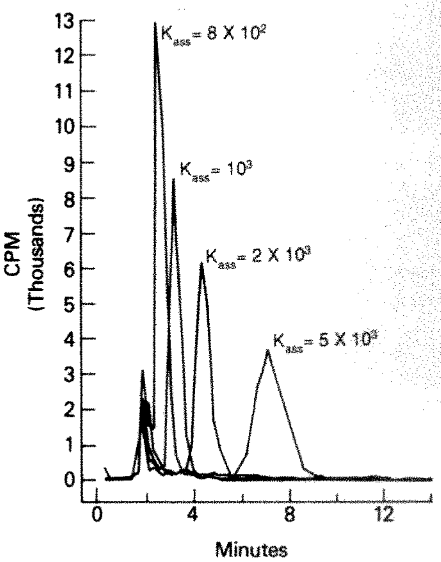

FIG. 1 Weak-affinity chromatography of the tritiated alditol of a glucose-containing tetrasaccharide, $(Glc)_4$, on a 2-ml tresyl-activated SelectiSpher 10 macroporous silica HPLC column coated with IgG[1].

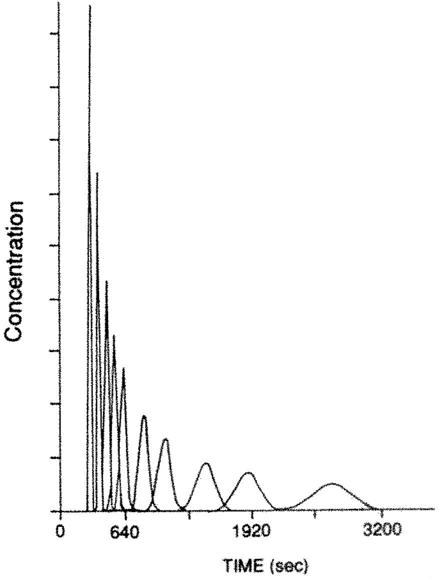

FIG. 2 Computer-generated chromatogram of weak-affinity chromatography of small ligates (M_r = 600 D) on an HPLC column coated with immobilized monoclonal IgG antibody. K_{ass}, varied between 10^2 and 5×10^3 M^{-1}.

first and second peaks represent non-retarded and very weakly interacting species ($K_{ass} < 5 \times 10^2\ M^{-1}$) which, in practice, elute as a single 'void-volume' peak. The subsequent eight peaks illustrate the theoretical potential for weakly bound, 'cross-reacting' ligates to be separated isocratically by more than 90 per cent in less than one hour by HPLC. Figure 3 shows isocratic separation of the α- and β-*p*-nitrophenyl glycosides of maltose dissolved in a crude extract of fetal bovine serum using an HPLC column loaded with a monoclonal IgG antibody that binds the ligates with $K_{ass} = 10^3$–$10^4\ M^{-1}$.

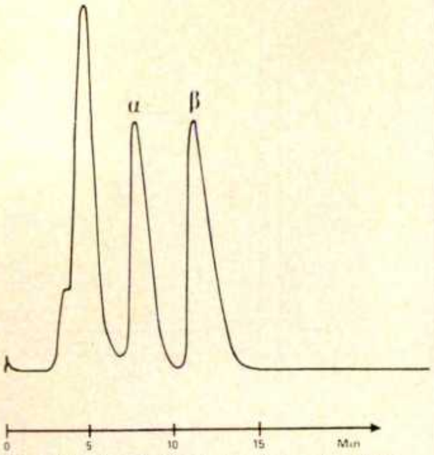

FIG. 3 Weak-affinity chromatography of the α- and β-*p*-nitrophenyl glycosides of maltose. 20 μl of sample containing 0.1 μg of each glycoside dissolved in a crude extract of 4 % fetal bovine serum was injected onto a 10 cm × 5 mm SelectiSpher 10 HPLC column coated with immobilized IgG monoclonal antibody. The column was eluted at 1 ml min^{-1} with 0.02 M sodium phosphate, 0.2 M sodium chloride, pH 7.5 at 45 °C and the eluate monitored for absorption of light at 300 nm.

Is weak binding specific?

The general observation that non-specific adsorption of solutes to chromatography support media is often of weak affinity does not support the converse statement that weak-affinity interactions are, by nature, non-specific. The specificity experienced in weak-affinity chromatography is the cumulative result of many serial weak-binding events whose kinetics, although readily reversible, depend upon binding energies between ligand and ligate that are significantly greater than the random weak interactions between biomolecules. The practical consequences of this specificity are evident in analyses for a specific oligosaccharide performed on crude samples such as human urine or serum[5], where the analyte in such analyses appears as a single retarded peak, well-separated from hundreds of other compounds present at similar or much higher concentrations.

Future trends

As a research tool, weak-affinity chromatography is ideally suited to identification, isolation and systematic investigation of the components of weak bioaffinity reactions. For example, it may offer a means to define the targets recognized by 'lectin-like domains' of cell-surface glycoproteins isolated from membranes of interacting cells.

As a diagnostic tool, weak-affinity chromatography can measure multiple related, or (by combining appropriate ligands) multiple unrelated molecules in complex mixtures within a few minutes. In this respect, it promises to extend the application of immunoassays to families of highly similar molecules that are difficult to discriminate by traditional methods.

As a preparative tool, weak-affinity chromatography enables purification under mild buffer conditions, preserving the bioactivity of molecules. The potential of the weak-affinity method will be more fully realized when macroporous supports are coated with active fragments of macromolecules, such as variable-region, heavy-chain fragments representing weak-affinity monoclonal antibodies. This approach will permit significantly higher active ligand loads, improve preparative capacity and extend the usable affinity range. ☐

What's new in chromatography

A column designed to eliminate the problem of charge interaction and a preparative/analytical high-performance centrifugal partition chromatography system — highlights of this week's chromatography/HPLC feature.

FOR sample injection and complex liquid handling tasks, E. Merck recommends its LiChroGraph (AS-4000) **autosampler for HPLC** (*Reader Service No. 101*). Offering a 150 standard-vial capacity or 200 micro vials, the LiChroGraph provides three types of sample application: complete or partial filling of the loop, as well as micro-application for virtually zero sample loss, says E. Merck. The autosampler can also be used to perform sample dilution steps before analysis, pipetting and mixing during pre-column derivatization. The addition of internal standards and the take-up and injection of a second phase in two-phase systems are additional features. All instrument functions, from simple needle movements to complex valve switching, are fully programmable. Run programs can be stored in the autosampler's memory. Full PC control of the instrument via a RS232C interface allows the storage of large numbers of application-orientated programs in the PC's memory.

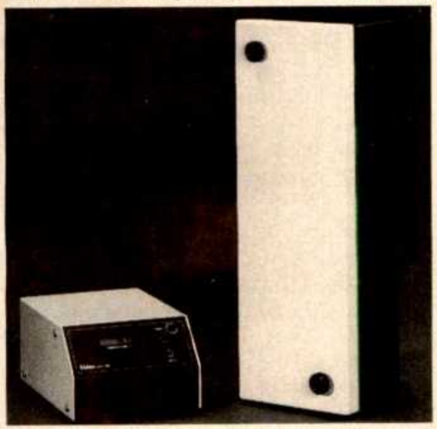
Merck's autosampler with 150-vial capacity.

Severn Analytical's SA 6160 **programmable autosampler** for HPLC has a 160-sample capacity and provides round-the-clock unattended analyses (*Reader Service No. 102*). The autosampler's injection mechanism is designed in such a way as to make the injection needle an integral part of the sample loop; this set-up eliminates carryover and ensures that the sample needle is continually flushed out with mobile phase. Injection volumes from 0.1 to 250 μL can be selected individually for each vial, with a reproducibilty of better than 0.3 per cent standard deviation, says Severn. Using a hand-held control panel, users can program the SA 6160 with run parameters for run time, injection volume, number of injections and timed events. Parameters can also be changed during the run. Practical options include a thermostatted column compartment, column switching valves and a pre-column derivatization facility for amino acid analysis.

Accessories or necessities?

Plasti-Flex **chromatography columns** from Kontes with polycarbonate plastic barrels are designed to eliminate the problem of charge interaction between glass and some biomolecules (*Reader Service No. 103*). Stated applications for the columns include gel filtration, ion exchange, hydrophobic interaction and affinity chromatography. The columns are available in lengths ranging from 5 to 120 cm. Flow adapters can be supplied for columns of 1.0-, 1.5- and 2.5-cm diameter. Plasti-Flex columns are, says Kontes, typically used in aqueous mobile phases at pressures of one bar or less. For easy and secure connection to reservoirs and tubing, the column's polyethylene reservoir cap and bed-support cap have integral polypropylene luer-lock fittings.

For temperature control from 5 °C above ambient to 150 °C, Eldex Laboratories offers a new **chromatography column heater** (*Reader Service No. 104*). The heater can hold up to four 30-cm length columns plus guard columns. To accommodate columns of all sizes, Eldex provides an assortment of interchangeable column inserts. The heater unit is insulated to protect the heater's outer casing and to maximize temperature stability, says Eldex. An injector valve can be installed for the preheating of samples.



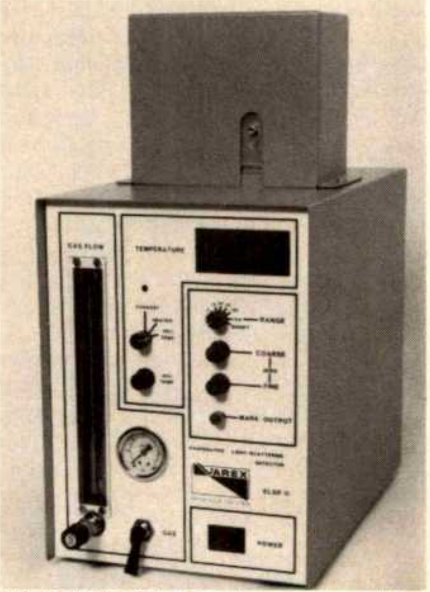
Eldex column heater — heats to 150 °C.

Solvent degassing, an important step for achieving clear chromatographic separations, need not be a problem with Knauer's **on-line degasser for HPLC** (*Reader Service No. 105*). Degassing is particularly important when using RI detectors, which are highly sensitive to undefined gas contents of solvents, says Knauer. Dissolved gases can cause micro bubbles in the pump and detector, which can result in baseline drift. Using Knauer's method, which the company claims is less expensive than helium degassing and more efficient than ultrasonic methods, the solvent to be degassed flows through a gas-permeable Teflon membrane system contained within a vacuum chamber. The pressure differential causes the gas molecules to escape through the Teflon membrane. According to Knauer, the slower the solvent passes through the membrane system, the more efficient the degassing process. Up to three channels with a flow rate of 5 ml min^{-1} each can be used for either one gradient system or three isocratic systems.

Detection systems

Wyatt Technology has launched the new Wyatt/Optilab 903 **interferometric detector** with nanogram sensitivity in most HPLC applications (*Reader Service No. 106*). The 903 can be used for on-line operation by coupling it to any HPLC or GPC/SEC line, or any other light-scattering detector, to create a powerful macromolecular characterization system. Conventional RIs require recalibration after a solvent change is made because of temperature instabilities, but the 903 eliminates the problem by using a circulating water bath as a heat exchanger. Wyatt's 903 detector can also be used for off-line operation as a differential refractometer to determine the specific refractive index increment, *dn/dc*. In this case, it is used in conjunction with a light-scattering detector for the determination of absolute molecular weights of dilute polymer solutions.

Universal mass detection of surfactants, lipids, carbohydrates, polymers and petroleum additives can be achieved with the Varex **laser light-scattering detector** for liquid chromatography — the LLSD MkII — from P.S. Instruments (*Reader Service No. 107*). Designed to link up to an LC separation system, the mass detector has stated applications in HPLC, gel permeation, size exclusion or supercritical fluid chromatography. The detector has, says PSI, particularly high sensitivity to compounds with specific functional groupings or chromophores. High stability and a 'noise-free' baseline performance in gradient elution analyses makes the LLSD MkII detector a useful general-purpose detector when compared with RI detectors.



P.S. Instruments' general-purpose laser light-scattering detector.

Instrumental ideas

Hewlett-Packard, in extending its modular HPLC instrument range, has introduced **titanium HPLC systems** — HP 1050 Ti Series — designed for chemical separations such as protein purification and ion chromatography that require the use of 'aggressive' mobile phases (*Reader Service No. 108*). The set-up includes a $6,850 (US) isocratic pump, $14,500 (US) gradient pump, $1,300–1,710 (US) manual injection valve option, $8,800 (US) autosampler and $6,250 (US) variable-wavelength detector. Titanium alloy is used to replace all conventional stainless steel parts in the instrument. The machine is particularly useful where formic acid in the mobile phase is required for the purification of hydrophobic proteins. Other uses include the purification of biologically-active materials when exposure to iron ions could inactivate enzymes, and where high salt concentrations are necessary to achieve sufficient column selectivity. To prevent 'cracking' associated with stress corrosion of pure titanium, the HP 1050 series contains 0.2 per cent palladium. Although the use of titanium increases prices, this, says Hewlett-Packard, can be offset against the machine's high resistance to corrosion.

Titanium HPLC modules from HP are built to resist corrosive solvents.

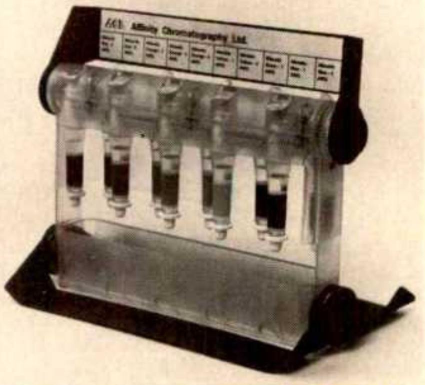
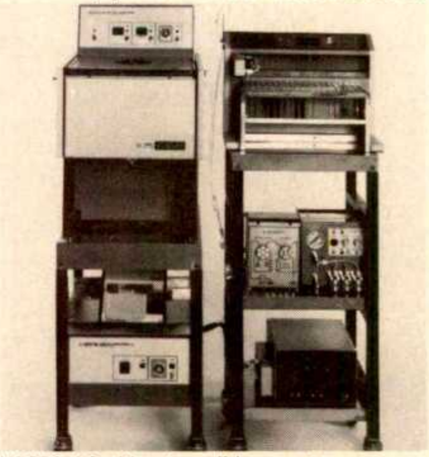
Reader Service No.56

Affinity Chromatography, located in the Isle of Man, has introduced an integrated PIKSI module (Protein Identification Kit by Sorbent Isolation) for purifying proteins by **affinity chromatography** (*Reader Service No. 109*). The module contains ten mimetic affinity ligands bonded to six per cent cross-linked agarose. This arrangement is designed to maximize the purification of most proteins in just a few minutes. No knowledge of the protein's molecular weight or isoelectric point is necessary. Mimetic ligand adsorbents are available in laboratory packs or in bulk quantities.



ACL's PIKSI affinity chromatography module.

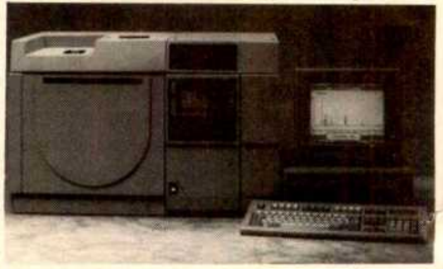
Sanki Laboratories is supplying a new modular system — the LLN-9 — for preparative/analytical **high-performance centrifugal partition chromatography** (HPCPC) (*Reader Service No. 110*). HPCPC uses liquid-liquid partition, countercurrent distribution to fractionate complex mixtures of chemical substances. Stated applications include the separation and purification of a broad range of synthetically and naturally-occurring chemical species, with particular use in the isolation of polar substances and biological materials — natural products, pharmaceuticals, biopolymers, antibodies and genetically-engineered molecules. As HPCPC does not use a solid stationary-phase support, irreversible retention of highly-retentive sample components is eliminated. Stationary-phase solvents are retained in the column by centrifugal force; this allows the use of high mobile-phase flow rates, without an appreciable loss of resolution, says Sanki.



HPCPC: LC without a solid support.

The DX-100 is an integrated, single-channel **ion chromatograph** from Waters designed to perform all types of isocratic IC separations using conductivity detection (*Reader Service No. 111*). Waters says that for analysts considering purchasing an add-on conductivity detector to an HPLC system, the dedicated DX-100 complete IC system, with no extra pumps or valves needed, is a useful alternative. The DX-100 uses advanced conductivity detection and offers 11 operating ranges from 0.01 to 1,000 μs full scale. The 4,000 psi-rated solvent-compatible pump has a 0.5–4.0 ml min^{-1} flow range with user-selectable high- and low-pressure alarms. All high-pressure flow paths are constructed of PEEK (polyetheretherketone) components for compatibility with the acids and bases used in IC. The £9,550 (UK) DX-100 IC system can be equipped with OmniPac and IonPac columns.

The PU4410 is the latest all-purpose **gas chromatograph** from Philips that is suitable for both capillary analyses and conventional packed-column chromatography (*Reader Service No. 112*). As the PU4410 is configured for increased throughput and ease of use, parameters are entered by a membrane keyboard, which is designed to guide the user through the process. Operation is simplified still further with the stopwatch, flow calculator, auto-start and parameter-locking facility. Included in the package are two capillary injectors — one split-splitless, the other a programmable thermal vapouriser injector. Other injectors are available for all types of capillary, 530 μ and packed-column studies. Five types of detector are offered, optimized, says Philips, for capillary chromatography and offering fast response times and small dead volumes. In need of help, well Philips offers a chromatography customization service to cater for all user needs. □



PU4410 GC system suits both capillary and packed-column analyses.

These notes are compiled by Diane Gershon from information provided by the manufacturers. To obtain further details, use the reader service card bound inside the journal. Prices quoted are sometimes nominal, and apply only within the country indicated.

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

Nature is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature*'s staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully.

Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

CATEGORIES OF PAPER

Review Articles survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

News and Views articles are intended to inform nonspecialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

Colour Artwork. A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

Abbreviations, symbols, units and Greek letters should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

Acknowledgements should be brief. Grant numbers and contribution numbers are not allowed.

***Submission.** All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT).*

CANCELLATIONS MUST BE RECEIVED NO LATER THAN 5PM ON THURSDAYS PRIOR TO ISSUE DATE.

ASSISTANT PROFESSOR, MICROBIOLOGY

The Department of Microbiology and Immunology, University of North Dakota School of Medicine invites applications for a tenure track position at the rank of assistant professor. Candidates should have a PhD and postdoctoral experience. The appointee is expected to develop a competitive research program, participate in the teaching of medical and general microbiology and develop a course in his/her specialty. Although research involving a molecular approach to microbial pathogenesis, microbial biochemistry/physiology or environmental microbiology is preferred, other research areas will be considered. Review of applications will begin 1, August 1990.

Applicants are to provide a letter of application, curriculum vitae, a statement of research with representative publications and the names, addresses and phone numbers of three references from whom the applicant has requested letters to: **Dr. James J. Kelleher, Chairman, Department of Microbiology and Immunology, School of Medicine, University of North Dakota, Grand Forks, ND 58202.**

UND is an Equal Opportunity/Affirmative Action Employer.

(NW5496)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF IMMUNOLOGY

Research Assistant

Research Assistant is required on a Medical Research Council supported grant for three years in order to investigate immunological defects in HIV infections. The technical skills necessary for this position include isolations of lymphoid populations by fluorescence cytometry and depletion techniques, investigation of lymphocytes by immunofluorescence and the analysis of the functional performance of cells taken from HIV infected individuals. Further skills in HIV viral isolation would be an advantage.

Salary on Research Scale 1B plus £1,767 London Allowance.

Application by curriculum vitae (2 copies) plus names and addresses of 2 referees to the **School Office, RFHSM, Rowland Hill Street, London NW3 2PF (tel: 071-794 0500 ext 4262).** Please quote ref: IMM/RA/113. Closing date 20 July 1990. (4058)A

Glaxo IMB

GLAXO INSTITUTE FOR MOLECULAR BIOLOGY

The Geneva molecular biology research institute of one of the world's most successful healthcare groups is recruiting a

CELLULAR NEUROBIOLOGIST

The successful candidate will join a highly motivated team of 30 molecular and cellular biologists and biochemists studying the structure/activity relationships of neurotransmitter receptors, and factors involved in nerve cell proliferation and differentiation.

The candidate is expected to have a PhD, and several years of postdoctoral research experience in neuro-cell biology with, if possible, experience in cell line Immortalization. The candidate's experience should be demonstrated by a significant list of publications.

The Glaxo Institute for Molecular Biology carries out long term research to support the company-wide effort to discover effective new medicines. It provides a dynamic research environment, and encourages the publication of scientific results as well as collaborative projects with academic groups.

We offer an excellent salary and benefits package and opportunities for career development in one of the most attractive parts of Europe.

If you are interested in this position, please send your Curriculum Vitae with a list of publications and the names of three referees to : Rita Gloor, Personnel Manager, GLAXO IMB S.A., 46, route des Acacias, 1211 Geneva 24, Switzerland.

新薬の探索・開発研究に意欲ある研究者求む

ファイザー製薬は世界の総合製薬企業ファイザーグループの重要な一員として、新薬の研究から生産・販売に至るまで日本で積極的に活動しています。

その研究活動の中心は名古屋市の南35㎞にあります。ここにはファイザー名古屋中央研究所と新薬開発センターの２つの研究所があり、新薬の探索から開発まで幅広く研究しています。

ファイザー製薬は日本での研究をさらに拡大・強化するために、以下の分野で博士の学位を有する人または同等の能力・経験のある独創的研究者を求めています。また国内外で博士研究員または企業での研究経験のある人、英語に堪能な人は特に歓迎します。

探索研究——ファイザー名古屋中央研究所

●生物科学部門

生化学・免疫学

サイトカイン、細胞表面受容体、炎症細胞の活性化等に研究経験のある人。炎症における種々のメディエーターの役割を解明する評価系を考案し実施する知識と経験のある人。

薬理学

種々の炎症に関する動物モデルに研究経験のある人。自己免疫、関節炎等の動物モデルの開発、一般薬理、細胞免疫に知識のあることが望ましい。

●合成部門

有機合成化学

有機合成反応および有機天然物合成の分野で研究経験豊かな人。生理活性物質のデザインとその合成の実施。薬物の生物学的側面について強い関心があることが望ましい。

●微生物部門

発酵・微生物学

微生物の分類、および微生物の発酵生産能力を制御することに研究経験のある人。

生化学・分子生物学・薬理学

疾病の発症機構の中に標的を選び出し、免疫学や分子生物学等の原理で評価系を確立することに必要な知識・経験のある人。

天然物化学

微生物由来の生理活性物質の単離・構造決定に経験豊かな人。

開発研究——新薬開発センター、医薬開発統括部

●製剤研究

経口および非経口製剤の処方研究、ＤＤＳ手法を用いた研究に経験豊かな人。

●薬物動態研究

薬物の代謝研究、薬動力学、統計解析に理解が深い人。

●薬理研究

炎症・免疫領域の種々の動物モデルや免疫担当細胞を用いる薬理・生化学。循環系、体液調節系、中枢神経系領域の薬理学、電気生理学および行動薬理学。

●細菌学的研究

各種抗菌剤の薬効評価およびその作用機序の研究。

●安全評価研究

動物での安全性評価研究、特に組織病理学に理解が深い人。

●臨床開発研究

循環器、免疫、炎症等に関する広範囲な薬剤の臨床開発を大学病院等医療機関と共同で推進する。関連各分野の基礎または臨床薬理の知識と臨床開発経験のある人。

応募者は履歴書、研究歴（研究業績・論文リスト）等を下記あて郵送下さい。秘密は厳守します。

MRC AIDS DIRECTED PROGRAMME

Research Scientists

Celltech's gene cloning and purification development teams have a collaborative research programme to express HIV-1 and SIV envelope proteins (gp120) in mammalian cells and to investigate the role of envelope transmembrane domains in the oligomerisation of gp160.

We have positions available on this programme for two post-doctoral scientists, initially for two years. If your experience and interests include expression, purification and characterisation of recombinant proteins – with specific reference to virus entry – this is your opportunity to join some of the UK's most exciting medical research projects. The research is supported by the MRC; you will work in a multi-disciplinary environment and enjoy extensive access to the MRC ADP network of academic research workers.

Cell/Molecular Biologist

You will generate stable cell lines expressing recombinant env proteins; experience in the HIV/SIV field would be desirable but is not essential. Ref: 449.

Protein Biochemist

You will need experience of protein purification, characterisation and assay development. Previous experience with viral structural proteins would be advantageous. Ref: 450.

Both positions offer highly competitive salaries, supported by comprehensive benefits packages.

Please write, with full details of your qualifications and experience, to The Recruitment Officer, Personnel Department, Celltech Limited, 216 Bath Road, Slough, Berkshire SL1 4EN, quoting the appropriate reference number.

(4100)A

CELLTECH

UNIVERSITY OF CAMBRIDGE

RESEARCH ASSISTANT

IN BIOCHEMISTRY & HUMAN MOLECULAR GENETICS

Applications are invited from graduates in biochemistry or molecular biology for a position funded for up to 4 years by the Wellcome Trust. The research will principally involve the characterization of the molecular defect in families infected by inherited disorders of metabolism.

It is planned to investigate the enzymatic defects at the level of protein and gene and to determine the precise effects of mutations by analysis of the variant proteins in expression systems. The research will involve biochemical analysis and molecular biology technology.

The salary will be in the range of £9196 to £12381 (under review).

Applicants should send 3 copies of their curriculum vitae and request further particulars from: **Professor T. M. Cox, Department of Medicine, Level 5, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QQ.**

The University follows an equal opportunities policy. (4084)A

JOHN INNES INSTITUTE

DEPARTMENT OF APPLIED GENETICS

A Scientific Officer/Higher Scientific Officer is required to join a group exploiting molecular techniques to study the population and evolutionary genetics of nitrogen fixing bacteria. The person appointed will assist in the isolation, culture and characterization of the bacteria and in analyses of particular DNA sequences.

Candidates should have a degree in an appropriate subject (in particular genetics or molecular biology) and for appointment to the higher level candidates should have at least five years post qualifying experience.

Salary at Scientific Officer level will be on the scale £9,131 to £12,223 and at Higher Scientific Officer level £10,678 to £14,909. Non-contributory superannuation.

Applications with full particulars and CV together with the names of two referees should be sent to the **Personnel Officer, John Innes Institute, John Innes Centre for Plant Science Research, Colney Lane, Norwich NR4 7UH.**

Closing date for applications 3rd August 1990 quoting reference AG/433.

The John Innes Institute is an Equal Opportunities Employer and is associated with the AFRS Institute of Plant Science Research.

(4061)A

MEDICAL RESEARCH COUNCIL
NATIONAL INSTITUTE FOR MEDICAL RESEARCH

Applications are invited for an

INDEPENDENT SCIENTIFIC POSITION

(five-year)

within a newly-established molecular immunology team at the Institute with special interest in thymus development, T-cell differentiation and tolerance induction. The candidate will be expected to establish a research programme in one of the above topics and therefore experience in cellular and/or molecular immunology research is essential.

The position is available immediately. The salary will be in the range £12,381 to £20,469 (starting salary dependent on experience) plus £1,767 per annum London Allowance. MRC Pension Scheme option.

Applications including a curriculum vitae, list of publications and the names and addresses of two professional referees should be sent to **Mr C R Russell, Administrative Manager, National Institute for Medical Research, The Ridgeway, Mill Hill, London, NW7 1AA**, not later than 3rd August 1990 *quoting reference number GSE/0250.* Informal enquiries about the nature of the work may be made to Dr Dimitris Kioussis on 081 959 3666 extension 2113.

The MRC is an Equal Opportunities Employer. (4106)A

MRC
Medical Research Council

University College London

Department of Geological Sciences

Postgraduate Unit of Micropalaeontology

LECTURESHIP IN PALYNOLOGY

Applications are invited from active research workers with interests in the fields of palynology, palynostratigraphy and palynofacies who will complement the scientific activities of the Department (which particulary concern post-Palaeozoic sequences) in addition to developing their own area of speciality; an interest in and experience with image analysis technology will be advantageous. The successful candidate will be expected to supervise research students in the Micropalaeontology Unit, participate in the M.Sc. Micropalaeontology Advanced Course, and contribute to Departmental undergraduate teaching. The appointment will be amde from 1 October 1990.

Salary within range £12,225–£22,236 p.a. inclusive according to age and experience.

Further information can be obtained from **Dr. A.R. Lord, Departmental Administrator, Department of Geological Sciences, University College London, LONDON WC1E 6BT.** Tel: 01-387 7050 ext. 7131. The closing date for applications is Friday 27 July 1990. *Equal Opportunities Employer.* (4055)A

5-HT Research

Two stimulating and varied opportunities

The formation of SmithKline Beecham has created a powerful force in the pharmaceutical world; a company with established global success to build on and now better equipped than ever to invest in the research and development of a substantial drug portfolio.

The climate is one of progress and change, thus it is an ideal time to join us. We are currently seeking scientists to consolidate our existing team of highly-innovative researchers in the 5-HT area.

Postdoctoral Fellow in Chemistry

This position, which is tenable for 2 years, offers an excellent opportunity for acquiring synthetic and medicinal chemistry experience in a major drug discovery area. Applicants should have a PhD with experience in heterocyclic chemistry and an interest in rational drug design. Proven technical and creative abilities as well as good communication skills are essential. Ref: 28/90.

Graduate Pharmacologist

We require a graduate to design and carry out vascular and biochemical studies, including exploratory research and screening. Applicants should have a good degree in Pharmacology or Biochemistry and some experience in Cardiovascular and Receptor Pharmacology. Experience in the use of computers for data analysis would be an advantage. Ref: 26/90.

We offer good career development opportunities in a stimulating work environment and excellent research facilities. In addition to a competitive salary, other benefits include a performance-related bonus scheme, free life assurance, medical insurance scheme, flexible working hours and subsidised sports, social and canteen facilities. Relocation assistance will be given where appropriate.

Please send your cv, quoting the appropriate reference, to Vance Frisch, Personnel Officer, SmithKline Beecham Pharmaceuticals, The Frythe, Welwyn, Herts AL6 9AR.

SB

SmithKline Beecham
Pharmaceuticals

(4077)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

MOLECULAR BIOLOGIST

A post-doctoral position funded for 3 years is available in a group interested in the cellular and molecular biology of bone cells. The project involves an analysis of regulatory mechanisms in osteoclastic development and function.

Salary on the 1A scale up to £18,432 per annum including London Allowance. To apply please send curriculum vitae and names of two referees to: **Professor T J Chambers, Department of Histopathology, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE**, 081 767 6954.

(4086)A

POSTDOCTORAL POSITION

Applications are invited for a postdoctoral position (2 years) in a research group studying genetics and regulation of virulence-associated properties in bacteria (*e.g. E coli* pili-adhesins, enterotoxins; for recent publications see: *Mol. Microbiol.* **3**, (1989) 1557. *Nature* **344**, (1990) 682).

PhD in biological sciences and experience in molecular genetics and biochemistry desirable.

Applicants should send curriculum vitae, statement of research interest, and a list of names and addresses of at least three references to:

Dr Bernt Eric Uhlin,
Department of Microbiology,
University of Umeå,
S-901 87 Umeå, Sweden

(W7517)A

FACULTY POSITIONS

DEPARTMENT OF BIOCHEMISTRY AND MOLECULAR BIOLOGY

THE UNIVERSITY OF CHICAGO

The Department of Biochemistry and Molecular Biology at The University of Chicago wishes to invite applications and nominations for several tenure-track positions to be filled in the 1990–1991 academic year. Candidates should have a doctoral degree, significant postdoctoral research experience, a strong record of research accomplishment, and demonstrable potential for the development of an independent research career in an academic setting. Although we are seeking individuals with research interests in any area of modern biochemistry and molecular biology, we are particularly emphasizing recruitment of individuals with research interests in nucleic acid biochemistry, protein-nucleic acid interactions, membrane and cell biochemistry, and structural biology, including magnetic resonance and molecular dynamics.

Applications should include a *Curriculum vitae*, a list of publications, a summary of current research activities and future research plans, and the names of at least four individiuals from whom letters of reference may be solicited. While we have no formal deadline, we would appreciate receiving applications by September 15, 1990. Please send applications or nominations to:

Marvin W. Makinen
Department of Biochemistry and Molecular Biology
The University of Chicago
Chicago, Illinois 60637

The University of Chicago is an affirmative action/equal opportunity employer.

(NW5500)A

British Antarctic Survey

HEAD OF UPPER ATMOSPHERIC SCIENCES DIVISION

CAMBRIDGE **SALARY UP TO £30,001**

The British Antarctic Survey initiates and conducts programmes of scientific research in Antarctica and its surrounding oceans and atmosphere.

The Head of Division has responsibilities for the planning, co-ordination and management of scientific research in Upper Atmospheric Science.

Duties include project planning, including aspects of financial, staff, technical and field operations management, as well as performance and productivity evaluation, control of allocated funds, recruitment, training and deployment of staff in the UK and Antarctica. The Head of Division will have direct responsibility for 27 scientists.

The Head of Division is expected to promote collaborative research with other institutions both nationally and internationally. An important element is to contribute to general policy development and administration of BAS. Current research programmes of the Division include energy flow and dissipation in geospace (involving Advanced Ionospheric Sounder and Anglo-American HF backscatter radar system for conjugate experiments, and future development of Automated Geophysical Observatories) and radio wave generation and propagation (ground and satellite experimental studies and theoretical modelling of wave-particle interactions, Whistler mode propagation, etc). The successful candidate will have a high international reputation in an appropriate field of upper atmospheric science and a proven track record of research management. Antarctic experience would be desirable.

The post is at Grade 6 level within the range £23,039 to £30,001 with further increments to £35,436 depending on performance. A non-contributory pension scheme is available.

Application forms are available from Mrs L. Nowlan, Natural Environment Research Council, Polaris House, North Star Avenue, Swindon, Wiltshire SN2 1EU. Telephone 0793 411531. The British Antarctic Survey is a component institute of the Natural Environment Research Council.

The closing date for applications is 26th July 1990.

University of Manchester
Department of Physiological Sciences
RESEARCH ASSISTANT

Applications are invited from recent or prospective graduates in biological sciences, biochemistry or a related subject, to work on molecular biological aspects of neuropsychiatric diseases. The post is available from October 1st, 1990 for 3 years in the first instance. Practical experience in basic molecular biology techniques would be an advantage. The appointee will be encouraged to study for a higher degree. Salary will be in the range £9,816 – £12,381 p.a. (under review) depending on qualifications and experience.

Please apply in writing, enclosing a full CV, to **Professor F. Owen, Department of Physiological Sciences, Stopford Building, the University, Manchester M13 9PT.** Closing date: August 17th 1990.

The University is an Equal Opportunity Employer. (4069)A

Postdoctoral Position
Biochemistry Department
University of Illinois at Chicago

A funded postdoctoral position is available to study transcriptional regulation of lipid metabolism in Drosophila. Candidates should have a recent Ph.D. and a background in molecualr biology or genetics.

Please contact Dr. Hoshizaki at 312/996-5112 and send résumé with the names of three references to:

Dr. Deborah K. Hoshizaki
Biochemistry Department (M/C 536)
University of Illinois at Chicago
1853 W. Polk St., Rm. A-312 CMW
Chicago, IL. 60612. (NW5507)A

POSTDOCTORAL POSITIONS

Available immediately at The Biomedical Research Centre on The University of British Columbia campus:

With Dr. Reudi Aebersold in:

1. Analytical Protein Chemistry: Development of improved technologies for protein sequence analysis.
2. Biochemistry/Molecular Biology: Characterization of protein kinases and their substrates in T lymphocytes using biochemical and molecular genetic technologies.

With Dr. Ian Clark-Lewis in:

1. Protein-Structure Function: Structure-function analysis of protein growth factors and cytokines using cloning, and chemical (peptide) synthesis.
2. Engineering of cytokine receptors: Cloning, mutagenesis and mammalian expression, purification, structural and functional analysis.

Applicants should send a curriculum vitae and the names, addresses and phone numbers of 3 referees to: **Dr. Aebersold or Dr. Clark-Lewis:**

University of Düsseldorf, Neurobiology Laboratory, Department of Neurology
MOLECULAR/CELL BIOLOGISTS and PROTEIN BIOCHEMIST

Applications are invited for postdoctoral research associates to join the Molecular Neurobiology Research Group working on the cloning, expression and regulation of genes relevant to nerve regeneration and on the biochemical characterization and function of glial growth factors in the central nervous system. Salary according to age and qualification (65,000-75,000 DM p.a.).

Send letter of application with full CV, summary of research interest and names of two referees to: **H. W. Müller, PhD, Department of Neurology, University of Düsseldorf, Moorenstr. 5, D-4000 Düsseldorf, Germany.** (W7516)A

INSTITUTE OF OPHTHALMOLOGY
(University of London)
Judd Street, London WC1H 9QS
Tel: 071-387 9621 ext 253

RESEARCH ASSISTANT

required to join a group based in the Department of Pathology located at Cayton Street, London EC1, working on autoimmune mechanisms in ocular disease. Previous experience in immunology helpful and training can be given in molecular biology. The ability to work as part of a team is essential. Salary in the range £11,583 – £14,148 (including LA) according to age and qualifications. The appointment will be for three years in the first instance. Candidates should send a cv and the names of three referees to **Miss Audrey Jones, Assistant Secretary,** at the above address. Closing date 19 July 1990.
(4054)A

Parke Davis Research Unit, Cambridge.

DIRECTOR: DR JOHN HUGHES

RESEARCH ASSOCIATES IN PHARMACOLOGY

This unique Unit is developing new generation drugs for the treatment of nervous and neurohormonal disorders. Our basic research interests centre on the function and mechanism of action of hormones and neurotransmitters at the behavioural, cellular and molecular levels with particular reference to peptides. We have a number of strong research programmes involving permanent staff, Ph.D. students and Post-doctoral Fellows. Collaborative projects with several University, Research Council and Hospital research groups are also in progress.

As part of an expansion of our facilities in Cambridge, we have vacancies for young graduate pharmacologists. Applicants should be recent graduates in pharmacology or a closely related subject. Experience of working in a research laboratory in industry would be an advantage. The positions, which are available immediately, carry a starting salary in the range £11,462 to £13,111 on a scale rising to £23,167. Starting salary will be dependant on qualifications and experience. Other benefits include lunch allowance, Christmas bonus, contributing Pension Scheme, life assurance and relocation assistance where appropriate.

Applications should be accompanied by a full up-to-date curriculum vitae, together with the names of two referees, and sent to:

Dr. Chris Bruton,
Head of Administration & Personnel,
Parke Davis Research Unit,
Hills Road,
Cambridge CB2 2QB

to arrive as soon as possible and in any event by 27th July 1990.

LAMBERT

(4107)A

The University of Queensland

Equal Opportunity in Employment is University Policy

Chair of Geology and Mineralogy

Applications are invited for the Chair of Geology and Mineralogy from geoscientists of high academic standing with substantial research achievements. The appointee will be strongly committed to education in geology at all levels; have considerable teaching and administrative experience, and a demonstrated capacity for collaboration with industry and the attraction of external funds.

It is expected that the appointee will assume significant administrative responsibilities, including the Department Headship for at least the first five years of appointment.

In addition to the advertised chair, the Department has 14 full-time teaching staff positions, including the **Dorothy Hill Chair of Palaeontology and Stratigraphy**, and 21 research and support staff. The Department has excellent research facilities for a range of disciplines including petrology, elemental and stable isotopic geochemistry, palaeontology, sedimentology, and geophysics; a museum and a first-class library. The **W H Bryan Mining Research Unit**, housed within Geology and Mineralogy, is a recent joint venture with the Department of Mining and Metallurgical Engineering.

The Department offers 3 and 4-year (Honours) courses leading to the BSc degree in Geology, 4-year courses leading to Bachelor of Applied Science (Geophysics) and Bachelor of Bachelor of Applied Science (Geology), and coursework leading to Master of Scientific Studies. There are currently 41 postgraduate students, of whom 21 are PhD or research MSc candidates.

The salary for a Professor is A$67,812 per annum. **Ref. No:** 23990. **Closing Date:** 31 August 1990.

Further information is available from the Head of Department Dr G R Orme on (07) 377 3910.

Application forms and further details concerning method of application are available from the Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London, WC1H OPF. (W7445)A

COMMONWEALTH SECRETARIAT

SCIENCE ADVISER

Applications are invited for the post of Science Adviser to the Commonwealth Secretary-General. The Science Adviser is also Secretary of the Commonwealth Science Council (CSC) which aims to enhance scientific and technological capability in Commonwealth countries by enabling them to undertake research and training to solve development problems. The Science Adviser/Secretary CSC who leads a small team of scientists and supporting staff advises the Secretary-General on the scientific and technological implications of the Secretariat's programmes in the context of global issues and trends, the improvement of indigenous technologies and the identification of areas of innovation. He/she will be responsible to the CSC for the planning, management and control of CSC programmes, budgetary and staff matters. Considerable travel may be involved. Applicants, who must be Commonwealth citizens, should have a doctoral-level degree or equivalent qualification in science or engineering, with experience in post-doctoral research and the planning and management of applied science and technology. Applicants must demonstrate capacity for innovative planning and independent action, should have a general awareness of the emerging scenarios in science, technology and environment, and be conversant with the broad lines of science policy and research, especially in the Commonwealth, sources of expertise and of funding. The Adviser/Secretary CSC is required to function effectively in a multi-cultural environment. As an equal opportunity employer, the Secretariat specially welcomes applications from suitably qualified women.

Appointment is for two to three years initially. Salary range £30,228-£35,448 pa gross plus for UK resident 12 ½ per cent salary and for overseas appointee expatriation and other allowances. Job description and further details available on request. Please send detailed CV, quoting ref ON 37/90, with names and addresses of three referees by 7 September 1990 to the **Chief Personnel Officer, Commonwealth Secretariat, Marlborough House, Pall Mall, London SW1Y 5HX. Telephone No 071-839-3411 extension 8153 or 8134, fax 071-930-0827.**

AN EQUAL OPPORTUNITY EMPLOYER (4080)A

Graduate Scientist

The National Radiological Protection Board is the major point of reference for radiological protection in the UK, providing advisory and technical services to users of radioactive materials and those with responsibilities for Radiological Protection in industrial, medical, research and teaching situations.

A vacancy exists in the Biomedical Effects Department for a postdoctoral or graduate research scientist to carry out work on the placental transfer and fetal accumulation of radionuclides and their effects, as part of the Department's evaluation of occupational and environmental exposure to radioactive materials.

The successful candidate will carry out an experimental programme and contribute to the development of models to assess *in utero* radiation doses and carcinogenic risk. He/she may be involved in more general studies of the behaviour of radionuclides in the body.

Applicants should possess research experience in animal physiology with an interest in, and knowledge of, embryology and developmental biology.

The appointment will be in the grade of Higher Scientific Officer with a starting salary within the range £10,875-£16,590pa depending on age, qualifications and experience.

Application forms can be obtained from Establishments and Personnel Branch, National Radiological Protection Board, Chilton, Didcot, Oxon. OX11 0RQ, or telephone Abingdon (0235) 831600 exts. 2553/2548, quoting ref: PER/A324. Closing date for receipt of completed application forms: 20th July 1990. (4083)A

NRPB

National Radiological Protection Board

THE ROYAL VETERINARY COLLEGE

(University of London)

POSTDOCTORAL RESEARCH ASSISTANTS

2 POSTS

Department of Veterinary Basic Sciences

Applications are invited for postdoctoral research assistants to work on each of the following projects:

1. 'Effects of environmental temperature on the development of tissue cellularity in the Atlantic Salmon'. Experience in tissue culture techniques would be an advantage.
2. 'The determination of muscle fibre number in the very early critical stages of gestation'. Experience in immunocytochemistry and molecular biology would be useful.

The appointments are grant-funded by the NERC and AFRC and are for 3 years. Both appointments are immediately available.

Salary is in the range £13,166 - £19,932 including London Allowance. Eligibility for the Universities' Superannuation Scheme.

Applications including C.V. and the names of three referees should be sent to the **Assistant Personnel Officer, The Royal Veterinary College, Royal College Street, London NW1 0TU. Closing date for application is 26 July 1990.** (4089)A

POSTDOCTORAL POSITION

A postdoctoral position is immediately available for recent or experienced PhD (genetics, biochemistry or equivalent training) to study th molecular basis of schizophrenia using linkage analysis. Experience in current molecular genetic techniques is prerequisite.

Send CV and three references to **Dr. N.P. Anagnou, Dept. Basic Sciences, University of Crete School of Medicine, 711 10 Heraklion, Crete, Greece.** FAX # (081) 233-669. (W7500)A

Novo Nordisk

Molecular Biologist

The CNS Division of Novo Nordisk has a new position available in the newly established Molecular Neurobiology Task Force.

The successful candidate will join a team of scientists engaged in basic research and drug discovery programs directed towards the identification of novel therapeutic approaches to CNS disorders such as epilepsy, ischaemia, anxiety and schizophrenia.

The candidate will concentrate on the molecular aspects of the research areas and will become a member of the Molecular Biology Task Group in the CNS Division.

Qualified applicants are expected to be at the Ph.D. level with experience in neuroscience. Familiarity with neuroanatomy, histology and histochemical techniques, especially in situ hybridization is preferred. Experience with blotting techniques, autoradiography and cell culturing is desirable.

Novo Nordisk CNS Division is located approximately 5 miles from Copenhagen.

Interested candidates should submit their curriculum vitae and description of research experience. Please mark the application "Histo.496".

Novo Nordisk A/S
Health Care Group
Krogshoejsvej 41
DK-2880 Bagsvaerd

Att.: Personnel Department

Novo Nordisk is one of the world's leading biotechnology companies. It is a major force in insulin manufacture and diabetes treatment and is the world's largest producer of industrial enzymes. The company also manufactures and markets a variety of other pharmaceutical and bioindustrial products. Headquartered in Denmark, Novo Nordisk employs more than 8.000 people in 30 countries.

(W7503)A

THE UNIVERSITY OF THE WEST INDIES
Mona, Jamaica

The University of the West Indies (UWI) is supported by fourteen English-speaking Caribbean countries. There are campuses in Jamaica, Trinidad and Tobago, and Barbados, and University centres in eight of the other contributing countries. The Mona Campus is situated in a valley near Kingston. There are, at present, 5,086 undergraduate and 586 postgraduate students on that campus.

The University has made the development of Science and Technology in the Caribbean region a priority and is encouraging the development and prosecution of major research programmes, and collaboration with governments and other institutions in the region.

The University is seeking candidates with a proven record of achievement for the following appointments, which will be on tenure or tenure track.

PROFESSOR IN THE DEPARTMENT OF BOTANY

The Botany Department has a complement of seven academic staff and trains students for the BSc, MPhil and PhD degrees. Facilities include a tissue-culture laboratory, three greenhouses, an experimental field and a scanning electron microscope. The Department can share other facilities located within two Marine Laboratories, a Biotechnology Centre, and a Reactor Centre. This provides access to additional major items of equipment. The Campus computer is an IBM 4381 mainframe. Funding for other equipment and additional recurrent is being pursued. The Science Library has 40,000 volumes and over 1,500 subscriptions.

DIRECTOR OF THE CENTRE FOR MARINE SCIENCES
(PROFESSORIAL POST)

The Marine Sciences Centre is being developed from an existing Unit which is presently under the aegis of the Department of Zoology, Faculty of Natural Sciences. It will undertake research and training taking into account the special circumstances of the Caribbean and provide a forum for information exchange on marine science related activities. The activities are mainly carried out in two Marine Laboratories; one at Port Royal on the south coast, and the other at Discovery Bay on the north coast. The Centre will benefit from the common services and facilities of the Faculty on Mona campus.

PROFESSOR IN THE DEPARTMENT OF ZOOLOGY

The Zoology Department has a complement of fourteen academic staff members. The Department trains students for the BSc, MPhil and PhD degrees; and currently there are 478 undergraduate and 32 postgraduate students enrolled. The Department is well housed and equipped.There is a marine laboratory, which includes a newly constructed aquaculture laboratory, on the south coast; and another at Discovery Bay on the north coast. Facilities include electron microscopes; other central facilities include an Analytical Laboratory, a Neutron Activation Laboratory, and an Electronics Maintenance and Design Centre. The Campus computer is an IBM 4381 mainframe. Funding for other equipment and additional recurrent is being pursued.

GENERAL

Appointees will be expected to contribute significantly to the development of their discipline and to lead major research programmes. The University will make every effort to provide the appointees with funding for postdoctoral fellowships, research assistants, research students, and for conference travel. Fund raising through grants will be encouraged. Comfortable housing will be provided at nominal rental and other attractive perquisites are offered. Consultancy is allowed within the University rules.

Interested persons are invited to apply to the **University Registrar, University of the West Indies, Mona, Kingston 7, Jamaica,** from whom further particulars are available. Applicants should submit full curriculum vitae and outline their present main field of research and programmes they would wish to pursue at UWI. The names and addresses of three referees should also be included. Further particulars of the posts are also available from the **Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, to whom candidates in the UK should also send one copy of their application.** (W7510)A

POSTDOCTORAL RESEARCH AT THE NATIONAL CENTER FOR TOXICOLOGICAL RESEARCH

Research efforts at NCTR, an FDA laboratory in central Arkansas, focus on testing the assumptions used in assessing risks posed by toxic chemicals emphasizing studies in biomarkers, modulators of toxicity, and extrapolation/risk assessment. Postdoctoral stipends begin at $31,750 per year. U.S. citizenship or PRA status required. Contact:

Postgraduate Research Program at NCTR,

POSTDOCTORAL FELLOW

$A32,472-$A39,724

LABORATORY FOR MOLECULAR BIOLOGY
DIVISION OF BIOMOLECULAR ENGINEERING,
NORTH RYDE, AUSTRALIA

We have a position for a Molecular Virologist:

THE JOB: The successful applicant will be required to work on the development of an ovine viral vector system for the delivery of recombinant vaccine antigens. Experience in recombinant DNA technology, preferably in the manipulation of viral genomes and in cell transfection and the analysis of gene expression are desirable. Skills in the growth and maintenance of viruses in tissue culture would be an advantage.

THE PERSON: Applicants should possess a PhD or equivalent qualification in virology or molecular biology and should, preferably, be able to take up the appointment by 31/10/90.

CONDITIONS: Appointment will be for a term of three years with Australian Government superannuation available.

MORE INFORMATION; Prospective applicants are invited to write to or telephone Dr. G. Both on (02) 886 4888 for further information. Selection criteria are available from Ms. Maree O'Neill on the same number.

APPLICATIONS: Applications quoting reference PG1/60 should be submitted by 27/7/90. They should be framed against the selection criteria and should state relevant personal particulars including details of qualifications and experience. Applicants should nominate and provide fax numbers for at least two professional referees and address their applications to:

The Chief,
Division of Biomolecular Engineering,
Laboratory for Molecular Biology,
P.O. Box 184,
North Ryde NSW 2113, Australia.

CSIRO

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER AND PROMOTES A SMOKE FREE ENVIRONMENT (W7505)A

PERMANENT TRACK (ASSISTANT/ASSOCIATE or FULL PROFESSOR)

position in developmental immunology and/or immunological aspects of hematopoiesis. Successful applicants will be expected to develop outstanding independent research programs which could involve for example: B or T cell ontogeny, development of T cell repertoire, or cytokine regulation of lymphocyte development. Strong interest in graduate and postdoctoral education programs required. Highly interactive, academic immunology department of ten independent laboratories located within Mayo Clinic medical complex. Excellent laboratory facilities. Startup funds are available. Candidates with proven productivity and credentials please send curriculum vitae, statement of research interests, and names of three references to **Larry R. Pease, Ph.D., Department of Immunology, Mayo Clinic, Rochester, MN 55905.** *An equal opportunity/affirmative action employer.* (NW5464)A

UNIVERSITE DE LAUSANNE

The Medical Faculty of the Lausanne's University invites applications for two positions at its institute of microbiology

Professor of Microbiology with expertise in Virology

The professor will be the head of the Institute. Duties will involve the administration of the Institute, teaching to medical students and conducting research.

Professor of medical bacteriology

The professor will be the head of the division of medical bacteriology and diagnostic. Duties involve teaching to medical students and conducting research.

The appointed Professors are expected to be able to teach in french within two years from the date of appointment.

Applications including a curriculum vitæ, a short description of research perspectives, a list of publications and five reprints of the three most important publications should be submitted to: **Professor Y. Saudan, Dean of the Faculty of Medicine, University of Lausanne, rue du Bugnon 9, CH-1005 Lausanne,** by August 31st, 1990. From whom further information can be obtained. (W7508)A

International Research Laboratories (IRL)
CIBA-GEIGY (Japan) Ltd.

IRL is one of the fundamental research organizations of CIBA-GEIGY Group, established in 1986 in Japan. The total number of research scientist is about 80 at present, and will be further increased to 130 toward 1994 in the laboratories of Bio-organics, New Materials, Analytics & Informatics and Chemistry. Now, IRL offers:

One Postdoctoral Position
in the Research Field of
Signal Transduction Mechanism with Smooth Muscle Cells

for a period of one to two years
beginning in November or December 1990

Essential qualifications are:
A Ph.D., up to 35 years old
Of any nationality, but able to communicate in English and/or Japanese

Applications are invited immediately, to include curriculum vitae, a publication list and a concise description of interested research field to:
M. Shiono, Planning & Coordination, CIBA-GEIGY (Japan) Ltd., 10-66, Miyuki-Cho, Takarazuka, Hyogo Pref. JAPAN, Tel. 0797-74-2458, Fax. 0797-74-2325

(W7502)A

University of Glasgow Department of Surgery
and
Beatson Institute for Cancer Research

LECTURER

Applications are invited for a Lectureship in the Department of Surgery, Glasgow Royal Infirmary and for the appropriate candidate there will be an associate appointment with the Beatson Institute for Cancer Research. It is expected that the successful applicant, where applicable, will hold responsibilities on both sites and will be expected to take part in collaborative research between the two institutions in the field of molecular or cell biology of solid tumours.

The department of surgery has an active clinical programme in surgical oncology and has research interests in tumour cell proliferation and targeting of therapy to metastasis.

There is at present active collaboration in the fields of metastasis (with Dr. George Birnie) and carcinogenesis (with Dr. Allan Balmain). The successful applicant is not necessarily restricted to one of these areas, but it is hoped that they will take advantage of the close association between the two departments. There are extensive modern laboratory facilities within the department of surgery which are presently being re-equipped and, when appropriate, use can be made of the established facilities at the Beatson Institute together with some research support.

This appointment is for five years initially, and the salary range will be on the University non-clinical lecturer scale £12,086-£22,311.

Initial enquiries can be made to Professor T.G. Cooke, University Department of Surgery, Royal Infirmary, Glasgow. Tel: 041-552 3535 Ext. 5429 and further information can be obtained from Dr. John Wyke, Beatson Institute for Cancer Research, Switchback Road, Bearsden, Glasgow. Tel: 041-942 9361.

Further particulars may be obtained from the **Academic Personnel Office, University of Glasgow, Glasgow, G12 8QQ,** where applications (12 copies), giving the names and addresses of not more than three referees should be lodged on or before 4th August, 1990.

In reply please quote ref. no. 7008(M). (4075)A

HANNAH RESEARCH INSTITUTE
DEPARTMENT OF BIOCHEMISTRY & MOLECULAR BIOLOGY
RESEARCH ASSISTANT

Applications are invited from post-graduate or post-doctoral biochemists to work on a two-year project funded by the British Heart Foundation to investigate mechanisms involved in the control of the expression of HMG-CoA reductase (the rate-limiting enzyme for cholesterol synthesis) by Ca^{2+}-mobilizing hormones.

Salary will be up to £10,850 (increase pending) depending on qualifications and experience. Non-contributory pension scheme. HRI/189.

PHYSICAL CHEMISTRY GROUP
RESEARCH ASSISTANT — PhD OPPORTUNITY

A vacancy exists in the Physical Chemistry Group for a physical scientist to join a team studying the structures of gels and networks produced during the coagulation of concentrated colloidal dispersions. The research will involve development and application of novel laser light scattering and rheological techniques.

The post is a fixed term appointment available for 3 years. Applicants should possess a first or upper second class honours degree in Physics, Chemistry or a related subject. The successful candidate will have the opportunity to work towards the degree of PhD at the University of Glasgow.

The post is graded Scientific Officer. Salary Scale £9,131–11,192 per annum. Non-contributory pension scheme. HRI/190.

Further particulars are available from the Secretary, Hannah Research Institute, AYR KA6 5HL, to whom applications including the names and addresses of two referees should be sent by 27 July 1990 quoting the appropriate reference.

PHYSICAL CHEMISTRY GROUP AND UNIVERSITY OF DURHAM, DEPARTMENT OF CHEMISTRY
SERC/CASE POSTGRADUATE AWARD

Chemist with an interest in solid state NMR techniques required to work on the structure of amorphous and poorly crystalline biological calcium phosphates. Candidates should have a first or upper second class honours degree and will be registered for the degree of PhD at the University of Durham. Interested applicants should contact Dr C Holt (0292 76013) or Professor R K Harris (091 3743121). (4060)A

RESEARCH SCIENTIST/ SENIOR RESEARCH SCIENTIST

GEOPHYSICAL FLUID DYNAMICS

AUS $31,525 p.a. to $45,699 p.a.

INSTITUTE OF NATURAL RESOURCES AND ENVIRONMENT

DIVISION OF ATMOSPHERIC RESEARCH, MELBOURNE, AUSTRALIA

THE FIELD: Strait flows and Coastal Current Dynamics.

THE DIVISION: The Division of Atmospheric Research has a staff of 150 including 90 professional scientists and undertakes research into physical, chemical and dynamic aspects of atmospheric phenomena and related areas.

THE JOB: To undertake research into the character of the stratified Bass Strait overflow and its consequences for the Tasman Sea circulation and non-linear coastal hydraulics generally, using laboratory and theoretical techniques. Studies of coastal systems and boundary currents affected by both stratified or Rossby-wave hydraulics are planned as an extension of this work.

THE PERSON: Applicants should possess a Ph.D. degree or equivalent in geophysical fluid dynamics, together with experience, and aptitude for laboratory studies.

CONDITIONS: Appointment will be for a term of three years with Australian Government superannuation benefits available. Salary will be commensurate with qualifications and experience.

MORE INFORMATION: Prospective applicants are invited to contact the Division by telephone (613) 586 7666, facsimile (613) 586 7600, or telex AA34463, for a copy of the job description and selection criteria. Dr. Peter Baines may be contacted for further information.

APPLICATIONS: Should be submitted by the 31st July 1990 and quote reference AT9005. They should be framed against the selection criteria and should provide relevant personal particulars, including qualifications, transcripts of tertiary results and experience. Copies of one or two relevant publications by the applicant would be desirable. Applicants should nominate at least two professional referees and address their application to:

RESEARCH ASSISTANTS 1B

The research assistants (1B) are required to join an expanding group working on the physical mapping of the X-chromosome and on the study of mutations which causes the X-linked diseases haemophilia and muscular dystrophy. The work will be carried out under the supervision of Dr David Bentley and Professor Francesco Giannelli.

One post is available to develop and evaluate methods for automated analysis of DNA sequences, YAC and cosmid fingerprints and mutations, using fluorescent labelling technology. The other post is to assist in the development and implementation of procedures for isolating and analyzing YAC clones by both polymerase chain reaction (PCR) and hybridization-based approaches. The posts are tenable for three years.

For more information please contact Dr David Bentley on 071-955-4645.

Applications including a C.V. and names of three referees to **The Administrator, Paediatric Research Unit, Division of Medical and Molecular Genetics, 8th Floor, Guy's Tower, Guy's Hospital, LONDON SE1 9RT**, by 27th July. (4056)A

JCU JAMES COOK UNIVERSITY OF NORTH QUEENSLAND

GEOLOGY DEPARTMENT

(including National Key Centre for Economic Geology and Marine Geophysical Laboratory)

POSTGRADUATE RESEARCH TOPICS IN 1991

Applications are invited for postgraduate students to work with research teams in the following areas:

- Terrane analysis and geomorphic studies in the northern Tasman fold belt (Assoc. Professors R.A. Henderson and P.J. Stephenson)
- Structural controls on the localisation of ore deposits (Drs. T.H. Bell, S. Johnson and K. Lawrie)
- Field processes and the origin of ore deposits (Professor G.N. Phillips, Assoc. Professor R.G. Taylor, Drs. M.J. Rubenach, P. Williams and R. Myers)
- Effects of sea-level change on sedimentary facies (Professor R.M. Carter, Dr. C. Fulthorpe)
- Marine geoscience, including shelf studies and deep-ocean swathe mapping (Assoc. Professors D.P. Johnson and R.A. Henderson, Professor R.M. Carter, Mr. P. Larcombe)

Applicants should possess a high-quality honours or masters degree in geology or a related science. Australian nationals or residents are eligible for Australian Postgraduate Scholarship Awards (closing date 31 October annually). Overseas applicants from Europe and North America are eligible for Overseas Postgraduate Research Awards (closing date 28 September annually). Overseas students from most other countries may apply for Equity and Merit Scholarship Awards (closing date 31 May annually).

Further information available on individual research programs from any of the above research personnel, or the Director of Graduate Studies, Department of Geology, James Cook University, phone (077) 814536, facsimile (077) 251501.

Further details on Scholarships and method of application from **Postgraduate Admissions, James Cook University, Townsville Qld 4811, Australia,** phone (077) 814755, facsimile (077) 796371.

KUWAIT INSTITUTE FOR SCIENTIFIC RESEARCH

Kuwait Institute for Scientific Research (KISR) is a nonprofit organization with a staff of more than one thousand employees engaged in applied research in the fields of environmental and earth sciences; water resources; food resources; engineering; petroleum, petrochemicals and materials and techno-economics.

KISR requires a:

MOLECULAR GENETICIST

- **Major Duties:**
  Carries out extensive research on the genetic improvement of industrial microorganisms using recombinant DNA technology; develops advanced methods for cloning, analysis of gene expression in microorganisms and DNA/RNA probes.
- **Qualifications:**
  Applicants should have a Ph.D. in Molecular Genetics or Molecular Biology with a minimum 5 years experience in recombinant DNA technology. Experience in tissue culture techniques is desirable but not essential.

KISR offers attractive tax free salaries commensurate with qualifications and experience and generous benefits that include gratuity, free furnished air-conditioned accommodation, school tuition fees for children, contribution to a savings plan, six weeks annual paid vacation, air tickets, free medical care and life insurance.

Interested applicants are requested to send their Curriculum Vitae with supporting information not later than one month from the date of this publication, to:

Director General
Kuwait Institute for Scientific Research
P.O. Box 24885 Safat
13109 Safat — KUWAIT.

(W7509)A

Senior Pharmacologist

from £19,890 pa

Ware, Herts

Glaxo is Britain's premier pharmaceutical company, with a reputation for excellence in its research.

Success has brought an expansion of our research into disorders of the gastrointestinal tract and we are looking for a recent PhD in Pharmacology to join us.

Gastrointestinal Pharmacology is one of our newer departments but is already working on a broad range of important diseases. You would join a team researching peptide hormone receptors in the GI tract.

You should have a sound background in pharmacology and, ideally, experience of research on receptor classification. We're looking for someone with drive and commitment to achieving goals, as well as the ability to innovate - new medicines don't come easily. As a key member of a project team, you should be ready to take responsibility and to put forward ideas to the whole project group.

We're asking for a lot, but we've a lot to offer in return: good salary, with performance based increases, relocation assistance where appropriate, free pension, flexible hours, subsidised restaurant and sports and social facilities on site. We have the scientific facilities for you too - well equipped laboratories, library and information resources.

Send a CV, or write quoting ref NT 100 for an application form, to: The Research Personnel Officer, Glaxo Group Research, Park Road, Ware, Herts SG12 0DP.

Molecular Biologist

(Fixed-Term Contract)

Celltech is one of Europe's leading biotechnology companies, and a pioneer in the application of molecular biology to the discovery of new pharmaceutical products. We are looking for an experienced scientist to join our gene cloning team, on a fixed-term contract lasting up to one year.

This is an ideal opportunity to apply practical molecular biology skills in a results-driven industrial context – and make a key contribution to our advanced drug discovery programme. Ideally a PhD-qualified life-scientist, you must have at least three years' sound experience in molecular biology which includes relevant DNA cloning and sequencing work. Your practical scientific skills should be balanced by adaptability, initiative and good communication skills.

A highly competitive salary will be supported by a comprehensive benefits package.

Please write, with full details of your qualifications and experience, to The Recruitment Officer, Personnel Department, Celltech Limited, 216 Bath Road, Slough, Berkshire SL1 4EN, quoting reference EFW.

DIRECTOR HOLLINGS ONCOLOGY CENTER

MEDICAL UNIVERSITY OF SOUTH CAROLINA

The Director for a new cancer center to be established at the Medical University of South Carolina in Charleston will have a mission to develop and maintain a coordinated and multi-disciplinary center of excellence in cancer research, treatment and outreach.

The Hollings Oncology Center is a University Center on this campus and its planning and administrative oversight is by a university center planning and management group appointed by the President. Ground breaking for its separate building is in October, 1990.

The Candidate's background should include administrative experience commensurate with directing an academic department or institute and a record of outstanding achievement in clinical and research oncology.

Nominations and credentials including bibliography and curriculum vitae should be sent to **Edward, L. Hogan, M.D., Chairman, Search Committee for Director of Hollings Oncology Center, Office of the President, Medical University of South Carolina, Charleston, South Carolina, 29425.**

MEDICAL UNIVERSITY OF SOUTH CAROLINA
171 Ashley Avenue
Charleston, South Carolina 29425

An equal opportunity/affirmative action employer. Minority/female/handicapped/veteran. (NW5508)A

British Geological Survey

GROUNDWATER CHEMIST

A vacancy exists in the Survey's Hydrogeology Research Group based at Wallingford in Oxfordshire to join teams investigating and predicting the hydrogeochemical processes affecting groundwater quality and pollutant transport. The successful candidate will be involved in the interpretation of field and laboratory investigations of the behaviour of a variety of inorganic solutes and synthetic organic chemicals in the groundwater environment.

Applicants must be numerate and should have, or be obtaining, an honours degree in chemistry, chemical engineering, environmental sciences or geological sciences with a sound knowledge of chemistry.

The appointment will be for a period of three years with the possibility of extension.

Salary will be within the range £9,131 to £14,909 depending on experience and qualifications. Terms include a generous leave allowance and a non-contributory pension scheme.

For an application form, to be returned no later than 26th July 1990, write to:- Establishments (Recruitment), British Geological Survey, Keyworth, Nottingham NG12 5GG. Please quote reference no. SO/WL/90/2.

The Natural Environment Research Council is an equal opportunities employer.

PORTSMOUTH POLYTECHNIC

Biophysics Laboratories
School of Biological Sciences

LECTURESHIP IN PHYSICAL BIOCHEMISTRY/MOLECULAR BIOLOGY

REF. SCI 110

Applications are invited for a temporary Lectureship in the School of Biological Sciences. The post has been made available by the award of a Royal Society Leverhulme Trust Senior Fellowship to Dr. G. G. Kneale, and is available for one year from 1 October 1990.

The successful candidate will be expected to teach on the B.Sc. (Hons) degree course in Molecular Biology, including aspects of biophysics and physical biochemistry. There will also be the opportunity to become involved with current research in the Biophysics Laboratories, and candidates with interests in protein-nucleic acid interactions would be especially welcome.

Salary will be at an appropriate point on the Lectureship scale, currently £10,827-£16,521.

Application forms and further particulars are available from the **Personnel Office, Nuffield Centre, St. Michael's Road, Portsmouth PO1 2ED. Telephone (0705) 843257.**

Closing date for applications: 19 July 1990. (4093)A

Portsmouth Polytechnic pursues a policy of equality of opportunity. Applications are particularly welcome from people with disabilities.

Faculty Position

Department of Biochemistry

Stanford University School of Medicine

Application or nominations are invited for a faculty position in the Department of Biochemistry at the level of Full Professor.

Stanford University is committed to increasing representation of women and members of minority groups on its faculty and particularly encourages applications from such candidates.

Applicants should have an established record of excellence in original research and in teaching. Candidates should submit a *curriculum vitae* including a list of publications, a description of their research interests, and names, addresses and telephone numbers of three references to: **Search Committee Chairman, Department of Biochemistry, Beckman Center B400, Stanford University School of Medicine, Stanford, CA 94305-5307.** (NW5497)A

UNIVERSITY OF EDINBURGH
FACULTY OF MEDICINE
DEPARTMENT OF ANATOMY
NON-CLINICAL LECTURESHIP IN HUMAN ANATOMY

Applications are invited for a Lectureship which is available from October 1st 1990, in the Department of Anatomy under the University Funding Committee's new academic appointment scheme. Under the terms of this scheme, which is intended to provide permanent appointments for young staff, preference will be given to candidates at an early stage in their careers. The individual appointed should ideally be clinically qualified with some experience in the teaching of topographical anatomy. Candidates should preferably be familiar also with teaching of Histology, Neuroanatomy and Embryology and be actively involved in anatomically orientated, clinically relevant research. Medically or scientifically qualified candidates without a PhD or equivalent will be considered, as staff in post are encouraged to study for a higher degree or diploma.

Salary will be at an appropriate point on the Lecturer scale AT2A £12,086-£16,755 per annum. USS Superannuation.

Further particulars may be obtained from the **Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS,** with whom applications (8 copies) including curriculum vitae and the names and addresses of two referees, should be lodged not later than August 8th 1990. Please quote reference number 1537. (4070)A

TRANSVAAL MUSEUM
DIRECTOR

Applications are invited for the post of Director of the Transvaal Museum in view of the impending retirement from management of Dr. Bob Brain.

The Transvaal Museum is a state-subsidised natural history museum of international repute with a strong research tradition in the fields of Mammals, Birds, Lower Vertebrates and Invertebrates, Lepidoptera, Coleoptera, General Entomology, Palaeontology and Archaeozoology. It has an excellent natural history Library, Display and Technical Departments, and a staff of 94.

The Director is the Executive Officer of the Board and is expected to provide creative leadership in curation, research and education. A generous salary and service benefits are provided, details of which are available on application. Requirements are a higher degree in natural science and extensive experience in the work of natural history museums, and proficiency in both official languages.

Applications close on August 15th 1990 for appointment on 1st June 1991 and should be addressed to the **Director, Transvaal Museum, P.O. Box 413, Pretoria.** Tel: (012) 3227632, Fax: (012) 3227939. (W7507)A

THE UNIVERSITY OF LEEDS
Department of Biochemistry and Molecular Biology
CHAIR OF BIOCHEMISTRY

Applications are invited for the established Chair of Biochemistry, which will become available on the retirement of Professor Donald S. Robinson in September 1990. This prestigious Chair will be held in a major new department, formed by the merger of the present separate Departments of Biochemistry and Biophysics. Applicants who have an international scientific reputation in any area of biochemistry or molecular biology will be considered. The salary will be within the non-clinical professorial range.

Further particulars may be obtained from the **Registrar, The University, Leeds LS2 9JT** (tel 0532-333969) quoting reference number 83/102. Applications (2 copies) stating age, giving details of qualifications and experience, naming three referees and providing a statement on how, if successful, the applicant would envisage fulfulling the requirements of the post should reach the Registrar not later than 14 September 1990. Applicants from overseas may apply in the first instance by telex (556473 UNILDS G) or facsimile (0532-336017 or 0532-334123), naming three referees, preferably at least one in the United Kingdom.

The University of Leeds is an equal opportunities employer

(4001)A

TECHNICAL DIRECTOR
up to £50,000

Our client is one of Europe's leading biotechnology companies located in the south-east of England. The company is planning a rapid phase of expansion and, as part of the new reorganisation, is seeking a high calibre scientist and manager to direct all research and technical operations.

The successful candidate will have a first class record in the management of biotechnology disciplines including microbiology, medical chemistry and emzymology. Experience in the organisation and running of a wide range of technical projects (budgets of £2-3 millions per annum) is essential and the candidate must possess excellent man management and communicative skills. There will be a seat on the Board and you will report to the Chief Executive.

This is a unique and challenging position, offering a superb opportunity with a rapidly expanding and successful company.

Please send full career details, listing any companies to whom your application should not be sent, to:

North East Surrey College of Technology

FACULTY OF SCIENCE & TECHNOLOGY

SCHOOL OF APPLIED PHYSIOLOGY

Senior Lecturer in Physiological Measurement/ Medical Physiology

and

Lecturer in Applied Physiology

Applications are invited from suitably qualified persons to join an established and enthusiastic team concerned with the education and training of students across a range of subjects in Physiology on BTEC, Honours Degree and Professional courses. In addition to suitable academic and professional/research qualifications, relevant hospital, industrial or other experience would be a distinct advantage.

For the Senior Lecturer post, the ability to undertake administrative duties related to course and subject development are essential. Research and consultancy are encouraged.

Salary scale:

SENIOR LECTURER:	£16752 – £20217 p.a. plus £384 London Fringe Allowance
LECTURER:	£9243 – £16752 p.a. plus £384 London Fringe Allowance
	Generous relocation expenses in approved cases

Further information about the above posts and application forms can be obtained from the **Vice Principal, NESCOT, Reigate Road, Ewell, Epsom, Surrey KT17 3DS.** Please send a large stamped addressed envelope. (4065)A

SURREY COUNTY COUNCIL

UNIVERSITY OF KUWAIT HEALTH SCIENCE CENTRE

Faculty of Allied Health Sciences & Nursing

Teaching Appointments in Medical Laboratory Technology

Kuwait University seeks motivated individuals who are attracted by the challenge of preparing young professionals to lead one of the world's fastest developing health care systems into the 21st century.

The Faculty of Allied Health Sciences and Nursing offers 4-year University-based B.Sc. programmes, with practical training carried out in local hospitals. Appointees to all posts will participate in both theoretical and practical teaching, and development and management of their respective programmes. The language of instruction is English.

Positions

a) **Chairman:** At the level of Professor with expertise in any of the disciplines taught within the department and strong administrative experience required.

b) **Haematologist:** At the level of Assistant or Associate Professor — clinical laboratory experienced required.

c) **Clinical Chemist:** At the level of Assistant or Associate Professor.

d) **Histologist:** At the level of Assistant or Associate Professor — experience in both microscopic anatomy and histotechnology required.

Requirements for appointment

1. Professors, Associate Professors and Assistant Professors

   All applicants must possess a Ph.D., or equivalent qualification, in their speciality. Professors must have 14 years experience since their B.Sc., including 8 years since their Ph.D., and have served at least 4 years as an Associate Professor. Associate Professors must have at least 9 years experience since their B.Sc., including 4 years since their Ph.D., and have served at least 4 years as an Assistant Professor. Candidates for Professor and Associate Professor should have a substantial record of research publications in journals of international repute.

Benefits

1. Totals monthly salary within the following scales:

Professor	KD 1070-1230	(8 annual increments)
Associate Professor	KD 875-1035	(8 annual increments)
Assistant Professor	KD 680-840	(8 annual increments)

   1KD = US $ 3.3, UK £ 2.0 approx.

   In addition, for teaching staff who have an active part in the Ministry of Public Health programme, there is a monthly supplement (Lecturer, KD.100; Senior Lecturer, KD.125; Assistant Professor, KD.200; Associate Professor, KD.250; Professor, KD.300) for 10 months a year paid by the Ministry. There is no income tax in Kuwait, and currency is transferable without restriction.

2. An attractive package of associated benefits includes free furnished accommodation, 60 days paid summer leave and 10 days mid-year break for teaching staff, round-trip air tickets, end-of-service gratuity, free medical care in Kuwait government hospital. For Professors, Associate Professors and Assistant Professors furnished accommodation will be provided with water and electricity against deduction of fixed sum from the Social Allowance.

3. Professors, Associate and Assistant Professors also receive a generous baggage and freight allowance, and education allowances for up to 3 children, and may attend one approved conference per year.

Applications

Applications in duplicate, including full curriculum vitae, personal details, comprehensive publication list, 2 recent passport photographs and the names and addresses of 3 referees, should be sent to:

The Dean
Faculty of Allied Health Sciences and Nursing,
Kuwait University Health Science Centre,
P.O. Box 31470,
90805 Sulaibikhat,
Kuwait.

To arrive no later than 30th November, 1990.

Applications for appointments starting later than September 1991 will be considered at anytime.

APPLICATIONS AND CONDITIONS OF SERVICE MAY BE OBTAINED FROM:

EMBASSY OF THE STATE OF KUWAIT
CULTURAL AFFAIRS OFFICE
46, QUEEN'S GATE
LONDON, SW7 5HR

(W7512)A

UNIVERSITY OF EDINBURGH

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the following post:

LECTURER (temporary)

The post is tenable from 1st January 1991 (or as soon as possible from thereafter) to 31st December 1993. Candidates should be active in any aspect of biochemistry, cell biology or molecular biology. The Department of Biochemistry has a rapidly growing research profile and has teaching responsibilities in the Faculties of Medicine and Science. Strong encouragement will be given to an appointee wishing to develop a research programme either independently, or in collaboration with existing groups, and to attract external funding.

Those wishing to make informal enquiries are invited to telephone the Acting Head of Deparment, Dr David Apps (031-667 1011 ext 2336), and further particulars of the appointment may be obtained from the Personnel Office, 63 South Bridge, Edinburgh EH1 1LS.

Salary will be on the Lecturer scale AT2A (currently £12,086-£16,755 per annum). USS Superannuation.

Applications (5 copies) should include the names and addresses of two referees, and should be lodged with the **Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh, 63 South Bridge, Edinburgh EH1 1LS** not later than August 15th 1990. *Please quote reference no. 1536.*

(4064)A

RE-ADVERTISEMENT

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

DEPARTMENT OF IMMUNOLOGY

Research Officer

Research Officer required for project to investigate minimal disease in acute leukaemia using polymerase chain reaction technology. Previous experience with recombinant DNA technology, including PCR, is required. In particular, applicants who have been working with T cell receptor genes and have a broad knowledge of molecular biology and an understanding of lymphocyte development are invited to apply. The position is for three years supported by Leukaemia Research Fund on Research Scale 1A plus £1,767 London Allowance.

Job description available from the **School Office, RFHSM, Rowland Hill Street, London NW3 2PF (tel: 071-794 0500 ext 4262)** to which applications (2 copies of curriculum vitae plus names and addresses of two referees) should be sent by 20 July 1990. Please quote ref: IMM/RO/114.

(4057)A

POSTDOCTORAL POSITION

In virology available immediately to study the molecular biology of RNA-RNA recombination in plant mRNA viruses in NIH-funded project. Experience with molecular techniques desirable. Two/three years available. Salary commensurate with experience.

Send curriculum vitae and three references to: **Dr. J. J. Bujarski, Northern Illinois University, Department of Biology/PMBC, DeKalb, IL 60115. Telephone: 815-753-0601.**

(NW5511)A

ASSOCIATE RESEARCH SCIENTIST

Non-tenure track position in cell physiology and biochemical studies of endothelial biology. Experience required in hybridoma antibody production, protein chemistry and cell culture. Applicant should have experience in studies of endothelial function and a doctoral degree.

Applications with full CV should be sent to **Dr. David Stern, Department of Physiology and Cellular Biophysics, College of Physicians and Surgeons, Columbia University, 630 West 168th Street, New York, NY 10032.** *Columbia University is an Affirmative Action/Equal Opportunity Employer.*

(NW5509)A

POST-DOCTORAL AND PRE-DOCTORAL RESEARCH ASSISTANTS

National Institute for Medical Research and National Heart & Lung Institute

Applications are invited for Postdoctoral and Pre-doctoral positions to work with Drs. F. Anthony Lai and Alan Williams on a 3 year, British Heart Foundation funded project designed to study the structure-function relationships of the calcium release channel (ryanodine receptor) of cardiac muscle sarcoplasmic reticulum.

The Post-doctoral assistant will be based with Dr. Lai at the National Institute for Medical Research, Mill Hill. Experience in molecular biology and biochemical techniques would be an advantage. Ref No: BHF/111.

The Pre-doctoral assistant will be based with Dr. Williams at the National Heart & Lung Institute in central London and will undertake the functional aspects of the project. Experience or interests in single channel techniques or membrane biochemistry would be an advantage and a suitably qualified person would be encouraged to register for a higher degree. Ref No BNF/112.

Applications for both posts should be sent by 20th July 1990, to **Amanda Wilson, Personnel Manager, National Heart & Lung Institute, Dovehouse St., London, SW3 6LY. Tel 071-351 8176. FAX: 071-376 3442.**

Further Information on the project may be obtained from Dr. Alan Williams on 071-352 81221 ext. 3308. (4090)A

THE ERNA AND JAKOB MICHAEL VISITING PROFESSORSHIPS 1991/92

THE JOSEPH MEYERHOFF VISITING PROFESSORSHIPS 1991/92

THE ROSIE AND MAX VARON VISITING PROFESSORSHIPS 1991/92

The Weizmann Institute of Science, Rehovot, Israel offers a limited number of Visiting Professorships in the Natural and Exact Sciences.

The Visiting Professorships are intended for candidates already holding the rank of Full Professor or equivalent and will be for a duration of two months to one year.

Deadline for submittance of completed applications is: November 30, 1990.

For further information or application forms, please contact: **The Academic Secretary, The Weizmann Institute of Science, Rehovot 76100, ISRAEL. (Telex — 972-8-381300, facsimile — 972-8-471667, Bitnet—RSMARJOR@WEIZMANN).** (W7513)A

UCB — PHARMA RESEARCH CENTRE
Brussels, Belgium

CLINICAL NEURO-SCIENTIST

UCB-Pharma is a pharmaceutical company within the UCB Group engaged in long-term research with the aim of developing effective agents for the treatment of disorders of the CNS, the Cardiovascular and the Immune System.

Our Research Centre, located near Brussels, Belgium, is looking for a highly skilled, motivated and creative clinical scientist to join its CNS-Therapeutic research and development unit. The key issue will be the integration of animal models of CNS diseases and clinical validation of such models to discover and develop new treatments of CNS disorders.

The person appointed will be a neuropsychiatrist, neurologist or equivalent with both clinical experience and a laboratory background. He or she will be able to demonstrate productivity in the CNS area by means of publications, etc.

The person appointed will be based at UCB's modern research campus in Braine-l'Alleud, just south of Brussels, so a knowledge of French would be useful, though not essential. Personal qualities should include scientific drive and rigour, flexibility, a creative outlook, and the tact and diplomacy to deal with people at all levels.

This opportunity to develop a whole new range of research processes is of course a senior appointment, and offers excellent remuneration and benefits, together with pleasant working surroundings and generous relocation expenses.

If you feel you can meet this challenge and would like more information, please contact, in the first instance, **Dr Colin WILSHER, UCB R&D UNIT, C/O UCB (PHARMA) Ltd., Star House, 69 Clarendon Road, Watford, Herts WD1 1DJ** — Telephone: 0923 248011. (W7518)A

The **European Southern Observatory (ESO)** is an intergovernmental organization responsible for astronomical research in the southern hemisphere. The eight member states of the ESO are Belgium, Denmark, France, Italy, the Netherlands, the Federal Republic of Germany, Sweden and Switzerland.

The ESO occupies a leading position in the world scientific community as the first European astronomical centre. Its research is of use for a wide range of sciences as well as industry.

EUROPEAN SOUTHERN OBSERVATORY

is looking for an (m/f)

ASTRONOMER/DATA ARCHIVIST (ref. ESD307)

to start work as soon as possible in the Image Processing Group of the Science Division at the ESO Headquarters in Garching near Munich, Federal Republic of Germany.

Assignment: This position will entail maintenance and further development of an archiving system mainly for data acquired with the ESO telescopes in Chile. This includes maintenance and improvement of methods for storing original data, for searching and retrieving these data, and managing the access of users to the archive, general management of data bases relating to the Science Division using a Sybase Date Base Managing System on UNIX based computers as well as development and maintenance of interfaces between such systems and the MIDAS image processing system.

Experience and knowledge: University degree in astronomy, physics, mathematics, computer science or equivalent. Familiarity with data base management systems, computer operations and high level programming languages like C is required, as is experience in the development of science application software. A good background in astronomy and experience in the handling of astronomical data are desirable. Working experience with UNIX would be an advantage. A good working knowledge of English is indispensable: some knowledge of French or German would be an advantage.

Remuneration: The remuneration for this post is commensurate with the background, experience and family status of the candidate. The basic monthly salary (tax-free) will be between DM 4,994 and DM 7,413 to which may be added a non-resident allowance of either 9% (single) or 12% (head of family) as well as some other allowances.

Although preference will be given to nationals of the ESO member states, no nationality is a priori excluded.

Applications, indicating the reference number, should be submitted before August 15, 1990 to

Personnel Administration and
General Services,
European Southern Observatory,
Karl-Schwarzschild-Straße 2,
D-8046 GARCHING b. München,
Federal Republic of Germany

RESEARCH ASSOCIATE

We are seeking an individual with research experience in mechanisms of human airway inflammation. The position provides a unique opportunity for a creative scientist to work independently and in collaboration with a multidisciplinary team of University of North Carolina and U.S. Environmental Protection Agency scientists active in the area of pulmonary cell and molecular biology. The successful candidate should have at least 2 years of postdoctoral training in biological and biochemical approaches to study mediators including neurogenic substances and cytokines involved in the inflammatory/allergic response. Competitive salary and fringe benefits commensurate with education and experience. Interested applicants should send curriculum vitae, a statement of research interests and goals, and the names of three references to: **Dr. Hillel Koren, Center for Environmental Medicine and Lung Biology, University of North Carolina School of Medicine, CB #7030, Medical Research Building C, Chapel Hill, NC 27599.** *Affirmative Action/Equal Opportunity Employer.* (NW5510)A

UNIVERSITY OF CAMBRIDGE
SCHOOL OF CLINICAL MEDICINE
DEPARTMENT OF MEDICINE (NEUROLOGY)

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for the position of Post-Doctoral Research Assistant to work on calcium imaging and membrane physiology of glia. The work will be carried out jointly in the Department of Medicine (Neurology) on the Addenbrooke's Hospital Site with Alastair Compston and the Neurosciences Research Group of Smith Kline Beecham in Harlow with Chris Benham. Technical experience in single cell electrophysiology and/or cell culture would be an advantage.

The post is funded by Smith Kline Beecham and is available from 1 July 1990 for three years. The University of Cambridge conditions of service will apply and the salary is in the range £10,458-£15,372 (under review) depending on age and experience.

Applications including curriculum vitae and the names of at least two referees should be submitted to Mr. K. G. Smith by 31 July 1990. Further details may be obtained from **Professor Alastair Compston, University of Cambridge School of Clinical Medicine, Addenbrooke's Hospital, Cambridge CB2 2SP (tel: 0223-217091).**

The University follows an equal opportunities policy. (4074)A

UNIVERSITY OF ABERDEEN
SCHOOL OF BIOMEDICAL SCIENCES

RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant to work on a project concerned with cell lineage in developing mouse muscle. This will involve the use of a replication deficient retrovirus to introduce a marker gene into cells. This will enable the identification and subsequent fate of cell populations to be followed.

Applications should either have a Ph.D. or an Honours Degree in a relevant subject. A knowledge of histology and electron microscopy would be advantageous, but is not essential as training will be given. The post is tenable for one year commencing September 1990. Salary placement on the Scale £10,458-£12,381 per annum depending on qualifications and experience.

Informal enquiries to Dr. Peter Wigmore (0224 273095). Further particulars from the Personnel Office (0224 273500). Applications by letter and CV (two copies) including the names of three referees to the **Personnel Office, University of Aberdeen, Regent Walk, Aberdeen AB9 1FX** by 27th July 1990 quoting reference LG/029. POSTDOCTORAL POSITION

Signal Transduction Mechanisms in Leukaemia Cells

Following the establishment of a new laboratory in the Department of Immunology by Dr. Denis Alexander, a postdoctoral position funded by the Leukaemia Research Fund is available for research on mechanisms involved in transducing activation signals from cell-surface receptors in human leukaemia cells. The research will have an emphasis on the role of kinases and phosphates (reviewed in Immunology Today 10, 200-205, 1989) and would suit someone with a background in cell biology/enzymology/immunochemistry. The position is available as from 1st August, but candidates wishing to start at any time up to 1st November 1990 will be considered. The position is funded for 3 years in the first instance and will be made at an HSO or SSO level (salary range £10,678-£15,504) depending on qualifications and experience, with a non-contributory superannuation scheme and 25 days leave.

The Institute is situated in pleasant countryside just outside Cambridge and provides an excellent environment for academic research.

Applications containing a full curriculum vitae and the names and addresses of three referees should be sent to the Personnel Office, AFRC Institute of Animal Physiology and Genetics Research, Babraham, Cambridge CB2 4AT, as soon as possible, quoting Ref. DA/ST. Informal enquiries by telephone to Dr. Denis Alexander (Tel. 0223 832312 Ext. 554). (4076)A

Still first with the best in science

UNIVERSITY OF BRISTOL

Departments of Microbiology & Pathology

Research Assistant

pplications are invited for the post of post-doctoral Research ssistant funded by a project grant from the Wellcome Trust, hich as 2½ years to run and is to investigate herpes simplex rus-induced demyelinating disease.

he successful applicant will join a multi-disciplinary programme hich is well-funded in this field. Experience in molecular ology, immunology, histology .or cell-culture techniques dvantageous although training available in all of these areas.

alary within the range £10,458-£16,665 (Research 1A under revi- on from 1.5.90) according to age, qualifications and experience.

urther information may be obtained from Dr S Love (0272 701212 xt. 2382), Dr T Hill (0272 303030 ext. 4908) or Dr N Maitland (0272 03454).

or further details telephone 303136 (ansaphone after 5 p.m.) or rite to the **Personnel Office, University of Bristol, Senate House, ristol BS8 1TH**, quoting reference number 294.

n Equal Opportunities Employer. (4062)A

LIVERPOOL HEALTH AUTHORITY

Department of Chemical Pathology

INICAL BIOCHEMISTS — 2 POSTS

1) Grade B salary £15,999 – £17,304
2) Grade B salary £12,644 – £13,676

quired to work in the above artment recently affiliated to University of Liverpool.

he department is part of a jor teaching hospital, covers a nprehensive analytical service has its own 4-bedded meta- ic unit and associated clinics.

ou will be expected to have vious clinical laboratory erience and to contribute to utine and development work he department. Post (1) development of interests associated with nutrition and metabolism, cell culture and bio assay or molecular biology associated procedures; post (2) in the trace and toxic metal section.

Qualifications required are a first or second class honours degree in biochemistry or related subject and preferably a higher degree PhD and/or MCB/ MRCPath. Opportunities will be available to study for a professional qualification if required.

Further information is available from Professor A. Shenkin or Dr. N.B. Roberts, telephone number 051-709 0141 ext 2823/1.

Application forms can be obtained from the Personnel Department, Royal Liverpool Hospital, Prescot Street, Liverpool, tel no. 051-709 0141 ext 2253. Closing date 19th July 1990.

(4072)A

ROYAL POSTGRADUATE MEDICAL SCHOOL

(University of London)

DIVISION OF MOLECULAR ENDOCRINOLOGY & METABOLISM

GRADUATE RESEARCH ASSISTANT

Applications are invited from graduates to join a dynamic team working in the rapidly expanding field of cell regulatory mechanisms in both physiological states. The current programme centres on the hypothalamic pituitary axis and the islets of Langerhans. We have a policy of encouraging all suitable candidates to register for a PhD.

Techniques used in the Unit include radioimmunoassay, receptor binding assays, reverse haemolytic plaque assays, cell culture, nortern blotting and fluorescence activated cell sorting. Experience with any of these techniques would be helpful but we expect to provide full training as required. Applicants should have an interest ir. biology and a reasonable class degree, preferably in a biological subject.

Salary will be in the range £7,594 – £10,903 plus £1,580 London Allowance. Please send full CV with names and telephone numbers of two referees to the **Personnel Office, Royal Postgraduate Medical School, Du Cane Road, London W12 0NN** quoting ref: AMV1. Informal visits to the laboratories can be arranged by telephoning Dr M A Ghatei on 081-740 3044.

Closing Date: 19 July 1990. (4067)A

MEDICAL RESEARCH COUNCIL

COLLABORATIVE CENTRE

The MRC Collaborative Centre was founded in 1986 to act as a link between MRC basic research units and industry. At the Collaborative Centre, commercially-orientated research projects are carried out with scientific support from within the MRC and financial support from industry. Located adjacent to the National Institute for Medical Research in the pleasant semi-rural surroundings of Mill Hill, the Centre has been recently refurbished and is equipped to a high standard. In addition, staff at the Centre have access to a range of computing, library, technical, and recreational facilities at the NIMR.

The **Antibody Engineering Group** at the Collaborative Centre carries out projects focusing on the cloning and manipulation of immunoglobulin genes to create novel diagnostic and therapeutic agents. We currently have two new openings. Appointments will be for two years in the first instance with the possibility for extension.

SCIENTIFIC OFFICER

We are seeking a scientist with experience in recombinant DNA technology to work on the cloning and expression of immunoglobulin genes. The salary will be on the Civil Service Scientific Officer scale ranging from £10,646 to £13,738 per annum (inclusive of London Weighting). An optional MRC pension scheme is available with a 4.5% salary supplement. Applicants should possess a first degree, BTEC, or equivalent qualification. Please telephone for an application form, quoting reference number CC/AE SO2, on 081 959-3666 x 2270, or write to **Ms. Frances Griffiths, Personnel Officer, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA.**

POSTDOCTORAL SCIENTIST

We are seeking a molecular biologist with practical experience in recombinant DNA technology and with an interest, and preferably some experience, in protein engineering and/or molecular immunology. The salary will be in the range £12,225-£22,229 per annum (inclusive of London Weighting). An optional MRC pension is available. Applicants should send a curriculum vitae and the names of two referees to **Mr. C. R. Russell, Administrative Manager** at the above address, quoting reference number CC/AE PD2.

Informal enquiries for either of the positions may be made to Dr. M. M. Bendig on 081 906-3811. Applications are requested as soon as possible.

The MRC is an Equal Opportunity Employer. (4113)A

STUDENTSHIPS

UNIVERSITY OF ABERDEEN

SCHOOL OF BIOMEDICAL SCIENCES

3 YEAR ANATOMICAL SOCIETY STUDENTSHIP

Applications are invited for a 3 year studentship to work on cell lineage in developing mouse muscle. This will involve the use of a replication deficient retrovirus to introduce a marker gene into cells. This will enable identification and subsequent fate of cell populations to be followed.

It would be an advantage for candidates to have a knowledge of histology and electron microscopy although training will be given. Applicants should have at least an Upper Second Class Degree in a relevant subject and must be British or Irish subjects.

Applications including a full CV and the names of two referees, or informal enquiries, should be made to Dr Peter Wigmore, School of Biomedical Sciences, Division of Anatomy, Marischal College, Aberdeen AB9 1AS (tel. 0224 273095). (4111)F

Research Studentship

A Studentship is available for work on *cloning, structural determination and localisation of neurotransmitter and neuropeptide receptors in a variety of species.* Further information is available from Dr Karin Eidne (tel: 031 229 2575).

Applications, including the names of two referees, to **Ena McKay, MRC Reproductive Biology Unit, Centre for Reproductive Biology, 37 Chalmers Street, Edinburgh, EH3 9EW.** (4112)F

DEPARTMENTS OF BIOCHEMISTRY AND MEDICINE
MUSCLE RESEARCH CENTRE

POSTGRADUATE STUDENTSHIP

Supported by the Muscular Dystrophy Group of Great Britain and Northern Ireland and leading to the degree of Ph.D. The project, which carries a stipend of £6,000 p.a. + fees + travel expenses, will examine the genomic lesions and genetics of McArdle's disease, a heritable deficiency in muscle glycogen phosphorylase that leads to severe disruption of muscle energy supply. The student will be based in the Department of Biochemistry (Dr R. J. Beynon) but will also work closely with Professor R. H. T. Edwards in the Department of Medicine.

For further details contact Dr Beynon on 051-794 4359 by whom applications should be received as soon as possible at the address below.

DEPARTMENT OF GENETICS AND MICROBIOLOGY
SCHOOL OF LIFE SCIENCES

NERC-CASE PH.D. STUDENTSHIP

Tenable for three years from 1 October, 1990.

To develop molecular methods for monitoring survival and gene transfer in recombinant pseudomonads released into aquatic environments. The project will be supervised jointly by Dr J. R. Saunders (Liverpool) and Dr R. W. Pickup of the Institute of Freshwater Ecology, Windermere, Cumbria where the student will spend 3-6 months.

Applicants should have or expect to obtain a first or second class honours degree and have some knowledge of molecular genetic and/or immunological methods.

Enquiries and applications together with the names and addresses of two referees should be received as soon as possible by Dr J. R. Saunders, Department of Genetics and Microbiology, at the address below. (Tel: 051-794 4416).

PH.D. STUDENTSHIPS

Available for the following projects:

Heavy metal resistance genes in bacteria from polluted soil. Professor D. A. Ritchie, Dr P. Strike and Professor S. T. Williams (3624).

NERC/CASE Award with Institute of Freshwater Ecology, Windermere, on Molecular approaches to monitoring the fate and activity of recombinant pseudomonads in soil and aquatic sediments. Dr J. R. Saunders and Dr R. W. Pickup (4416).

Applications are invited from students who either hold, or expect to obtain, an Upper Second class Honours degree in a relevant subject.

Further information can be obtained by ringing 051-794 plus the appropriate number in brackets, or in case of difficulty, the Secretary on 051-794 3622.

Applications, together with a cv and the names and addresses of two academic referees, with the title of the preferred project(s) should be addressed to the named supervisor, Department of Genetics and Microbiology, at the address below.

The University, PO Box 147, Liverpool L69 3BX

University of LIVERPOOL

AN EQUAL OPPORTUNITY EMPLOYER (4094)F

THE UNIVERSITY OF BIRMINGHAM/
ICI PHARMACEUTICALS

MRC COLLABORATIVE PH.D STUDENTSHIP

THE WHITE CELL RESPONSE IN ISCHAEMIA

Department of Haematology, The Medical School

A postgraduate studentship is available, based in the Medical School, but with significant time spent in the ICI Pharmaceuticals Bioscience Laboratory, Alderley Park, Macclesfield. The project is a study of changes in the flow behaviour of white cells caused by ischaemia, and possible therapeutic interventions. The work is inter-disciplinary and those with backgrounds in the biological or physical sciences are invited to apply. A supplementation of £1200 to the standard stipend will be paid.

Further information and application forms (returnable by 2 August 1990) from **Dr G Nash, Department of Haematology, The Medical School, Birmingham B15 2TT. Tel: 021 414 4040.** (4097)F

Research Studentships in Biochemistry

DEPARTMENT OF BIOCHEMISTRY
UNIVERSITY OF DUNDEE

A number of CASE (denoted ¶) and earmarked Research Studentships are available for the following projects:

Dr. B Spruce & *Prof. D Glover*	The intracellular trafficking and biological role of a mammalian neuropeptide procursor within neuro-endocrine and glial cells ¶
Dr. D Boxer	Regulation and biosynthesis of metalloenzymes in *E. co* Structural analysis of nickel-binding proteins in *E. coli* ¶
Dr. S W Homans	Three-dimensional structure of biologically active oligosaccharides by NMR and computational methods
Prof. D M J Lilley	Nucleic acid structure and DNA-protein interactions
Dr. M J R Stark	Development of molecular genetics in the yeast *Pichia pastoris* ¶

These places will all be supplemented in the first year with a bursary of £250 (£500 for candidates with a First Class Honours degree). The Department is one of the most successful and highly rated in the UK for biochemistry research and is very well equipped and funded. In addition to the outstanding research facilities and working environment, Dundee boasts excellent access to outdoor recreational facilities and accommodation/living expenses are among the lowest in Britain.

Applications, including a full curriculum vitae and the names and addresses of two referees should be sent immediately to **Dr M J R Stark, Department of Biochemistry, The University, Dundee DD1 4HN (tel. 0382-23181 ext. 4250)**. Prospective applicants are strongly encouraged to phone first. Candidates should have (or expect to have) at least an upper second class honours degree and be normally resident in the U.K.

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF PHARMACOLOGY

CASE STUDENTSHIP IN COLLABORATION WITH ICI PHARMACEUTICALS

FOR A PROJECT ON "ENDOTHELIUM-DERIVED VASOACTIVE FACTORS, LIPOPROTEINS AND ATHEROSCLEROSIS

Applications are invited for a CASE studentship under the supervision of Dr M. Jacobs, to study the role of lipoproteins in the alteration of vascular responses by atherosclerosis. Applicants should hold a first or upper second class honours degree in Pharmacology or related subjects and wish to undertake research for a PhD in Pharmacology.

The studentship is tenable for 3 years starting October 1990. Informal enquiries should be made to **Dr M. Jacobs, Department of Pharmacology, RFHSM, Rowland Hill Street, London NW3 2PF (tel: 071-794-0500 ext 4300)** to whom applications, including curriculum vitae and the names and addresses of two referees, should be sent. (4068)F

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF BIOCHEMISTRY

SERC PhD STUDENTSHIP

Applications are invited for a studentship to work with Dr S. J. Perkins (Biochemistry) and Dr V. C. Emery and Dr J. E. Grundy (Virology) for biochemical and structural studies of viral proteins in cytomegalovirus and papillomavirus using synthetic peptides and/or recombinant DNA techniques and sequence analyses. Excellent facilities in new laboratories are available.

Applicants should have a 1 or 2-i in Biochemistry or other relevant subject. The award will be supplemented by £500 p.a., and there will be opportunities for part-time demonstrating.

Applications, including a curriculum vitae and names of two academic referees, should be sent as soon as possible to **Dr V. C. Emery (071-794-0500 ext 3109), Department of Virology, RFHSM, Rowland Hill Street, London NW3 2PF,** from whom further details can be obtained. (4059)F

DEPARTMENT OF MICROBIOLOGY
UNIVERSITY OF SURREY
BIOTECHNOLOGY DIRECTORATE
PhD STUDENTSHIPS
(quota and CASE)

vo studentships are available for three years from October 1990:

Molecular studies on cellular physiology.

e objective is to study the production of ammonia by animal cells in lture. The project will involve the expression of cloned genes in ammalian cells and studies on the effect of this expression on llular physiology, particularly with regard to the production and ilisation of ammonia.

e studentship will provide research training in aspects of molecular ology, cell physiology and the large scale culture of cells in bioreactrs.

r further infomation contact Prof. R.E. Spier (0483 571281 ext. 2662) Dr. P.G. Sanders (0483 571281 ext. 2665).

Factors affecting secondary metabolite production in bioreactors.

e objective is to quantify the influence of physical, physiological d molecular factors on antibiotic yield and gain some insight into e reasons why batch to batch variability exists between successive oreactors runs. This is a CASE studentship with Shell UK Ltd.

esearch training will be provided in fermentation physiology, electon microscopy and biochemical/molecular techniques.

r further information contact Dr. M.E. Bushell (0483 509277).

epartment of Microbiology, University of Surrey, GUILDFORD, urrey, GU2 5XH.

pplications, including CV and the names of two referees should be ent to Dr. P.G. Sanders or Dr. Bushell ASAP but no later than 20th uly 1990. (4098)F

DIVISION OF PHYSIOLOGY
UNIVERSITY OF ABERDEEN

Applications are invited for a University funded Ph.D. studentship in the Division of Physiology starting October 1990. The project will be supervised by Stephen Davies and will involve the use of electro-physiological techniques to study the mechanisms of synaptic transmission and synaptic plasticity in brain slice preparations. The stipend will be at the same level as Research Council studentships and candidates should hold, or expect to hold, an upper second or first class degree. Informal enquiries may be made by telephone on (0224) 273016/273010, or in writing to **Dr. S. N. Davies, Division of Physiology, School of Biomedical Sciences, Marischal College, Aberdeen, AB9 1AS**. Replies as soon as possible please. (4108)F

UNIVERSITY OF LONDON
ROYAL HOLLOWAY AND
BEDFORD NEW COLLEGE

PETROLEUM SCIENCE AND
TECHNOLOGY INSTITUTE
EDINBURGH

PhD Research Studentship on FAULT SEALS

The research objective is to identify common processes which control ault seals and determine the conditioins at which they operate. This will have direct bearing on subsurface fluid migration. The student will undertake extensive field work in the Western Alps and Britain, and examine cores from North Sea wells. A wide range of analytical echniques will be used to investigate deformation mechanisms and chemical processes in fault zones, using XRD, XRF, cathodoluminescence, fluid inclusions, and stable and radiogenic isotopes. The student will also gain experience working in oil company offices examining seismic data, and electric logs.

Petroleum Science and Technology Institute offer a stipend of c. £5,550 per annum and excellent research support.

Please send CV and names of two academic referees to **Dr. Ian Davison, Dept. of Geology, Royal Holloway and Bedford New College, Egham, Surrey, TW20 0EX**. For informal enquiries Tel. 0784 43615. (4095)F

THE UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF OPHTHALMOLOGY
RESEARCH STUDENTSHIP
Birmingham Hospital's Endowment Fund
Infant Visual Development:
"The Design and Use of Acuity Cards"

Applications are invited from graduates in Psychology, Physiology, Optometry or other relevant discipline.

FELLOWSHIPS

University of Newcastle upon Tyne

Postdoctoral University Fellowship

Departments of Obstetrics/Physiological Sciences

A Research Fellowship, funded by the University of Newcastle upon Tyne, is available for one year to investigate the cellular physiology of human pregnant myometrium. The project involves the measurement of force production and intracellular ion changes by microspectrofluorimetry in isolated tissues. Experience in cellular physiology is requested.

Salary will be within the range £10,458 to £12,381 p.a. on the Grade 1A scale according to qualifications and experience.

Further information can be obtained by writing to, or telephoning **Dr. J.I. Gillespie, Department of Physiological Sciences, The Medical School, Framlington Place, Newcastle upon Tyne NE2 4HH** (Tel. 091-222 7010) with whom applications, with full c.v. and the names and addresses of three referees, should be submitted by 3rd August 1990. (4066)E

University of Cambridge

Postdoctoral Fellowship in Neurobiology

A postdoctoral position will be available from Sept 1st 1990 with Prof M Burrows to study the function of local neurones in controlling the locomotion of an insect. The post, which is funded for 3 years by the Human Frontier Science Program, offers the opportunity to join an active multidisciplinary research group and to participate in collaborations with laboratories in Berlin F.R.G., Hokkaido Japan, and Cal. Tech U.S.A.

Salary typically in the range £11,088-12,879 depending on age and experience.

Please contact, or send applications, including the names of 2 referees to,

Prof. M. Burrows,
Department of Zoology,
Downing Street,
Cambridge CB2 3EJ.

(4096)E

ESO FELLOWSHIPS 1991-1992

The European Southern Observatory (ESO) intends to award up to
post-doctoral fellowships tenable in the ESO Headquarters, located
Garching near Munich.

The main areas of activity are:

- to do research in observational and theoretical astrophysics;
- to carry out a program of development of instrumentation for t
  La Silla telescopes;
- to develop future telescopes involving new technology;
- to provide data reduction facilities for users of the ESO instr
  ments;
- to provide photographic facilities for atlases of the southern sky
- to foster cooperation in astronomy and astrophysics in Europe.

Fellows normally participate in one or more of the above. In additic
there is the possibility of participating in the activities of the Europea
Coordinating Facility of the Space Telescope (ST-ECF) which h
been established at ESO.

Fellows will normally be required to spend up to 25% of their time
supporting activities such as the introduction of users to data reductic
facilities, remote control operations and testing new instrumentation.

Fellowships are to be taken up between January and October 1991.

Most of the scientists in the Centre come from the Member States
ESO, but several are from other countries. The Member States of ES
are: Belgium, Denmark, the Federal Republic of Germany, Franc
Italy, the Netherlands, Sweden, and Switzerland. In addition to reg
lar staff members, the Centre comprises visiting scientists, pos
doctoral fellows, and graduate students.

ESO facilities include the La Silla Observatory in Chile with its eig
telescopes in the range 0.9 to 3.6m, as well as a 1 m Schmidt, the 15
SEST and smaller instruments. In Garching, extensive measurin
image processing and computing facilities are available.

Applicants normally should have a doctorate awarded in rece
years. The basic monthly salary will be not less than DM 4341 to whic
are added 7% for pension purposes and a non-residence allowance
9-12% if applicable. The fellowships are granted for one year, wit
normally a renewal for a second year and occasionally a third yea
Applications should be submitted to ESO not later than 15 Octobe
1990. Applicants will be notified in December 1990. The ESO Fellow
ship Application form should be used. Three letters of recommendation from persons familiar with the scientific work of the applicant should be sent to ESO directly. These letters should reach ESO not later than 15 October 1990.

Enquiries, requests for application forms and applications should be addressed to:

European Southern Observatory
Fellowship Program
Karl-Schwarzschild-Straße 2
D — 8046 GARCHING b. München
Federal Republic of Germany

(W7514)E

EMBO

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

SHORT TERM FELLOWSHIPS in molecular biology

The European Molecular Biology Organization awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in extremely exceptional circumstances. Inquiries should be accompanied by a self-addressed adhesive label.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022. 40, F.R.G. (W6896)E

GRANTS & SCHOLARSHIPS

NATIONAL UNIVERSITY OF SINGAPORE

RESEARCH SCHOLARSHIPS

Research Scholarships are available to outstanding university graduates registered for, or admissible to, master's and doctor's degree programmes by research at the National University of Singapore.

The Scholarships are tenable for one year in the first instance and, subject to satisfactory progress, renewable annually for another two years.

The value of each Scholarship ranges from S$1,000.00 to S$1,500.00 per month (£$1.00 = S$3.11 approximately) and is not subject to income tax; the actual quantum is determined on the candidate's qualifications and experience. No travel allowance is provided.

Research Scholars may be asked to assist in the work of the Departments to which they are attached for not more than six hours a week. They can earn up to S$5,400.00 (gross) per annum at the current rate of remuneration from such departmental work.

The University will assist Research Scholars in obtaining accommodation.

Application forms may be obtained from:

The Registrar
NATIONAL UNIVERSITY
OF SINGAPORE
10 Kent Ridge Crescent
Singapore 0511
Republic of Singapore
Telex: UNISPO RS 33943
Telefax: 7786371

NUS Overseas Office
5 Chesham Street
London SW1, UK

In your request for application forms, please state:-

(a) the field of research you intend to undertake; and
(b) your highest educational qualification.

Applications should be received by the Registrar, National University of Singapore preferably by **31 August 1990.** (W7498)H

AWARDS

MEMORIAL UNIVERSITY OF NEWFOUNDLAND DEPARTMENT OF PHYSICS

NSERC FACULTY AWARDS FOR WOMEN

The Department of Physics at Memorial University of Newfoundland is seeking nominees for the *Women's Faculty Awards* recently instituted by the Natural Sciences and Engineering Research Council of Canada. The terms and conditions of these awards are similar to those for the now discontinued University Research Fellowship (URF) program. It is expected that successful candidates will be appointed at the rank of Assistant Professor as of July 1, 1991. Both experimentalists and theoreticians are encouraged to apply. While the area of Condensed Matter Physics is of special interest, qualified candidates in the areas of Physical Oceanography and Atomic and Molecular Physics will also be given serious consideration. All candidates are required to be Canadian citizens or landed immigrants. Applications should include a curriculum vitae with a list of publications and a selection of representative reprints, a research proposal, and the names of at least three referees. Correspondence should be directed as below with a deadline of September 1, 1990.

Dr. M. J. Clouter, Head
Department of Physics

British Council International Medical Course

Immunotherapy with monoclonal antibodies

7-13 April 1991, Cambridge

The aim of this course is to demonstrate the way that basic science can lead to the application of monoclonal antibodies in therapy. The programme will consist of lectures and discussions.

Topics to be covered will include: ways of harnessing natural effector mechanisms to permit antibodies to kill target cells; targeting drugs, isotopes and toxins to tumour cells; engineering antibodies using recombinant DNA methods; bispecific antibodies to direct T-cells to tumours; antibodies as immunosuppressants; animal models of transplantation tolerance with monoclonal antibodies; monoclonal antibodies in the treatment of auto-immunity; monoclonal antibodies in bone-marrow transplantation; antibody therapy in lymphoma and leukaemia; avoiding antiglobulin responses.

The Director of Studies will be **Herman Waldmann**, FRS, Kay Kendall Professor of Therapeutic Immunology, University of Cambridge. The Assistant Director will be **Dr Geoffrey Hale**, Senior Research Associate, Cambridge University Department of Pathology.

The course is designed for basic scientists interested in the application of immunological knowledge to therapy; academic rheumathologists; clinical immunologists; academic transplantation physicians/surgeons and tumour immunologists.

There are vacancies for 30 participants.

Course fee: £725; accommodation charge: £200; total fee £925.

The course sessions will take place at Downing College Cambridge where participants will be accommodated in single study-bedrooms. Bathroom facilities will be shared.

Further information and application forms are available from British Council Representatives overseas or from Courses Department, The British Council, 10 Spring Gardens, London SW1A 2BN.

IBC TECHNICAL SERVICES ARE PLEASED TO ANNOUNCE THE FOLLOWING FORTHCOMING CONFERENCES:

(1) **Bioseparations '90**

New Technologies in Upstream and Downstream Processing
27th/28th September 1990, Cambridge, UK
Chaired by Dr C.R. Lowe and Dr. H.A. Chase

(2) **New Horizons in Dermatology**

Recent Breakthroughs and Likely Developments in the 90's
1st/2nd October 1990, London
Chaired by Professor M Greaves and Professor R Marks

(3) **New Developments in Free Radical Research**

15th/16th October 1990, London
Chaired by Professor T. Slater and Professor H.S. Jacob

(4) **Advances in Inflammation Research**

The Impact of New Developments
31st October/1st November 1990, London

(5) **Biotechnology in the Food Industry**

New Applications and Novel Approaches
26th/27th November 1990

(6) **Monoclonal Antibodies for Clinical Use**

28th/29th November 1990, London

(7) **Potassium Channels '90**

Structure, Modulation and Clinical Exploitation
6th/7th December 1990, London
Chaired by Professor A Weston

For a full conference programme on any of the above events, either telephone Renata Duke in London on 071-236 4080, fax on 071-489 0849 or write to her at **IBC Technical Services, Bath House, 56 Holborn Viaduct, London EC1A 2EX.** (4079)C

SEMINARS & SYMPOSIA

The Zoological Society of London

announces a symposium

BIOTECHNOLOGY AND THE CONSERVATION OF GENETIC DIVERSITY

SEPTEMBER 4-5th, 1990, LONDON ZOO, REGENT'S PARK

Topics and Speakers include:

Tuesday 4 September

Developments in artificial insemination and semen freezing in exotic species (W. J. Holt, London: P. Garland, Orana Park, New Zealand; D. Wildt, Washington D.C.)

Preservation and transfer of eggs and embryos (D. Whittingham, London; B. L. Dresser, Cincinnati; G. J. Morris, Cambridge)

Monitoring and managing fertility *in vivo* and *in vitro* (J. K. Hodges, Gottingen; H. D. M. Moore, London).

Wednesday 5 September

Genetic challenges to long-term population management (A. Schreiber, Heidelberg; E. A. Oakenfull, Oxford)

The role of DNA technologies (D. T. Parkin, Nottingham; W. Amos, Cambridge; J. Avise, Georgia; O. A. Ryder, San Diego)

ntegrating technologies into breeding programmes (J. Ballou, Washington D.C.; G. M. Mace, London; G. Lucas, Kew Gardens; R. Frankham, Macquarie University, Australia)

For further information contact; **Miss Unity McDonnell, Zoological Society of London, Regent's Park, London NW1 4RY. Tel. 071-722-3333** (4104)M

SPECIAL ANNOUNCEMENTS

Alternative Technologic for Sewage

TREATMENT OF VERY LARGE CITIES

The São Paulo State Secretary of Environment is looking for applications from Institutions, scientists or technological groups engaged in projects related with **new or alternative sewage treatment processes to be applied in large cities** (more than 5 million population). Priorities for modular, compact or local treatment processes projects will be taken in account. Applications including c/v and financial conditions should be mailed to:

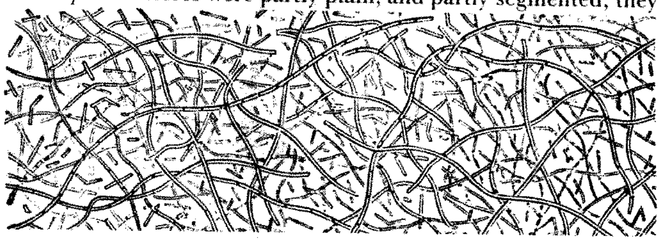
120 YEARS AGO

A FLASK containing a filtered infusion of turnip *in vacuo*, which had been hermetically sealed only *five* days previously, after the fluid had been boiled, was opened on December 15, 1869. On the second day after the flask had been sealed, the previously clear solution began to exhibit a cloudy appearance. The next day a reticulated scum was seen on the surface of the fluid, which gradually became more manifest on the two following days. When the neck of the flask was opened, its contents were found to emit a most fœtid, sickly odour. Microscopical examination revealed a very large number of bacteria and vibrionic-looking rods, some straight and others bent, some motionless and others exhibiting languid movements. These, mixed up with a thickly interlaced network of *Leptothrix* filaments, constituted the reticulated pellicle which was seen on the surface. The *Leptothrix* fibres were partly plain, and partly segmented; they had a precisely similar appearance to the vibrionic-looking filaments, with which in thickness they also closely agreed. The long filaments seemed, in fact, to be only developed forms of the shorter rod-like filaments. A large nucleated ovoid cell was also seen, $^1/_{1428}''$ in its longest diameter, as well as a smaller vesicle, enclosing a rod-like body.



Bacteria, *Vibrios*, and *Leptothrix* filaments, met with in a Turnip-infusion which had been only five days *in vacuo*.

"Facts and reasonings concerning the heterogenous evolution of living things", H. Charlton Bastian.

DEATH has been busy lately among the more eminent members of the medical profession. We have this week to record the decease of Sir James Clark, Bart., M.D., F.R.S., chief physician to Her Majesty, which took place on the 29th ult., in the 82nd year of his age. Sir James had held the appointment of physician to several members of the Royal Family, was the author of several works on climate and on consumption, and was a member of the Senate of the University of London. He attended the poet, John Keats, during his last illness at Rome in 1821.
From *Nature* July 7, 1870.

100 YEARS AGO

ACCORDING to the *Ceylon Observer*, Mr. A. T. W. Marambe, of Kandy, the translator of "Gulliver's Travels" and the author of "A practical Synopsis of Ceylon History," has in preparation a little work on the Veddah language. Many have attempted this task before, but without success. Besides Veddah songs, a description of habits and customs, &c., the book will have a completer list of words than has hitherto appeared.

THE Norwegian Storthing, by 73 votes against 39, has voted a grant of 200,000 kroner for Dr. Nansen's North Pole Expedition.

THE third International Shorthand Congress will be held at Munich from August 7 to 17. The centenary of F. X. Gabelsberger, the originator of modern German shorthand, will be celebrated by those who attend the meetings, and a bronze statue of him will be unveiled.
From *Nature* July 3, 1890.

50 YEARS AGO

GENERAL de Gaulle, leader of the French Volunteer Legion, ha appointed M. André Labarthe director-general of all French se vices connected with armaments and scientific research in Grea Britain. M. Labarthe, who is thirty-eight years of age, has appeale to French engineers, men of science, and industrial workers to joi the already large number of their colleagues who have enlisted a civilian workers in the Legion.

AN instructive address on television given at Buenos Aires last yea by Mr. W. E. Tremain, chairman of the Argentine Centre of th Institution of Electrical Engineers, is published in the May issue o the *Journal of the Institution of Electrical Engineers*. Mr. Tremain begin by saying that the more we study recent developments in television the more we are forced to realize that high-definition television i one of the outstanding scientific and engineering achievements o our time. In August 1936, the Alexandra Palace transmitter i north London was in full operation, giving the first public televisio service in the world. On May 12, 1937, the Coronation processio was televized with much success. It was the first outside televisio exhibition of importance. Mr. Tremain points out that television i destined to play in the future a leading part both as a means o communication and as a means of instruction. When planning fo the future, it is important to bear this in mind. In England, as a result of pressure both from the cinema and radio industries, the experimental work being conducted for the purpose of extending the television service in the provinces was expedited. If a definite decision be taken with this end in view, we can look forward hopefully to it giving much direct employment in happier times.
"Significance of Television".
From *Nature* July 6, 1940.

10 YEARS AGO

THE 1980 general meeting of the International Whaling Commission at Brighton on 21–26 July will have on its agenda a call for a total moratorium on whaling. This is the third time that the issue has been raised; on previous occasions, however (1972 and 1979), the motion was amended to one for selective moratoria. This year, the proposal for a total moratorium is tabled, *inter alia*, by France, the Netherlands and the United States, and is felt to have an even chance of success.

As in previous years, defeat or amendment of the motion would probably result not from a change of heart by the pro-moratorium lobby but from a feeling that adoption of such a motion would push anti-moratorium countries out of the convention and therefore beyond international control.

There has been considerable speculation that, should the pro-moratorium advocates carry the day at Brighton, the Soviet Union and Japan might set up a rival commission of their own. Already the two countries have had some bilateral cooperation over quotas.

When, last year, the Soviet Union accepted the IWC's decision for a partial moratorium, in which fishing from factory ships would be confined to minke whales, it implemented this decision by ceding to Japan its North Pacific quota of 230 bryde whales in return for 300 of the less valuable minke whales from Japan's quota in the Antarctic.
"Whaling quotas: More wrangling".

New PHARMACOLOGY TITLES from Macmillan

Peptide and Amino Acid Transport Mechanisms in the Central Nervous System

Edited by L Rakic, Professor of Neurobiology and Biochemistry, Belgrade Clinical Centre; David J Begley, Lecturer, Department of Physiology, King's College London; Hugh Davson, Professor of Physiology, St Thomas Hospital, London and Berislav, Associate Professor, Belgrade University Institute of Medical Physiology

The way in which the brain regulates its internal environment separately and distinctly from the rest of the body has long generated intense interest and debate. Today, advances are being made at an ever accelerating rate. This volume addresses itself to regulation, within the brain extracelluar fluid, of peptide and amino acid levels, particulary those which are known or putative neurotransmitters and neuromodulators. Particular attention is also devoted to the way in which peptides may penetrate the blood-brain barrier or alter its permeability to other solutes. This volume is of vital relevance to anyone studying central nervous system disease, especially the fundamental problem of designing drugs and agents which will penetrate the blood-brain barrier and excert central nervous actions. The relevance to mental health and disease is also unquestioned.

Peripheral Actions of Dopamine

Edited By Christopher Bell, Department of Physiology, University of Melbourne, Australia and Barry McGrath, Monash University Medical School, Melbourne, Australia

This book reviews the current state of research in three main areas concerning the actions and significance of dopamine in the periphery: the source and effects of endogenous dopamine; the classification and distribution of, and the effects of activating, various populations of peripheral dopamine; and the therapeutic significance of dopamine receptor activation and renal disease.

Contents: Sources of Circulating Dopamine A Personal View. J-L. Cuche Dopamine Storage in Sympathetic Nerves. New Concepts in Depression

Pierre Fabre Monograph Series, Volume 2

Edited by M. Briley, Pierre Fabre Medicament, Castres, France and G. Fillion, Head of Neuroimmunoendocrinology, Pasteur Institute, Paris

Depression is increasingly seen as an important debilitating neurological condition. This book brings together a timely collection of results and opinions of the major preclinical and clinical researchers in the field of depression. In addition, a number of chapters concentrate on clinical or physiological phenomena associated with depression. The general attitude of the book is one of openness to new ideas several of which are presented here for the first time.

Contents: The Contributors Preface to the Series Preface Biochemical Mechanisms in Depression 5-HT and Depression Physiological Correlates in Depression From Experimental Models to Man Clinical Pharmacology of Depression and Associated Phenomena

1988 392pp 234x156mm Hardback £45.00 0-333-44133-8

INSECT COURTSHIP ROLES

Less light from spiral galaxies

Science in France

How much more would this ad have weighed if we had dotted all the i's?
Consult a METTLER DeltaRange balanc

Imagine a balance with the ability to change its readability. To solve riddles like the collective weight of all the dots on a page – without the need for a second, finer balance.
If you're imagining a METTLER Delta-Range balance, you're right on the dot. Its movable fine range lets one balanc do the work of two by giving you ten times higher accuracy, anywhere withi the entire weighing capacity. All with a simple press of the tare bar. And now, t size of the fine range on our PM models has been increased by 33%.
All of which spells out why a METTLER DeltaRange balance is the best value in weighing. And it's available exclusively from METTLER. For more information, give us a call. We'll fill in all the missing pieces... and dot all the i's.

QUIZ

Which procedure requires less than 30 minutes to separate supercoiled plasmid from chromosomal DNA?

1. CsCl

2. CIRCLEPREP™

ANSWER: Number 2, of course.

No matter how carefully you lyse cells, by whatever method, it is difficult to avoid some sheared chromosomal DNA in your plasmid preps. The CIRCLEPREP procedure specifically addresses the separation of chromosomal DNA from supercoiled plasmid, replacing the function of CsCl gradients without the investment in time or equipment. In fact, unlike any other, the CIRCLEPREP KIT allows the user to control the degree of chromosomal DNA elimination.

CIRCLEPREP™

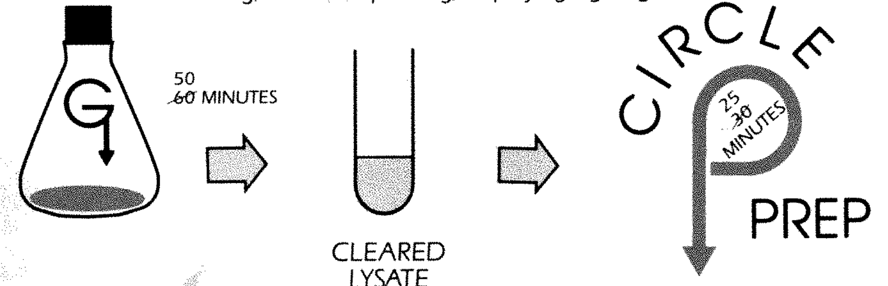
NOW EVEN FASTER
NEW SIMPLIFIED PROTOCOL

RAPID PLASMID DNA PURIFICATION KIT

SCALE UP OR DOWN TO DO 20-25 MIDI-PREPS OR 400 MINI-PREPS PER KIT

patent pending

Isolate preparative quantities of enzyme substrate-quality plasmid DNA in less than 90 minutes for immediate high efficiency use in cutting, ss or ds sequencing, amplifying, ligating and transformation into prokaryotic or eukaryotic cells.



CIRCLEPREP Kit, cat. #CP100

Kit contains all reagents necessary to grow cells, prepare cleared lysate, separate supercoiled plasmid from chromosomal DNA and purify preparative quantities of enzyme substrate-quality plasmid DNA.

EACH KIT: 20 to 25 midi-preps of 50 to 100 ug each or scale down to do as many as 400 mini-preps of 3 to 5 ug each.

STABILITY UNDER FIRE.

A NEW GENERATION OF HEAT STABLE VENT™ DNA POLYMERASES

STABILITY AT 100° C AND PROOF READING ACTIVITY

New England Biolabs, Inc. announces the first in a new line of DNA polymerases that remain active at 100° C. Vent™ DNA polymerase retains activity for over two hours at 100° C. while Taq DNA polymerase loses practically all activity in 10 minutes. This increased thermal stability allows experimental approaches never before possible.

In fidelity experiments, the proven 3′ to 5′ proof reading activity of New England Biolabs' Vent™ DNA polymerase results in fewer base-insertion errors than Taq DNA polymerase.

Thermal Stabilities of DNA Polymerases:

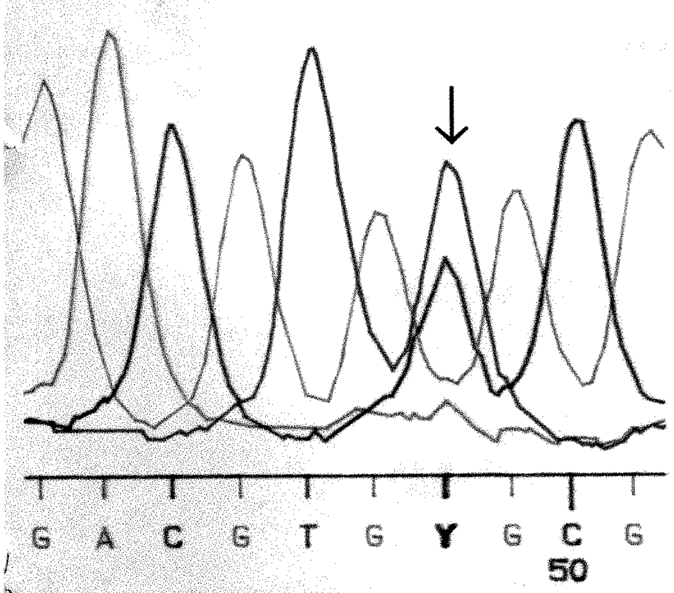
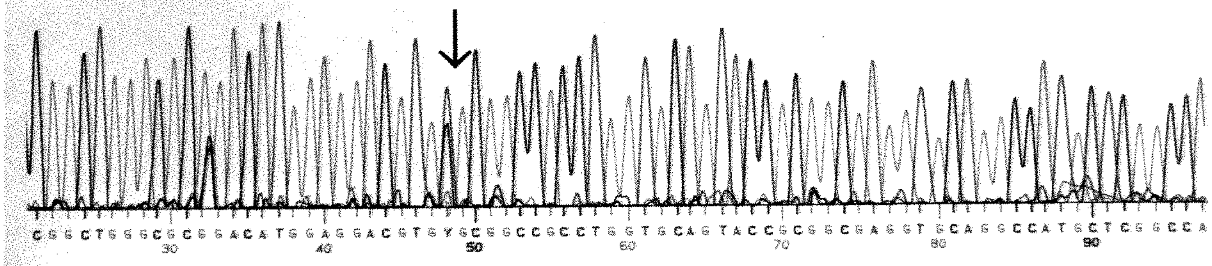
HARMACIA LKB BIOTECHNOLOG



Direct genomic solid phase sequencing of the human apolipoprotein E gene for diagnosis of a heterozygotic point mutation, Hultman and Uhlén (1990) submitted for publication.

Raw DNA sequencing data



Processed DNA sequencing data

Processed data is only as accurate as the raw data.

When you're looking at automated DNA sequencing systems, you should be sure to take a good look at the raw data. That's because raw data is the basis for the processed data. Raw data should be easy to read and to interpret.

Sophisticated software may be able to manipulate, evaluate and present raw data in a lucid format, but it can never eliminate inherent ambiguities.

The Automated Laser Fluorescent A.L.F. DNA Sequencer™ produces accurate and easily interpreted raw data. That's because it relies on simplicity. When the reaction chemistry is proven and the electrophoresis technology is efficient and the hardware has no moving parts, it's easy to obtain raw data that you can rely on.

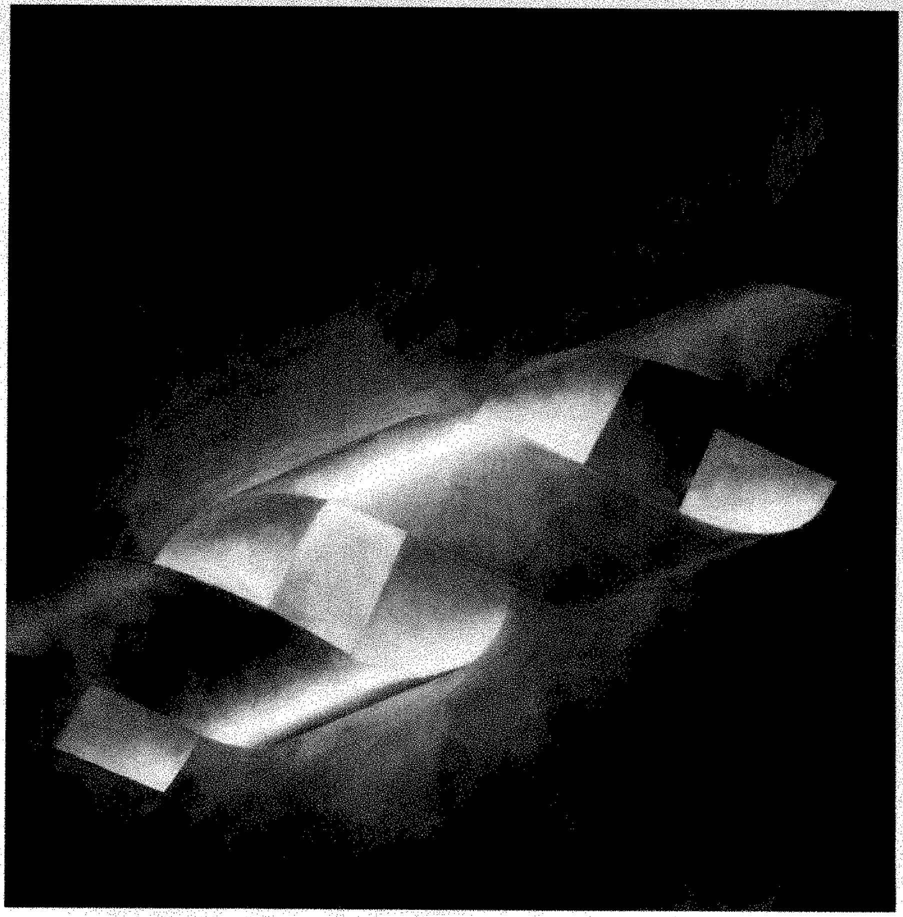
ECL



Light-based detection with oligonucleotide probes

Trying to choose between ^{32}P and a non-radioactive system?

The new ECL Oligonucleotide labelling and detection system complements our ^{32}P systems. We can now help you choose the technology, radioactive or non-radioactive, to best suit your experimental needs.

The ECL (enhanced chemiluminescence) systems are based on 5′-end labelling an oligonucleotide (through a 5′ thiol group) with the enzyme horseradish peroxidase.

In the presence of the ECL gene detection reagents an enhanced light signal is created.

- Especially suitable for detecting PCR amplified targets, colonies, plaques, dots and mis-match analysis. Also suitable for Southerns.
- <5 hours required to label an oligomer, hybridize and detect.
- Hybridizations often <1 hour and detection on film in minutes.
- Probes stable >6 months.
- Easy reprobing.

Products

ECL Oligonucleotide labelling system (sufficient to label 5 x 5μg of oligonucleotide)	RPN 2111
ECL gene detection reagents (sufficient for 4,000cm² of blots)	RPN 2105
ECL Oligonucleotide labelling and detection system (RPN 2111 + RPN 2105)	RPN 2113
C_6-thiol modifier A cyanoethyl phosphoramidite that allows a thiol group to be introduced to 5′-end during automated oligonucleotide synthesis.	RPN 2112

nature

12 July 1990
Vol. 346 Issue no. 6280

◀ In at least one species of katydid, variations in relative male and female parental investment determine the degree of competition for mates, lending support for a central tenet of sexual selection theory. Cover shows a female katydid on a 'kangaroo paw' plant feeding on spermatophore. Page 172. 'Science in France', pages 121–140.

THIS WEEK . . . THIS WEEK . . . THIS WEEK . . .

Dark stars

A survey of surface brightness of 16,000 spiral galaxies as a function of their inclination to the line of sight suggests that they are much more 'optically thick' than was supposed. If this is so, the amount of dark matter in these galaxies may be much less than previously thought. Pages 153 and 105.

Fossils with muscle

Rocks of the Santana Formation in Brazil contain many exceptionally well preserved fossils from the Lower Cretaceous period. In fossilized striatal muscle tissue from the fish *Notelops brama*, electron microscopy (page 171) reveals clear banding in the muscle fibres, and even cell nuclei. Similar details preserved in a pterodactyl wing illustrate the problems of interpreting such fossil evidence, page 116.

Retrovirus infections

Infection of neurons by a murine neurotropic retrovirus which causes spongiform degenerative changes in the brain, and the failure to detect viral envelope protein in infected neurons, raises the possibility that abortive infection of neurons or glia may be a factor in the pathogenesis of human retroviral diseases of unknown aetiology. Page 181.

Wilms' gene expression

The gene whose absence is believed to be responsible for Wilms' tumour is shown by Pritchard-Jones *et al.* on page 194 to be expressed in specific tissues of the developing kidney, which is consistent with the renal tumours and nephritis associated with the mutant gene.

Underground map

The detection of seismic reflections 110 km beneath ground level — the greatest depth so far investigated — paves the way for 'mapping' the base of the Earth's outer shell. Page 165.

Moving pictures

Neurons in the middle temporal area (MT) of the visual cortex show direction-selective responses to stimuli with properties suggesting that they underlie the perception of visual motion. This suggestion is strengthened by the demonstration that microstimulation of MT neurons biases the perceptual judgement of the direction of motion. Pages 174 and 106.

Getting complicated

The change from arid to humid climate in the Sahel and Sahara at the end of the last glacial period may not have been the gradual process assumed by many climate modellers. Pages 141 and 107.

Solid progress

US manufacturers will continue to lag behind Japan in the semiconductor industry — unless they change their ways. Commentary, page 101. On page 155, a step towards polymer-based electronic devices.

Methane controls

Tundra soils contribute 10% of the global atmospheric methane budget, but production of this 'greenhouse' gas would decrease as the soil dried out in the event of global warming. The tundras may thus provide a negative feedback on atmospheric methane. Page 160.

On target

The ability of excess E1a to 'squelch' transcription activated by its own 'activation region', but not that activated by 'acid blob' activation regions, suggests that it interacts with a distinct cellular target factor. Page 147.

Prion knowledge

Can the agents responsible for scrapie and bovine spongiform encephalopathy be transmitted to humans via sheep and beef products? See page 113.

Stop Unwanted Rearrangement Events.

Introducing Sure™ Competent Cells
10^9 Transformation Efficiency

Despite genetic improvements in commonly used strains, many DNA fragments, particularly those from eukaryotic organisms, have been deemed 'uncloneable' after repeated trials in a variety of restriction minus hosts.

Stratagene has designed the *E.coli* Sure™ strain*; a superior host for optimizing the construction of cDNA and genomic libraries and increasing the probability that individual clones reflect the genetic structure in the organism. The Sure™ strain's stability is due to uvrC, umuC, sbcC, recB and recJ mutations which stabilize inverted repeat sequences and Z DNA (1).

The Sure™ strain is completely restriction negative, carrying deletions of the hsdR, mcrA, mcrB and mrr genes. The absence of mcrA, mcrB and mrr restriction activity increases the size and representation of libraries constructed with methylated or hemimethylated DNA.

The Sure™ strain harbors a tetracycline-resistant F' episome carrying the lacI^{q}ZΔM15 cassette, making it suitable for enhanced blue/white screening on plates supplemented with X-gal and IPTG. It provides a stable environment for DNA molecules capable of assuming 2° and 3° structures susceptible to rearrangement. The Sure strain is thus suitable for cosmid, phage or plasmid libraries using the pWE cosmid (2), (3), the lambda ZAP® II vector (4), the pUC series (5), or the pBluescript® II plasmid (6).

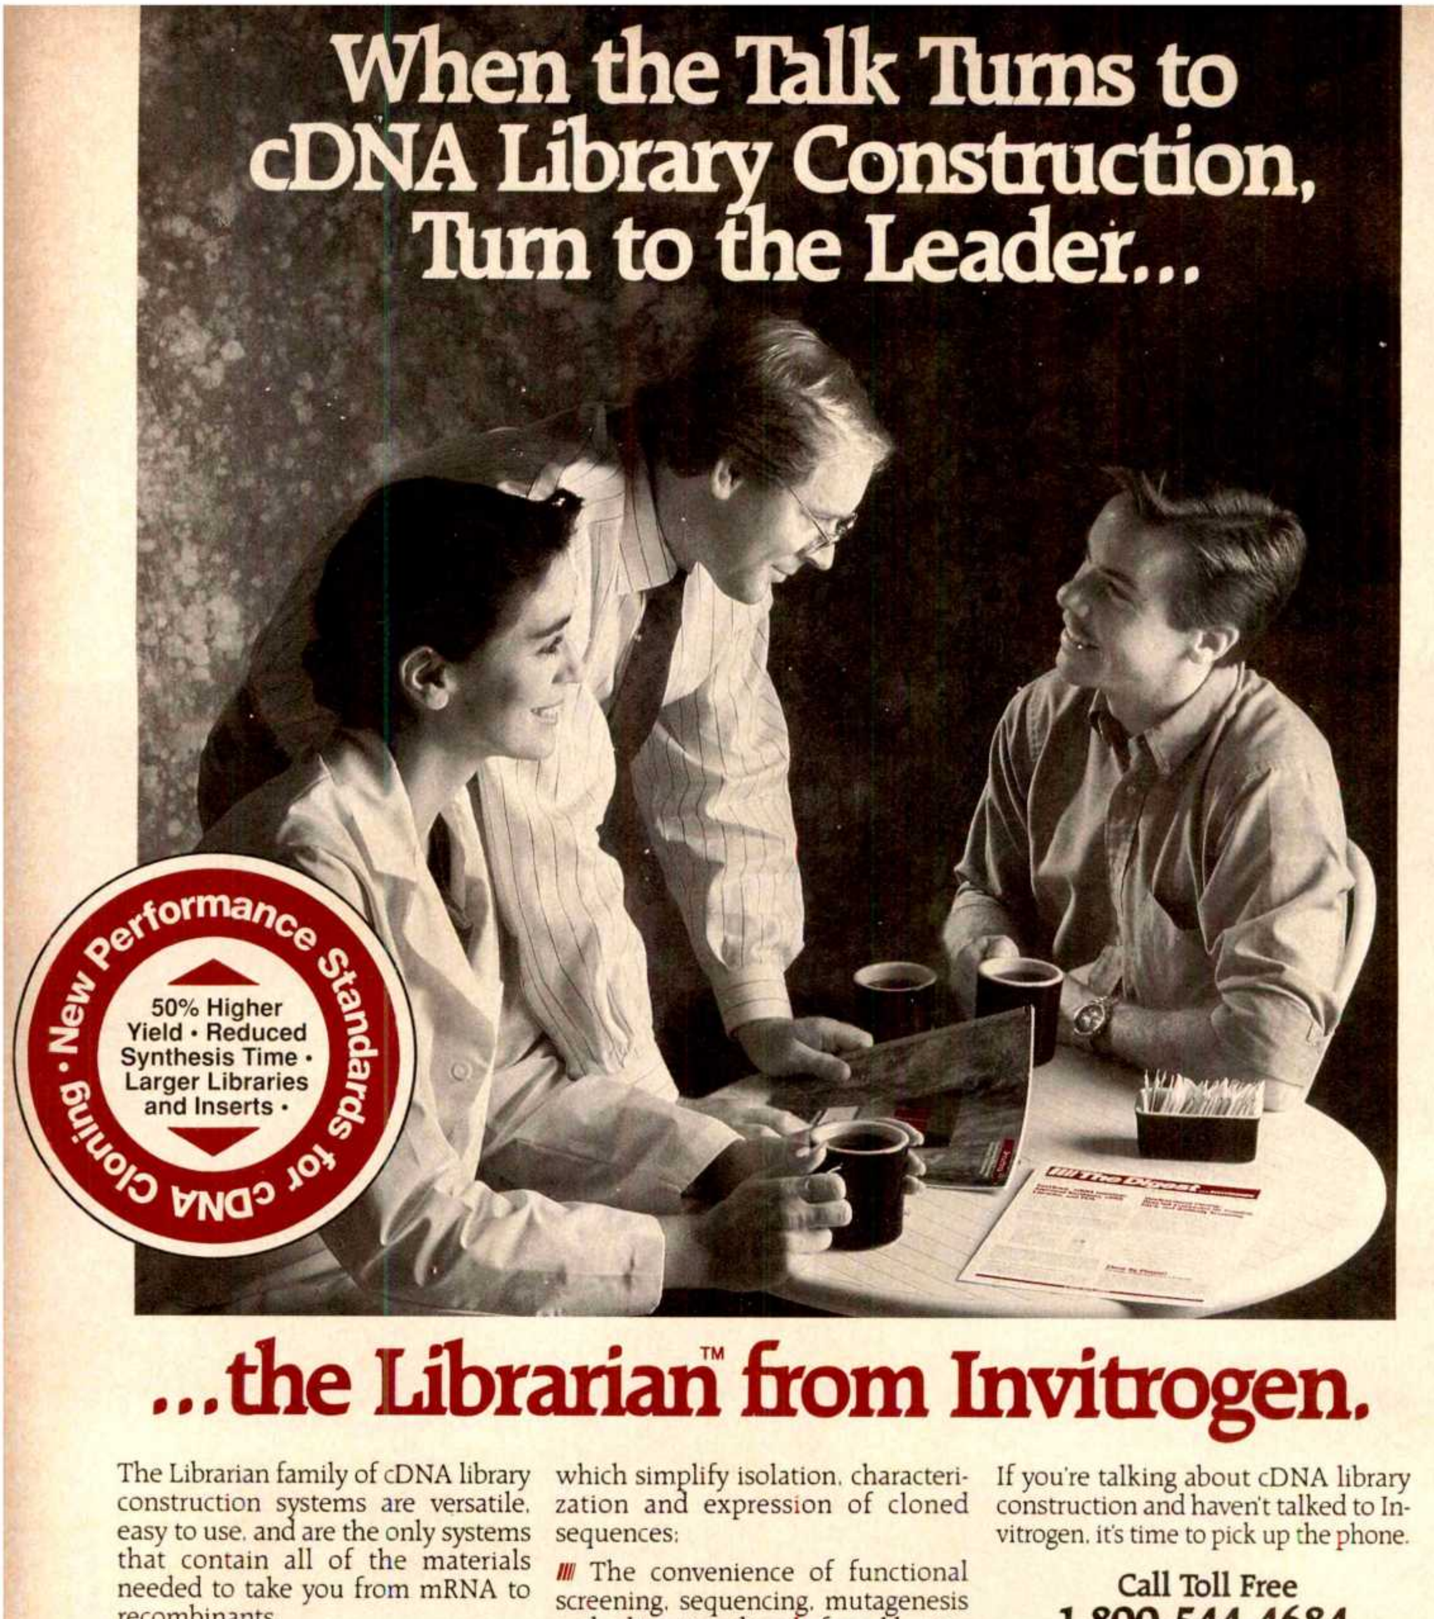
When the Talk Turns to cDNA Library Construction, Turn to the Leader...



New Performance Standards for cDNA Cloning •
50% Higher Yield • Reduced Synthesis Time • Larger Libraries and Inserts •
The Digest

...the Librarian™ from Invitrogen.

The Librarian family of cDNA library construction systems are versatile, easy to use, and are the only systems that contain all of the materials needed to take you from mRNA to recombinants.

The Librarians offer:

- Modular design that includes prepared vector, E. coli and all enzymes and reagents; quality controlled as a complete system for optimum efficiency;
- Your choice of mammalian, yeast, or prokaryotic expression vectors which simplify isolation, characterization and expression of cloned sequences;
- The convenience of functional screening, sequencing, mutagenesis and subtraction directly from libraries constructed in the Librarians phagemid vectors;
- A highly efficient method for size selecting cDNA generated by random or oligo dT priming;
- Technical service personnel with the experience to provide reliable information and assistance.

If you're talking about cDNA library construction and haven't talked to Invitrogen, it's time to pick up the phone.

Size up your DNA

Five reasons to use STEP DNA markers*

1. No more gaps; an even distribution of bands.
2. Fragments span the size range most frequently used for subcloning activities.
3. Recognizable pattern, easy to identify the relative size of your fragment without recourse to maps.
4. Sizes accurately determined, using 3rd order polynomials of sequenced standards. The relative size of experimental DNA bands on agarose is more accurately reflected than with sequenced standards.
5. The markers are available unlabelled or as biotin- labelled DNA.

A BRILLIANT NEW STANDARD IN NON-ISOTOPIC DNA DETECTION

Cambridge Research Biochemicals has created a new non-isotopic labelling kit for use with oligonucleotide probes. It's called E-Link Plus^{TM} and it uses Lumi-Phos^{TM} — a stable chemiluminescence substrate that gives detection sensitivities in excess of **one attomole** using normal X-ray film.

Which puts protocols for *Southern blotting*, *Northern blotting* and *dot blots* that use ^{32}P firmly in the shade.

E-Link Plus^{TM} — clear benefits

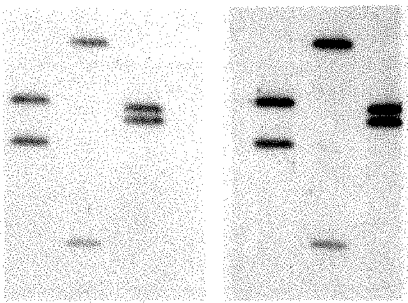
Easy-to-use: the kit contains all the reagents and a simple optimised protocol for the covalent labelling of oligonucleotides to alkaline phosphatase prior to detection.

Fast: reproducible conjugations require less than one hour hands-on time. Film exposure times are shorter than for ^{32}P.

Stable: unlike ^{32}P, conjugates have a usable lifetime of six months or more.

Versatile: for applications such as *in situ hybridisation*, where sensitivity is not paramount, the kit is available in a second format without Lumi-Phos^{TM} substrate. The E-Link^{TM} kit allows users to select whichever substrate is appropriate for their application.

If you're involved in the detection of DNA isn't it time you saw the light?



A. Autoradiograph B. Lumigraph^{SM}

DNA fingerprint of 3 genomic samples hybridised with:

A. Minisatellite probe labelled with ^{32}P: Film exposed for 6 hours
B. Minisatellite oligonucleotide alkaline phosphatase conjugate used with Lumi-Phos^{TM} substrate: Film exposed for 2 hours

AMS Biotechnology

No 1 in Europe
products for Immunology

Monoclonal antibodies for
- mouse, rat and human Ig Isotypes
- mouse Ig allotypes
- mouse H-2, Ia and lymphocyte surface antigens
- human HLA, DR, monocyte and other lymphocyte surface antigens
- human complements
- infectious agents and human hormones
- retinoblastoma gene products

plus kits for - mouse Ig isotyping
- mouse, rat, human hybridoma screening

* antibodies in purified, biotinylated, FITC, Texas Red, R-Phycoerythrin, alkaline phosphatase and horseradish peroxidase forms *

More rows about Europe's money

The British government is making a last-minute attempt to persuade the rest of Europe that it has a better way of creating a common currency. It has a good case, but one likely to be overtaken by events — and by the Deutschmark.

IF people contemplating marriage prudently anticipate as many of the consequences as they can, why should countries planning union be more casual? Mr John Major, the British Chancellor of the Exchequer, could usefully have used that argument when, last week, he launched his last-ditch campaign against the European Communities' plan to legislate for a single European currency. Major says that the plan now proposed in Brussels is a recipe for enormous intra-European resentment. There is no doubt that he is correct; it is obtuse of national treasurers elsewhere in Europe not to recognize as much. This unsolicited expression of support for Major's isolated position is not biased by the circumstance that his own proposals for the future — the coexistence of national currencies with the European Currency Unit (ECU) — coincides with the interim solution advocated by this journal a year ago (*Nature* **341**, 89; 1989).

The correctness of Major's position is well illustrated by the monetary union of the two German states from the beginning of this month. People in the East will now spend a substantial part of their incomes on the products of factories in the West, with the result that many — estimates range from 10 per cent to 25 per cent, but reality could be worse — will be thrown out of work. That prospect is palatable only because the special circumstances promise that West German investment in the East will be so substantial and so quick that the economic upheaval will be short-lived. Let us hope so, for the sake of the civility of the united Germany.

The Brussels plan for European monetary union being pushed by the Commission president, M. Jacques Delors, would effect for the whole of the European Commmunities the kind of monetary union East and West Germany agreed last week, but without comparable compensatory arrangements. It is astonishing that the weaker economies in the European Communities, Greece and Ireland, for example, so casually applaud the Delors plan. Major is rightly worrying about Britain's future.

There may yet be a solution. The meeting of the heads of the European Communities' governments last week in Dublin convened not just one, but two, constitutional conferences in December on monetary and political issues respectively. They should be rolled together, for the second could allow the decisions of the first to be made acceptable. The model here is that of the United States, which enjoys the benefits of monetary and political union within which 50 states retain a substantial degree of autonomy mistaken, in many a state capital, for sovereignty. In practice, the states raise funds from property and sales taxes and take responsibility for education, regional infrastructure and some aspects of welfare, while the federal government uses a nationwide income tax to pay for national defence and supplementary welfare costs. (The costs of federal research agencies such as the National Science Foundation and the National Institutes of Health are peanuts by comparison.)

In Europe, that arrangement is turned upside down. Defence and social security remain national responsibilities, financed by national income taxes, while the nearest thing to a central government (the European Commission) is financed by a sophisticated version of a sales tax, most of which is spent on keeping Europeans working as farmers when they should be doing something else. There is no mechanism by which economic imbalances will be offset by the flow of funds towards the poorer regions. (The European Communities have what is called a social fund, but it is too small to matter and is deliberately marginalized politically.)

Major's proper worry is that monetary union on the basis of fixed exchange rates (the ultimate Delors plan) will rob him and his successors of monetary freedom: interest rates will be determined by the market (and will be lowest in the most productive countries) while the device for repudiating debt called devaluation would be both illegal and impractical. (If West Virginia now sought to solve its economic problems by offering 90 cents for each federal dollar, it would quickly find itself in queer street.)

In the short run, Major is right; let national currencies and the ECU coexist while people get used to the idea, and so that the commercial banks that convert one European currency into another no longer enjoy a right to collect an arbitrary tax on every currency transaction. Further ahead, there can be no monetary union without preceding political union of some kind — at least an understanding of who pays for defence (and thus a common understanding of what defence is for) and a commitment by the rich towards the welfare of the poor. The sad truth about the argument about European monetary union is that there is as yet no serious constituency for either of these causes, and that December is not very far away. □

How did AIDS begin?

What is to be made of a death from pneumonia in 1959, after an apparent immunological collapse?

A THOROUGHLY compelling tale came to light in last week's issue of *The Lancet* — that of how it has been possible, by making use of the technique of the polymerase chain reaction (PCR) for amplifying pieces of DNA, to prove that a seaman who died at a Manchester (northwest England) hospital in 1959 most probably died of AIDS (G. Corbitt, A. S. Bailey & G. Williams, *Lancet* **336**, 51; 1990).

There are two things to say, of which the most obvious is that the report is another vivid attestation of the power of PCR to identify particular nucleotide sequences in tissues long since dead in all clinical senses. On this occasion, by good fortune, some samples of tissue from the dead man had been preserved in blocks of paraffin wax. What now unambiguously emerges is that the kidney, bone marrow, spleen and pharyngeal mucosa (but not samples of liver and brain) carry nucleotide sequences characteristic of the virus believed to be responsible for AIDS, HIV (human immunodeficiency virus). Like Lazarus, it seems, the dead (and their secrets) have been brought to life.

The interest of this development is that it will throw further confusion on questions of the origin of AIDS, of its apparently rapid spread in the past decade and of its long-term potential. The year 1959 is a significant one because it is that from which dates the earliest sample of blood which is known to contain antibodies against HIV, collected in Zaire. So at least two adults died of what would now be called AIDS in 1959. It is unlikely that they were the only victims in that year. And if there were at least two victims in 1959, how many were there in 1958, and 1957 . . . ?

Nobody, of course, can know these things for certain. But the infection appears to have been much the same in 1959 as it is now. The dead Manchester seaman appears to have infected his wife and she the youngest of their three daughters, both of whom afterwards died of a similar syndrome. For what it is worth, the fifties was also the decade during which immunodeficiency diseases came to the fore under the general heading of 'leukaemia'. There was a ready explanation at the time: that previously, without the benefit of antibiotics, people with immune deficiency such as that associated with leukaemia had died of chance infection. It would be surprising if those deaths did not include a sprinkling of AIDS patients. That would agree with estimates of the time since the divergence of HIV from the simian immunodeficiency viruses from which they appear to be derived (see, for example, T. F. Smith *et al. Nature* **333**, 573; 1988).

If there were sporadic AIDS cases during these years, why did the present spread of AIDS in developed countries not begin until the end of the 1970s? HIV is not especially infectious, has a long incubation time, but eventually kills those infected. The sad case of the Manchester seaman shows how an isolated case of infection may run into the sand, with personal tragedy but no spread of infection beyond the immediate family. Given HIV, the rate at which the infection spreads is determined by the rate at which infected people acquire and infect new sexual partners in the interval between infection and death, with the transfusion of infected blood, the use of infected hypodermic needles and maternal transmission amplifying the process. All that is now reasonably well understood, as is the truth that the spread can be controlled only by individual precautions to ensure that sexual intercourse does not lead to infection by HIV and that other high-risk behaviour is avoided. The high incidence of HIV infection reported from many African countries is a sign of the end-point which, it is to be hoped, will elsewhere be avoided. □

Moving the goalposts

Disappointment with the World Cup could be simply prevented in future competitions.

NOT for the first time, the competition called the World Cup has ended with players and spectators alike complaining of their disappointment. One BBC commentator was heard to declare that "This hasn't been the best World Cup in the world". But the faults of these competitions, and of the game of football which is their substrate, are well recognized.

This time, the complaint is that too many matches ended with neither side having acquired a score, so that a "result" had to be manufactured, for the convenience of the organizers, by means of a humiliating game of chance in which people kick a football just beyond the reach of a person called a goalkeeper. But that is a superficial issue. It is much more important that the game of football, as at present played, invariably yields such small scores that they cannot possibly be an objective measure of the relative quality of two teams.

Plainly, the game needs radical redesign so as to increase the likelihood that scores different from zero will result. As things are, it is probably fair to represent teams' scoring potential by a Poisson distribution of the form $P(N) = \lambda^N e^{-\lambda}/N!$, where $P(N)$ is the probability of scoring N in a particular match, when λ will be the mean score against comparable opposition. A team's opponents will presumably have a similar distribution, but with a different parameter, say μ. A football game is or should be an experimental test of whether the parameters λ and μ are significantly different. Karl Pearson's F statistic is the appropriate test, but whatever is done, it is inconceivable that there could be a valid test of quality in less than, say, 12 hours play, which would clog all the television channels. It would be simpler to set the goalposts further apart. □

Commission to keep whaling moratorium

■ Debate to be refought next year
■ Value of scientific whaling disputed

London

THE International Whaling Commission (IWC) decided to keep the moratorium on commercial whaling in place for at least another year at its annual meeting in Nordwijk, the Netherlands, last week. Iceland and Japan failed to win approval from the commission for commercial quotas for minke whales but catches as part of 'scientific research' programmes will continue, despite the opposition of most IWC members.

Iceland had asked for a commercial quota of 200 minke whales in the central north Atlantic Ocean and Japan for 50 in the Okhotsk Sea. The minke is the smallest of the great whales and was the last to be hunted.

The Icelandic and Japanese requests had been expected as the moratorium, which came into effect in 1986, was set for revision this year. But the timetable for revision incorrectly assumed that the procedure by which catch quotas were set would be overhauled successfully by 1990.

All agree that a new system is necessary. Quotas depend on accurate population estimates, and information on whales' rate of reproduction. But these estimates are notoriously inaccurate, so that even catches within an agreed quota might drive a managed stock to extinction.

The IWC's scientific committee has produced a shortlist of procedures that may produce quotas that will protect stocks from overexploitation. But repeated computer simulations of their effects on whale populations are still needed.

The three main whaling nations — Japan, Iceland and Norway — accept that a comprehensive review of the commercial moratorium will have to wait until the 1991 IWC meeting in Rekjavik, Iceland. But Lars Walløe, scientific adviser to the Norwegian delegation, believes the anti-whaling nations will delay the adoption of a revised quota system there.

Irrespective of any political pressure, Phil Hammond, a UK delegate to the scientific committee, doubts if a new quota system will be in place in time for Rekjavik. Scientists are uncertain of the geographical boundaries between genetically distinct stocks of minke whales, and have to develop a quota system that will not threaten individual stocks, irrespective of where the boundaries lie.

Even if the new quota system is ready by next year, the anti-whaling majority of IWC members is likely to vote to maintain the moratorium. The whaling nations may then carry out their long-standing threat to leave the IWC.

The controversial issue of whaling carried out in the name of scientific research is a more immediate concern. The scientific committee, meeting before the full IWC meeting, as usual disagreed over the merit of this year's research proposals. Like the full IWC, the committee is influenced by political considerations, with scientists representing the interests of whaling nations clashing with a committed core of anti-whaling biologists.

Debate over a Norwegian proposal to take five minke whales in the Barents Sea (to add to the 46 taken in the last two years) centred around the 'multi-species model' that Norway says will help the sustainable management of Barents Sea whaling and fisheries. Norwegian biologists plan to combine data on minke whale digestion and energetics with similar data for other species, to model feeding interactions.

But some members of the scientific committee doubt if the whale data, with such small sample sizes, will be useful. Sidney Holt, scientific adviser to the Seychelles delegation, argued that the Norwegians should first develop their model, and examine how the whale data will affect it, before taking more whales.

The much larger and ongoing Japanese programme on Antarctic minkes (see *Nature* **344**, 189; 15 March 1990) was the source of more disagreement. As in the past two years, Japan plans to take 300 minke whales, to estimate the age structure of the population.

Doug Butterworth, from the University of Cape Town, a scientific committee member not attached to any national delegation, presented analyses indicating that the Japanese data may be useful, allowing future quotas to be set with greater accuracy.But again, some biologists argued that the sample sizes are too small to estimate age structure. The committee needs a convincing analysis of the margin of error surrounding the age structure estimates, but is not satisfied that the Japanese have provided this. Although a catch of 300 minkes will not seriously deplete the overall Antarctic population (estimated at about 750,000), some biologists believe that the analysis should precede further catches.

Fukuzo Nagasaki, scientific adviser to the Japanese delegation, agrees that a sample of 300 minkes is "rather small", but says accurate age structure data will be collected in five or six years.

The full IWC meeting asked both Norwegian and Japanese governments to "reconsider" their permits for scientific whaling. Nagasaki says that some minor amendments to the research are possible, but the catch will go ahead. The IWC's constitution allows members to take scientific catches, irrespective of IWC resolutions.

The anti-scientific whaling lobby did gain a small victory, however, when a Soviet proposal to take up to 70 minkes and 30 fin whales in the Okhotsk Sea was withdrawn. The Soviet plan was received poorly by the scientific committee, as the aims and methods of the research were unclear, and no Soviet scientists attended to explain the research. **Peter Aldhous**

Reduction request

London

THE IWC, concerned about the huge catch of dolphins and porpoises in Japanese waters, has asked Japan to reduce its catch of Dall's porpoise to below 10,000 animals a year — the number taken in 1986. A report from the British pressure group, the Environmental Investigation Agency, published last month, estimated that at least 50,000 dolphins and propoises are now killed each year off the Japanese coast.

Since the moratorium on commercial great whale catches came into effect in 1986, the shortage of whalemeat for the Japanese market has made porpoise meat a precious commodity, increasing the Dall's porpoise catch to about 40,000 per year in 1988. Although the 1989 catch was somewhat reduced, at around 30,000 animals, this figure still "must be unsustainable", according to one participant in last week's meeting. The entire population of Dall's porpoise in Japanese waters was estimated at only about 100,000 individuals in 1986.

But the resolution, proposed by a number of anti-whaling countries including the United Kingdom, can at most be described only as a forceful request. Fukuzo Nagasaki, scientific adviser to the Japanese delegation, acknowledges that the Dall's porpoise is a genuine concern. But he offers little hope that the new resolution will be obeyed. Although the Japanese government is trying to reduce catches, Nagasaki says, the fishery operates through a system of licences for boats, rather than fixed quotas.

A quota system would take "a long time" to implement, he says.

The Nordwijk meeting also passed a resolution asking IWC's scientific committee to gather information on the size of small cetacean stocks around the world, with the aim of presenting a report to the UN conference of environment and development in 1992. Peter Aldhous

SILVER SPRING MONKEYS

Then there were four

Washington

THE long war over the fate of the 'Silver Spring' monkeys entered a new phase last week when three of the remaining seven monkeys kept at the Delta Regional Primate Research Center in Louisiana were killed after a series of experiments were carried out on their brain activity. As in the past, neither side in the fight over the fate of the monkeys was willing to soften their rhetoric. Both the animal rights groups and the congressmen who regard the monkeys as symbols of laboratory mistreatment of animals, and their opponents in the research community and the National Institutes of Health (NIH) continued to denounce each other's motives.

The office of Congressman Robert Roe, which tried unsuccesfully to have experiments delayed until this week in order for Roe to discuss the monkey's fate with William Raub, the acting head of NIH, was scathing in its criticisms. Gregory Simon, staff director in Roe's office, described NIH's decision to kill the monkeys as "a vulgar display of muscle", which appeared to be designed "merely to make the point that the scientific community is totally in control of animal research and will not let anybody else influence the way it is done". Roe's office threatened public hearings on NIH's conduct and renewed efforts to pass a bill that would force NIH to send the remaining monkeys to an animal sanctuary.

People for the Ethical Treatment of Animals (PETA), the animal rights group which has made the monkeys into a public issue, erected a protest sculpture, depicting the 'torture' of a monkey on a laboratory apparatus, outside the Department of Health and Human Services. PETA reminded the press that the monkeys are still the biggest cause of public appeals to the White House, claiming that it had received 45,000 letters last month asking Barbara Bush, the wife of the president, to free them.

But NIH continues to point out that it has acted correctly and according to the demands of the law. Raub said that it had sought permission to kill the three animals after their health deteriorated and veterinary experts had recommended euthanasia. "The department has made its intentions known for a long period," says Raub, "once the court matters were cleared up it was our obligation to proceed. A delay for an arbitrary period of time would be totally contrary to the representation we made to the court, Congress and everyone else."

Animal rights groups and NIH have agreed on virtually nothing from the start fo the Silver Spring saga. According to PETA, when police recovered 17 of the crab-eating macaques from the Silver Spring laboratory of Edward Taub in 1981, they found evidence that the animals had been mistreated. Taub, they claim, was later convicted of cruelty to animals in a Maryland court. Supporters of Taub disagree, pointing out that Taub was cleared of all charges on appeal and further exonerated in independent investigations.

The latest twist in the saga came after the Physicians Committee for Responsible Medicine, another animal welfare group, failed after a long period of court action to obtain an order to block the euthanasia of three of the monkeys.

Alex Pacheco, spokesman for PETA, says that for "NIH to paint this as a mercy killing is just another lie". He believes that the monkeys were used in experiments and then killed so that NIH could justify having refused for years to release the animals to a sanctuary. PETA claims that the experiments are bogus and points out that in 1985, Raub, who was then Deputy Director of Extramural Research at NIH, wrote that "we have no research protocols, ongoing or planned, for which these animals are appropriate".

Raub says that "it has been explained many times over that the letter was a response to a very narrow proposal". Since then times have changed and the monkeys have emerged as an extraordinarily valuable resource, not for the experiments on rehabilitation from injury which were originally planned, but to test new hypotheses concerning the degree to which the brain is able to reorganize itself after inputs to specific regions are lost. The Silver Spring monkeys had had nerves cut in their forearms.

Experiments conducted on the three monkeys before they were killed revealed "massive reorganization" in the cortex, according to Timothy Pons of the National Institute of Mental Health who lead the team. The data seem to confirm those gained from experiments carried out on one of the monkeys which was killed earlier this year (see *Nature* **343**, 581; 15 February 1990). With data from four monkeys in hand, Pons says he will prepare a scientific paper for publication.

The significance of the science is not really the problem bothering Roe, who is chairman of the House of Representatives Committee on Science, Space and Technology, so much as the way in which the sensitive issue of the monkeys has been handled. Roe's staff members have spent the last six months, according to Simon, "working with PETA and with NIH to come up with the middle ground — an independent panel that would review the disposition of the monkeys". When agreement had apparently been reached, Simon claims that NIH changed its mind. "Once they won in court everything changed and we're talking strictly 'might is right'", says Simon.

But Raub says that it was incorrect to say that NIH backed out of the negotiation. He said he had found it very "disheartening how little progress we made and how far apart the views of the animal rights groups and the NIH were. As we were making little progress there and the court restraints were being resolved a hundred per cent in our favour, and these animals had been judged by experts as candidates for euthanasia as far back as 1988, our obligation under the Animal Welfare Act was that we had to proceed with [the euthanasia] of those three animals".

AUSTRALIAN SPACEPORT

Soviet rockets gain US go ahead

Washington

PROSPECTS for the Australian Space Base at Cape York in northern Queensland are once more looking bright after US President George Bush indicated last week that he would not prevent US commercial satellites from being launched on Soviet-built rockets.

A major problem for the base has been that its likely customers were US companies wanting to launch US-made satellites while its cheapest source of launch vehicles lay in the Soviet Union. Until last week, the United States had objected to Soviet launches for US satellites, partly because they feared 'unfair' competition for domestic launches from state-subsidized Soviet organizations and partly because they feared that sensitive satellite technology might get into the hands of Soviet technicians.

The Cape York base, which will lie conveniently close to the equator, will cost around A$350 million to build and could be ready for its first launches in 1995. The project is entirely commercial and is backed by a large Australian property developer, but the contract for running the base seems likely to go to a US company or to British Aerospace. It is not yet certain that the spaceport will be built, as environmental impact studies have yet to be completed and objections from aboriginal groups considered (see *Nature* 343, 400; 1 February 1990).

Tougher competition for satellite launches is bound to follow the entry of Soviet vehicles into the field, alongside Arianespace which is already well established, and the several US companies that are just beginning to provide commercial launches. A controversial US decision made last year also gave limited rights to the Chinese to launch US satellites.

AIDS POLICY

Slanging match with Sullivan

Washington

RELATIONS between the US government and AIDS activists took a turn for the worse last week when Health and Human Services Secretary Louis Sullivan released a statement calling on health officials to avoid all but "necessary and productive" dealings with the radical protest group ACT-UP (AIDS Coalition to Unleash Power).

The statement is Sullivan's response to a noisy demonstration, led by ACT-UP, which drowned out his closing speech at last month's International Conference on AIDS in San Francisco. Upset by the attack, during which he was pelted with wads of paper and other makeshift missiles, Sullivan now says that he will not "let [his] department be used as a punching bag" or "have dealings with people who behave as ACT-UP did".

Peter Staley, a spokesman for ACT-UP, says that initially his organization took Sullivan's statement "very seriously". If the threats implied by this "politically naive" statement were carried out, says Staley, "it would be tantamount to a decaration of war".

But the Secretary's bark may well prove bigger than his bite.

When pressed for details, James Brown, a spokesman for the Public Health Service, was unable to give specific examples of the kinds of dealings with ACT-UP that will be curbed, although he said that the positions currently held by members of the group on research advisory panels are not in jeopardy. The Secretary will not stop "certain programmes" from drawing on ACT-UP's knowledge and expertise, Brown said.

ACT-UP says that so far there has been no evidence of any pressure on their many contacts in the Food and Drug Administration and National Institutes of Health (NIH) to stop communicating with its members.

Sullivan's words come at a time when activists and public health officials, particularly at the Food and Drug Administration and NIH, are nurturing a growing relationship. Members of ACT-UP currently sit on two of NIH's research advisory panels and expect to be awarded more committee places when the AIDS Clinical Trial Group at the National Institute of Allergy and Infectious Disease, which oversees the bulk of US AIDS research, is opened up to community representatives later in the year. "We certainly hope those won't be jeopardized", says Staley.

David Concar

AIDS EPIDEMIOLOGY

Another early case identified

Washington

THE date of the first known death from AIDS has been pushed back to the 1950s. Researchers at the medical school of Manchester University, England, have found evidence of HIV (human immunodeficiency virus) genetic material in tissue specimens from a 25-year-old caucasian seaman who died of severe pneumonia in Manchester in 1959.

Previously, the earliest recorded cases of HIV infection, identified retrospectively, were in three members of a Norwegian family who contracted AIDS in the 1960s and died in 1976. HIV antibodies have also been found in a blood sample collected from a patient in Zaire in 1959 — but in that case there is no evidence that the patient died from AIDS.

The new finding will not initiate a rethink in the epidemiology of HIV infection. According to Roy Anderson of Imperial College in London, epidemiological analysis of high present-day infection rates in places such as Malawi indicates that HIV must have been present in Africa for at least 30 to 40 years. More reports of early sporadic cases of AIDS will emerge, says Anderson, as researchers look back over the records. He also emphasizes that the Manchester seaman represents an unlikely point of origin for the current AIDS epidemic in Britain.

To obtain evidence for HIV infection, the Manchester researchers used the polymerase chain reaction (PCR), a technique that allows trace amounts of genetic material — in this case proviral DNA — to be amplified so that its identity can be determined using a DNA probe. One drawback with PCR is its sensitivity to contaminants, a problem which in the past has led to false results. Gerald Corbitt, one of the three researchers who reported the case in the British medical journal *The Lancet*, says that every precaution was taken to prevent contamination of tissue samples. They performed the analysis in a "remote" laboratory and their PCR assay gave the same result when repeated on different tissue samples.

The researchers do not yet know whether the patient was infected with HIV-1 or HIV-2, but are planning to sequence the proviral DNA to find out. Their main limitation is a dwindling supply of genetic material.

Sadly, there is little information on the seaman himself — his earlier medical history and the countries he visited before 1959 are apparently unknown.

David Concar

BIOLOGICAL WEAPONS

Lawyer talks tough

Boston

IN the coming months, many biomedical researchers are likely to receive a disturbing memorandum in their mail, warning them that their research could be breaking the law and they they could be punished by imprisonment for life. The memorandum will come from the office of Francis A. Boyle, a professor of international law at the University of Illinois at Urbana-Champaign who was instrumental in drafting recently passed legislation which incorporated provisions of the international Biological Weapons Convention into US domestic law (see *Nature* **345**, 192; 17 May 1990).

Boyle's memorandum, addressed to "all life science researchers" and circulated first to several scientific publications including *Nature*, alerts researchers to the provisions of the Biological Weapons Anti-Terrorism Act of 1989, Public Law 101-298. In effect, the law makes it a federal crime for a US citizen "knowingly" to develop, produce, stockpile, transfer, acquire, retain or possess "any biological agent, toxin, or delivery system for use as a weapon", or to aid a foreign state or any organization to do so.

Chuck Dasey, spokesman for the Army's Medical Research and Development Command, says that the Army has abided by the Biological Weapons Convention since its inception and thus by definition abides by the new legislation as well.

In a telephone interview last week, however, Boyle stated that the Army's contention is precisely what may now be challenged through either civil or criminal lawsuits involving specific research projects. In his memorandum to researchers, Boyle states that in his "professional opinion" many research projects that have already been funded by the US Department of Defense's Biological Defense Research Program (BDRP) "raise serious compliance problems" with the new law. Consequently, Boyle urges researchers who are receiving or applying for funding from the BDRP to "obtain legal advice and counsel from a competent attorney" about their research or grant application.

Boyle is not shy about his opposition to the BDRP programme. He stresses that in his view, "the first step is to warn researchers about the law" in the hope that they will look carefully at whether their work is fully in compliance. For researchers who continue to receive military funding, however, Boyle acknowledges that he may be personally involved in a legal challenge against them in the future if their work appears to him to stand in violation of the law.

HIPPARCOS MISSION

And now some good news

Paris

AFTER 11 months of calculation and rethinking, scientists at the European Space Agency (ESA) now believe that the seemingly ill-fated astronometry satellite, Hipparcos, will be able to perform its mission successfully after all. A request for ESA to build a follow-up, Hipparcos 2, has been dropped.

Hipparcos was launched last August by an Ariane rocket with the intention of gathering information on the position, proper motion and distance of 120,000 stars to a new order of precision. The launch itself was perfect — but then the apogee boost-motor failed, leaving the satellite in a highly elliptical orbit, rather than the geostationary orbit that was originally planned (see *Nature* **340**, 581; 1989). The load thus put on the satellite's three solar arrays seemed likely to limit the mission to a duration of six months, rather than the planned four years. Data collection also became a problem as the elliptical orbit put the satellite out of reach of a single tracking station and transmissions were regularly obscured as the satellite passed through the Van Allen belts.

Since then, help to track Hipparcos has been found at ground stations in Perth (Australia), Kourou (French Guiana) and Goldstone (United States), adding to the planned activities at Odenwald in West Germany. That means that the satellite is visible 93 per cent of the time and useful observations can be made 60 to 70 per cent of the time.

The future of the mission depends on the rate at which voltages from the solar panels decline. Mike Perryman, Hipparcos project scientist at ESA, last week said that projections based on rates collected over several months suggest Hipparcos may last two to three years "or four or even longer". That will allow the 120,000 stars of the input catalogue to be positioned with 10–20 milliarc accuracy, still, according to Perryman, 10–20 times better than could be achieved from the ground.

For Perryman, the effect of the failure is now on the quantity of observations, not their quality. "We cannot retrieve quite as much data, but for the 70 per cent of the time when we do get data, the quality is outstanding. We are delighted." Over 5 million observations have already been made of the 120,000 stars.

An 11-man enquiry board set up to investigate the failure of Hipparcos submitted its final report and recommendations last week. French defence department missile expert Daniel Reydellet, who chaired the inquiry board, said in Paris that an 'off-the- shelf' component in the ignition circuit of the apogee booster motor — the through bulkhead initiator (TBI) — apparently did not work. But Reydellet was reluctant to say whether the TBI, made by the California-based company, Hi Shear, was faulty. The TBI depends for correct functioning on pulses from other parts of the ignition circuitry.

The report neverthless suggests that Hi Shear's reputation with the US National Aeronautics and Space Administration may have dazzled ESA engineers into foregoing quality control checks. When, as part of the inquiry, experts visited Hi Shear, Reynellet said they found that TBIs originating from the same batch as the one used in Hipparcos had "disappeared", thereby ruling out fresh tests. Because the components can be used only once, statistics from the testing of a whole batch are needed to assess reliability. Neverthless, analyses being carried out by ESA have suggested that quantities of explosive may have been only just within the required specifications.

Wise after the event, the inquiry board has recommended that, when off-the-shelf components are bought in future, ESA engineers should monitor manufacture more closely. But, given the complexity of modern satellites, this may not be realistic.

Peter Coles

EUROPEAN SPACE PROGRAMME

Columbus shipwrecked?

Munich

A SMOULDERING dispute over the West German space programme flared into life again last week when the 1991 budget of the West German Research Ministry (BMFT) was announced. Space research and technology accounted for half of the 4 per cent increase in the budget, prompting renewed criticism from the opposition parties that BMFT was taking money away from other areas by investing so much in manned space flight.

With the estimated cost of the European space station Columbus, which is supposed to complement the US space station Freedom, having risen by thousands of millions of dollars, West Germany has found its role as main developer of Columbus, bearing 38 per cent of the cost, increasingly difficult to shoulder. When the European Space Agency (ESA) council decided in 1987 to begin three linked space projects — Columbus, the space shuttle Hermes and a heavy payload rocket Ariane-5 — the total cost was estimated at DM 21,000 million ($12,800 million).

Since then, the price has risen to an estimated minimum of DM 30,000 million, according to opposition members of the West German parliament. BMFT refused to confirm any such figure, but admitted that large increases would be necessary in 1992 and beyond to cover the rising cost of the programme. West German Research Minister, Heinz Riesenhuber (Christian Democrat), has promised not to let space research take more than 22 per cent of BMFT's budget. That proportion is now 20 per cent.

Columbus is meant to be both a vehicle for basic research in microgravitation and a platform for industrial research and development, but critics claim that neither goal will be met by the current plan. Opposition Social Democratic parliamentarian Edelgard Bulmahn doubts that the latest US plan for space station Freedom — to use it as a stopping-place for missions to the Moon and Mars — is compatible with using Columbus for microgravity research.

Anticipating a major budget battle, BMFT requested as early as 1987 that ESA cut its budget for the three projects by 15 to 20 per cent. But Buhlman says that cuts of this size would reduce the amount of new technology that European countries could develop, forcing ESA to buy much of the needed technology from the United States.

The members of Helmut Kohl's centre-right coalition gave a vote of confidence to Columbus last month before parliament adjourned for the summer. But the support may be conditional. Christian Democrat parliamentarian Christian Lenzer says he is "totally against building something that industry is not interested in using," sowing the seeds for a conflict with BMFT, which defends the project as an important investment in basic research. And a spokeswoman for the prime contractor for Columbus, MBB-ERNO in Bremen, said that "it will take 15 years" before the space station "becomes a business" the way that satellites or launch vehicles have.

Adding to the confusion, an ESA review board gave the MBB-ERNO proposal a low rating; the proposal was judged to be "of a generally low level of quality", and the "quality and accuracy of the cost data" was declared "totally unacceptable, with an extremely low level of credibility". An ESA spokesman said it was normal for a large proposal to receive a negative evaluation early in the approval process.

Next year, ESA member states will meet to decide how to proceed with the three space projects. If costs rise more than 20 per cent from original estimates, member states have the option to withdraw from the programme.

Steven Dickman

SPACE SHUTTLE

More trouble for high fliers

Washington

THE temporary disablement of two space shuttles by leaks in the hydrogen feeder lines between the external tank and the orbiter is almost certain to bring extra delays to one or more long-planned astronomy missions, adding to the pain caused by the revelations of manufacturing flaws in the Hubble Space Telescope (see *Nature* **346**, 3; 1990).

Astro-1, an ultraviolet and X-ray astronomy package (see *Nature* **345**, 375; 1990), is waiting for space shuttle Columbia to be repaired after a hydrogen leak was detected shortly before launch. The Gamma-Ray Observatory (GRO) is supposed to fly on shuttle Atlantis in early November, but Atlantis is now stranded on the launch pad at the Kennedy Space Center, Florida. In the meantime the joint US-European solar probe Ulysses must be launched by Discovery in October so that Jupiter is in the right place to give it a gravity-assist into a polar orbit around the Sun. Even if Colmubia or Atlantis were fixed in the next few weeks, the chances are high that Astro-1 or GRO would have to be postponed to let Ulysses fly on time.

The leak in Atlantis was discovered after NASA (National Aeronautics and Space Administration) mission controllers decided, in the light of their experience with Columbia, to conduct a pre-launch 'tanking test' in which the external tank was filled with hydrogen as it would normally be just before launch. They detected a small hydrogen leak, and postponed the Atlantis flight while it and Columbia were investigated. By this time, the various 'umbilical' pipes connecting Columbia to its external tank had been taken apart and tested individually, but the leak could not be reproduced.

Last weekend, NASA engineers tested Columbia's reassembled umbilical system at the Rockwell Downey company, near Los Angeles, where they were built.

This week, Atlantis was being prepared for a new launch-pad test, in which various parts of the umbilical will be surrounded by sealed bags in order to determine which part of the assembly is leaking.

How the launch schedule will be put back together depends on the amount of work needed to fix the leaky sections. If repairs can be made on the launch pad, Atlantis and its secret payload would be sent off as soon as possible, which would probably delay the launch of Astro-1 until after Ulysses. If Atlantis has to be rolled back off the launch pad to be repaired, Columbia and Astro-1 could be launched instead, but then GRO could not be launched until Atlantis's Defense mission had been completed.

David Lindley

LAWRENCE LIVERMORE LABORATORY

Bargain hunters' paradise in California

Washington

LAWRENCE Livermore Laboratory may be one of the largest US nuclear weapons research and development laboratories, with a strong reputation for its 'Star Wars' research, but it sounds a lot more like the thieves' bazaar of old Baghdad in the just published report of an investigation by the General Accounting Office (GAO).

The report says that equipment worth more than $45 million has vanished from the laboratory, which is managed by the University of California, including 49 microcomputers, 205 typewriters and word processors, 841 pieces of video equipment, 388 cameras and related equipment and thousands of calculators. Where has everything gone? A statement put out last week by the office of congressional strong man John Dingell, chairman of the House of Representatives Energy and Commerce Committee and its oversight and investigations subcommittee, noted that allegations had been made at a congressional hearing that "laboratory equipment, such as computers, was stolen and traded for drugs". Dingell, who ordered the GAO investigation, claims that at the laboratory "[w]e have seen drug use, cover-ups, retaliation against concerned employees, poor safety and poor security".

The Department of Energy (DoE) disagrees. In a reply, DoE diplomatically thanks Dingell for his interest, saying in a statement from its San Francisco office that it "consider[s] the findings helpful to improve property management at the lab" and that "improvements are under way". But it also says the laboratory has already located 98 per cent of the 'missing' property. According to DoE spokeswoman Caroline Powell, the San Francisco office has checked that the property is really in place. She says of the GAO failure to find many items, "maybe the thing was in a desk draw and they didn't ask the person who was responsible".

GAO has yet to report on a separate investigation into whether any nuclear materials or classified documents are missing from the laboratory. Dingell has promised to hold hearings later this year to examine the report and DoE's claims.

EUROPEAN SCIENCE

New Framework row

London

PLANS by European Community (EC) research commissioner, Filippo Pandolfi, to concentrate EC basic science spending almost entirely on postdoctoral fellowships have set him at odds with member states' representatives on CREST, the EC's scientific and technical research advisory committee. The disagreement could delay spending on basic science through the Framework programme, which supports all research and development efforts in the EC.

EC funds for basic science are set to increase under the third Framework programme, which will run from 1990 to 1994. The increase itself has caused apprehension in some members of the UK research councils, who fear that UK spending through the EC will be taken from the domestic British science budget (see *Nature* **345**, 376; 31 May 1990). But Pandolfi's decision to initiate a 'human capital and mobility' programme which would support several thousand postdoctoral positions has attracted wider opposition.

Only Italy, the present incumbent of the EC presidency and anxious to avoid rifts, has so far not come out against Pandolfi's plan.

Pandolfi argues that promoting the exchange of young scientists between EC member states is useful because it is not strongly supported by individual states. But CREST is concerned that there simply will not be enough young scientists to fill the places, and in any case wants a more diverse programme, with support for postgraduate scientists and large research institutes.

Although the proposed 518 million ECU (1 ECU = £0.70) human capital and mobility programme may include some support for applied science, it is envisaged that it will largely take over from Framework's SCIENCE programme, which is now the centrepiece of EC basic research support.

Supporters of the present diversified system point to the continued success of the SCIENCE programme's research projects, particularly the huge collaborative project on NdFeB alloy-based magnets (see *Nature* **338**, 734; 1989), which has given Europe the lead in this area. These large-scale projects do, in any case, support a number of postdoctoral researchers.

The current SCIENCE programme is due to end in 1992, but Pandolfi says he plans to fund a continued programme up to 1994. This will depend on additional money becoming available, however. Sir Peter Swinnerton-Dyer, chairman of the committee that allocates funds under the existing SCIENCE programme, is concerned that there could be a delay in getting the new programme under way, if CREST and Pandolfi cannot quickly reach a compromise.

Peter Aldhous

EUROPEAN NUCLEAR POWER

Not in my back yard

Munich

As the barriers between Eastern and Western Europe come down, some nuclear power plant operators in the West are wondering if they may not now have a golden opportunity to set up some of their unpopular generating facilities next door. The Czechoslovak government has already begun negotiations with French and German companies to build plants at the Temelin site, near the Austrian border. The plants would be financed by selling electric power to Italy, transmitted via high-tension cables running through Austria.

The idea of building new nuclear plants in Czechoslovakia is controversial, especially in neighbouring Austria, which abandoned its own nuclear programme in 1987. Anti-nuclear activists based in Austria have been campaigning for years against existing Czechoslovak reactors.

Nevertheless, there are clear benefits for Czechoslovakia in expanding its nuclear programme in this way. It could gain access to important Western technology and at the same time reduce its dependence on high-sulphur coal, which has devastated the environment (see *Nature* **344**, 91; 1990).

Czechoslovakia currently derives 27 per cent of its electricity from nine Soviet-built nuclear reactors at three sites. Another seven reactors that are under construction will raise dependence on nuclear power to 45 per cent by the year 2000. The design of two reactors, at Bohunice near the Austrian border, has been criticized as fundamentally flawed. They are of the same type (VVER 440-V 230) as those at Greifswald, East Germany, which were last month judged to be hopelessly unsafe by a West German safety commission and ordered to be shut down. There are four reactors of the same type still operating in Bulgaria and four more in the Soviet Union (see *Nature* **344**, 282; 1990). The remaining seven Czechoslovak 440 MW reactors are of a slightly more modern design.

So far, the newly elected democratic government of Czechoslovakia has continued its Communist predecessor's support for nuclear power. As recently as 27 June, an adviser to the now-defunct Ministry for Fuels and Energy, Frantisek Suranski, declared on Austrian television that Czechoslovakia "sees no reason or option to give up nuclear power now". Even the activist Environment Minister for the Czech republic, Bedrich Moldan, has said that he favours the continued operation of existing nuclear plants and the completion of plants under construction.

Prime Minister Marian Calfa announced on 3 July that several coal-burning plants in northern Bohemia would be closed by the end of the year. That decision will put more pressure on nuclear plants to fill the resulting energy gap. A moratorium declared in January by the interim government on construction of the two newest 1,000 MW plants at Temelin does not mean that nuclear power is out of favour — these are the plants that the government may replace with new Western designs.

Austrian objectors to nuclear power have made several arguments against Czechoslovakia's plans to expand its nuclear capacity. They point out that no one has studied the real cost of Czechoslovak energy or how much Czechoslovak industry could improve its energy-efficiency. According to Michael Undorf of the Austrian Greenpeace organization, the Austrian government has offered to form a joint commission to study this problem, and Moldan has tried to get the Czech government to accept, but without result.

Once Czechoslovakia carries out such studies, said Vienna University ecology professor Bernd Lötsch on Austrian television on 27 June, the Czechoslovak government will realize how much more effective it is to improve the efficiency and environmental standards of industry and existing power plants than to build new nuclear plants. Undorf agrees, saying "We hope that [the prohibitive cost of new plants] is what ultimately defeats the idea."

But conservation alone will not solve the Czechoslovak energy problem, according to Thomas Horacek, a researcher in an institute attached to the former Czechoslovak Energy Ministry. Czechoslovakia is a net importer of electricity from other Eastern European states, and more electricity will be needed relative to other forms of energy as the country modernizes its economy, he says.

Michael Schneider of the Paris-based World Information Service on Energy points out that schemes to finance new nuclear plants by exporting electricity have never worked in the past. Western nuclear power plant producers came close to realizing a deal with Turkey between 1983 and 1987. In exchange for a complete plant built by a Western company, Turkey was to have exported power for 15 years. But by 1987, both West German and Canadian companies had pulled out of the scheme.

If Italy does not in the end prove a willing customer, it is difficult to imagine there being any other market for electricity in another nearby country. Before German unification began, both West Germany and France were producing electricity surpluses, and by the time Czechoslovakia is in a position to build new plants, West German utilities are likely to have met the entire demand in what is now East Germany. Environmentalists have already vowed to fight if Austria moves towards approving the construction of power lines to Italy from Eastern Europe.

Steven Dickman

NUCLEAR CLEAN-UP

Runaway costs cause sharp reduction

Boston

Estimates of the cost of the first phase of the immense project to redress environmental damage occurring at US government facilities used to manufacture nuclear weapons have doubled in less than a year, according to projections released last week by the Department of Energy (DoE). The first five years of the 30-year clean-up are now calculated to require more than $28,000 million. The entire clean-up operation is expected to cost in the vicinity of $100,000–$200,000 million dollars over the next few decades.

DoE says that the projected costs are rising because of a better assessment of the job's technical requirements, and because of the increases in charges that are demanded by contractors to protect themselves against the lawsuits that may arise during the clean-up procedures. Provisions in current hazardous waste laws, as well as increases in environmental litigation by the states and the Environmental Protection Agency, conspire to make contractors increasingly wary, according to Leo Duffy, director of DoE's environmental management office.

Responses to the new cost estimates were mixed. While the Energy Department continues to win high marks for the *glasnost* fostered under Energy Secretary James Watkins' watch, critics complain that the department is absorbing the costs of cleaning-up into operating budget as a way to maintain personnel numbers even while facilities are being shut down (see *Nature* 342, 5; 1989). Some observers think that clean-up costs are likely to go higher still, so high that it may not be politically feasible to pay them.

Even if Congress does allocate the necessary funding, the current cost projections and the operation itself are predicated on the assumption that the Department of Energy will successfully complete its nuclear waste repositories in Nevada and New Mexico. But both of these facilities are far from completion and continue to be fraught with political opposition and technical problems.

Seth Shulman

Imaginary orderliness

SIR—The situation at the Natural History Museum (NHM) is as serious as any that has faced Britain's 'national' museums in recent times. Yet the bulk of Sir Walter Bodmer's Commentary (*Nature* **345**, 569; 1990) appears to ignore reality in a push for the status quo.

Professor John Evans, immediate past president of the Geologists Association, through his comments (reported by Henry Gee in *Nature* **345**, 99; 1990) on the corporate management proposals of the museum's director, Neil Chalmers, is working to advantage only the agenda of those intent on pursuing the narrow rational economic agenda. Statements such as "[the plan] has . . . been cobbled together in American-style business jargon presumably courtesy of Disneyland where many of the museum's administration went to learn such jargon" can surely be described only as ignorant nonsense.

The NHM is studying Disneyland so as to give visitors better service: that is good. Disneyland is expert at excellent customer services. That contributes more to the continuation of the NHM's outstanding work than abuse from single-interest groups who wish to brand everything about management as a fascist plot.

Evans' successor, Professor Beverly Halstead, long-time critic of changes at the museum in exhibitions which are based on very good research and sound judgement, has also done little to help the museum by his recent comments.

Detailed analysis of the corporate plan and of whether it is an appropriate response to the future is well worthwhile. But that exercise should surely use the same caution and logic as is applied by scientists to their own research.

The problem is the British government and its continued refusal to recognize the enormous importance of museums in *all* areas of science and education. And its failure to recognize their importance in economic terms is shown by recently published studies (for example, *The Economic Importance of the Arts* by John Myerscough, Policy Studies Institute, July 1988).

To help the museum and its staff and (most of all the public), the last thing one should do is to campaign on single-issue agendas such as taxonomy and the 'undesirability' of changing direction. I am astonished at the narrowness of view of many of the scientific groups expressing concern. Reading some of the draft letters that are circulating, one would imagine that the only problem resulting from reductions in the museum's funding was the loss of knowledge of sponges or crustaceans. Of course this is important, but it is the existence of the museum which is at risk. Only if that is secured will it be possible to discuss its shape and future programmes.

What would the Geologists Association do to reverse the trend at the museum towards salaries exceeding the total money granted by government? Presumably 132 years have taught them something. Try joining together with others concerned about the future of museums to put pressure on the government. It is a political issue after all.

DES GRIFFIN
(Chairman, Council of Australian Museum Directors)

Australian Museum,
6-8 College Street,
Sydney 2000, NSW,
Australia

SIR—Sir Walter Bodmer, writing as chairman of the trustees of the Natural History Museum (NHM), has defended the recent corporate plan of this museum[1]. He argues that, given a shortfall in funds, the scientific programme was the only area left in which cuts could be made. He points out that many scientific posts have been lost in the museum over the past five to seven years by random natural wastage and claims that, because of this randomness, "the director and his senior staff [have had to] assess research priorities" so that any further cuts would occur in a more orderly way.

Such orderliness is imaginary, however, for the imposed cuts do not fit any scientific plan. They were decided by heads of departments in obedience to the command: "Your department will lose *x* posts and you will decide which ones".

This command produced many anomalies where the redundancies run counter to the ostensible aims of the plan. To give one example out of many[2], the museum, under the plan, is supposed to be more environmentally aware than in the past — and we accept this aim. Nevertheless, research is to stop in diatoms, which are first-class environmental indicators of particular value in reconstructing the course of global warming. Many of these anomalies have been mentioned in parliament by Mr Tam Dalyell MP[3].

The brutality of the plan, the high-handedness with which it was announced, and other insults dealt to us by management, have demoralized the staff and produced many requests for voluntary retirement additional to those which the management originally called for. It is true that these requests are randomly distributed scientifically, but so are the cuts proposed by the plan. Allowing some requested retirements would provide several free posts and enough money to restore some of the axed curatorial and research positions. We therefore urge management to reassess the cuts with all this in mind.

After all, Sir Walter Bodmer would never claim that the museum is stronger without several axed scientists who dearly wish to stay, including a certain world-famous archaeozoologist and an internationally known palaeobotanist.

Journal titles

SIR—I commend Dr Judah Rosner's comments on the unseemly dogmatism of the AST (assertive sentence title). Perhaps he is right in suggesting that some scientists embrace this style in order to impress granting agencies. But there is one other factor. In 1981, Martin Glennie and I submitted to *Nature* an article with the fuddy-duddy title "The use of univalent antibodies to kill tumour cells". It was published as the resounding "Univalent antibodies kill tumour cells *in vitro* and *in vivo*". Had we in the intervening months become more thrusting and positive? Not in the least. The title was altered in the editorial office of *Nature*.

Southampton General Hospital,
Southampton SO9 4XY, UK

Eminent engineers

SIR—Not only was President Herbert Hoover an engineer (*Nature* **345**, 106; 1990), but he had strongly held views on the value of education. He wrote in 1941 that "British universities [had] refused to incorporate engineering into their curricula until much later than the Americans. In the meantime, the American engineers — especially the mining engineers — flooded the British Empire" (Foreword to T. T. Read's *The Development of Mineral Industry Education in the United States*, New York, 1941).

We would certainly be helped if Hoover's positive attitude to training engineers prevailed in British politics today.

Keele, Staffs ST5 5BG, UK

Opportunities for the East

SIR—Further to the News article "Opportunities for the East" (*Nature* **345**, 196; 1990), readers may be interested to know that the International Agency for Research on Cancer (WHO), based in Lyon, France, runs a fellowship programme for research training in cancer addressed to young postdoctoral scientists. This programme was initiated in 1966 and has already provided over 70 fellowships to Eastern European scientists, thus contributing to the maintenance of contact with the international scientific community and to the development of cancer research in the home country of the Fellows.

R. MONTESANO

International Agency for Research on Cancer,
150 Cours Albert-Thomas,
69372 Lyon Cedex 08, France

Hungarian freedom

SIR—Steven Dickman writes (*Nature* **344**, 615; 1990) that "The old Hungarian University became a Romanian one in 1920, when Transylvania was given to the Romanians as part of the peace of Trianon. But the Romanian faculty was forced to flee to Sibiu in 1940 when the Axis powers gave the area back to Hungary". He omits to say that the original Hungarian faculty was forced to 'flee' to Szeged in 1920. In 1940, the original Hungarian University of the city (Kolozsvar in Hungarian, Cluj in Romanian) was permitted to come back. After the Second World War, according to the agreement overseen by the victorious four powers of Britain, France, the Soviet Union and the United States, it was stipulated that Romanian and Hungarian universities should coexist. "Until 1959 Romanian and Hungarian universities existed side by side, then they merged into a predominantly Romanian entity", according to Dickman. This is not exactly what has happened. The truth is that the Hungarian faculty was suppressed on orders from Bucharest. An eminent professor at the Hungarian university committed suicide and in his farewell letter wrote that his act was a protest against the violation of liberty and the decree of suppression.

When the university was founded in the last quarter of the nineteenth century, more than 80 per cent of the inhabitants of the city were Hungarian. This is evident from the tombstones in the city's one cemetery. More than 80 per cent of those buried before 1920 were Hungarian. Many great Hungarian writers and musicians (Bartok and Ligeti, for example) were born in Transylvania.

We should also remember that the principle of the Austrian Empire was "*Divide et impera*" ("Divide and rule"). The Austrian emperor always listened favourably to the different ethnic groups of the empire.

Dickman states that there are now "30 per cent ethnic Hungarians, most of them housed in the huge blocks of flats characteristic of the Ceasescu era". He does not say that the Hungarians were expelled from their lodgings, which were then destroyed by bulldozers, and their former inhabitants were forced to live in "the huge ugly blocks".

Ceausescu was a terrorist who practised genocide and had a terrible hatred of Hungarians. It is this type of sentiment that caused the terrible tragedy in Tirgu Mures: the killing of unarmed Hungarian civilians, the wounding of more than 300 Hungarian civilians, the putting out of the eye of Suto, the well-known Hungarian writer, and other atrocities. Nothing similar occurred during more than 1,000 years of Hungarian rule.

The Hungarians of Transylvania are demanding only to be able to live freely without oppression and in harmony with the other ethnic groups.

New York, New York, 10003, USA

More on the Shroud

SIR—Regarding the procedure for obtaining samples from the Shroud of Turin for radiocarbon testing, M. S. Tite of the British Museum (*Nature* **332**, 482; 7 April 1988) says, "all stages will be fully documented by video film and photography". However, the official report of the test results (*Nature* **337**, 612; 1989) says: "All these operations, *except* for the wrapping of the samples in foil and their placing in containers, were fully documented by video film and photography" (my italics).

The key word here is "except"; its presence raises serious questions. Did the custodians of the Shroud agree that "all stages" of the procedure would "be fully documented" as Tite indicates in his letter of 7 April? If so, why did they make and suddenly break that reasonable agreement? (Note: The sampling of the Shroud took place on 21 April — just two weeks after Tite's reassuring letter appeared in *Nature*.) Why wasn't the entire procedure documented on video film and made available to the public? Without full documentation how can one be certain that it was the Shroud — and not another cloth — that was carbon dated? At what point in the sampling and sealing procedure did filming end — and why was it ended?

As Tite was the independent overseer of the carbon dating test and the guarantor of its unequivocal reliability, he has an obligation to address these unanswered questions. (That obligation would be very apparent had the Shroud been carbon dated to the first century.) And it should be noted that the man of the Shroud and the person(s) who imprinted his Christlike image are, as yet, unidentified — and not everyone is convinced that the Shroud is mediaeval as the results of carbon testing indicate.

TITE REPLIES—I confirm that, as stated in the *Nature* article, the wrapping of the samples in foil and their placing in containers was not documented by video. This was because we were continuing to follow the blind testing procedures according to which only the Cardinal, Professor Gonella and myself were to know which containers held the Shroud samples.

This aspect of the procedure was, I admit, somewhat illogical, as by this time we were aware that, because of the unusual weave of the Shroud, blind testing was not feasible without unravelling the samples. However, I should emphasize that it was the Cardinal and myself who were guarantors of the samples and that the video film was intended as an *aide-mémoire* rather than being meant to provide definitive proof of the identity of the samples.

HUGO's finances

SIR—We are, of course, delighted that the Howard Hughes Medical Institute (HHMI) has made a grant to HUGO of a substantial sum — $1 million over four years. However, your report (*Nature* **345**, 100; 1990) that this was HUGO's "first funding of note" is simply not true and we would like to set the record straight.

Earlier this year, you yourselves noted (*Nature* **334**, 5; 1990) that the Wellcome Trust (not Burroughs Wellcome) had made a three-year grant to HUGO, to cover the costs of its London office and its European activities. The Wellcome Trust's award is for approximately £175,000 in the first year (with another £50,000 available for programme activities yet to be defined) and will, overall, be of about the same order of magnitude as the HHMI grant.

Global leadership in semiconductors

Hajime Karatsu

Success in the semiconductor industry requires bold investment in new technology and total commitment to quality. US companies will never catch up with their Japanese counterparts until they learn these and other lessons.

WHAT is the secret of Japan's success in the semiconductor industry? In the early 1970s, the world market for semiconductor products was dominated by the United States. But by the 1980s Japan had taken over the key sectors of the market (see figure over) and now, for example, supplies about 80 per cent of the world's memory chips. If the United States is to compete once again, fundamental changes in the attitude of industry are needed, from the top levels of management down to the shop floor.

Technological progress

The key to the next generation semiconductor market is investment bold enough to keep up with the pace of technological progress. The success of Toshiba, which has won a large share of the market for 1-megabit DRAM (dynamic random access memory) chips, demonstrates how investing with vision can put a company ahead of the competition. Toshiba started heavy investment in its semiconductor division in 1984 and managed to supply the 1-megabit DRAM chips two years before its competitors. With this foothold, the company could sell at a profit while taking rapid depreciation on the advanced equipment needed for production, and thus was better positioned than the late starters. As the result of this foresight, Toshiba's semiconductor business reportedly accounted for half of its profits of $1.6 thousand million in 1989, even though the company is a highly diversified electronics giant with products ranging from locomotives to washing machines.

Today's fierce competition means that tomorrow's technology is being developed with ever-increasing speed. Adapting to this lightning pace requires aiming investment at the advances of the future. Toshiba's investment strategy was at least one year ahead of that of its competitors.

Shortening the time taken to develop new products is also critical. In the semiconductor industry, technological improvements are made in rapid succession, and introduced just as quickly to the shop floor. The old technology cannot match the new in cost and performance. Failure to adopt new technology will mean lost profits further down the road, and the longer the delay the greater the loss.

This may be why semiconductor firms in the United States have lost competitive ground to their foreign counterparts. A short-sighted focus on quarterly profits runs counter to the nature of the semiconductor business.

Commitment to quality

The term 'learning curve' is losing its significance in the semiconductor industry as a result of refinements in manufacturing technology during the past decade: we are now able to derive high yields from new chips in the first period of production.

One reason for this progress is the concept of 'super clean' technology, developed in Japan at Tohoku University. The concept is simple: it involves striving for perfect cleanliness at every stage of the production process. Gas and materials are pure; machinery, pipes, wells and lighting do not generate dust; and workers are free of contamination. Production yields have improved dramatically where this approach has been adopted.

Almost all materials and equipment used today, however, fall short of these standards. In the 5 February issue of *Business Week*, an article entitled "The Future of Silicon Valley" contained a photograph showing a cloakroom in a semiconductor factory and careless handling of workers' clothes. In Japan, workers' clothes are washed every time they are used. When I was at Matsushita Communication Industrial Co., workers making engine control units for automobiles were required to change their gloves every three hours to prevent dust from entering the most high-precision stage of the process. Thanks partly to this precaution, the defect rate was less than 0.1 per cent.

Manufacturing is by its nature a continuing battle against error and uncertainty. This is doubly true for the semiconductor business. Procured materials might not fit the specification exactly, skilled operators might get sick, machines can perform unevenly, designs may have to be changed slightly at the request of customers, and a microscope might reveal bacteria on a chip.

Some engineers tend to think about manufacturing flaws in terms of black or white, but the 'grey areas' can be important. Forcing distinctions may mean that the root of the problem is never reached.

At Matsushita, we received some defective products from a factory in Singapore that was affiliated to a US company. In one package, we found that contamination on the chips had corroded the aluminium pattern. When the factory manager visited Japan, I asked him to be more careful about his workers' clothing and masks and to review procedures for protecting against contamination. He replied that his men applied passivation covers to protect the chips from dust, so there must have been some other cause for the defect. The factory manager would not budge from his viewpoint. His attitude could be paraphrased as follows: "We tried as hard as possible. Why are the Japanese complaining about trifles?". I wonder what the response would have been if such defects had been found in a Japanese factory. Because dust is intrinsically harmful to semiconductors, all employees would have redoubled their efforts to prevent a recurrence, even if passivation covers had been applied.

Reaching a decision without exploring the middle ground, as the factory manager did, is not conducive to solving problems. This syndrome is exacerbated by confining employees to their specialized fields, where they are likely to develop a compartmentalized, self-serving attitude that may inhibit them from admitting their own mistakes. Attitudes such as that of the factory manager will not help to improve production efficiency and/or quality. Even if errors can be explained away, the product has the final word.

There are three ways to address the grey areas of manufacturing flaws. The first is to improve robustness against variation or error in production by selecting optimum parameters for materials, components and machine settings during design engineering. A new design methodology that has recently attracted attention is the Taguchi method, developed by Dr Genichi Taguchi of Bell Laboratories, for designing memory chips. It is gradually gaining favour in the United States and Japan. The second is to make the grey areas as small as possible by using 'super clean' technology. The third is aggressively to seek out sources of manufacturing errors that cannot be totally eliminated — that is, total quality control.

'Bottom up' strategy

Companies in Japan and the United States tend to have fundamentally different approaches to commercializing new technology. To borrow a metaphor from America's favourite pastime, US firms try to hit home runs, whereas Japanese companies try for single and squeeze plays. When carbon fibre was developed, for example, US engineers applied the technology to aviation, envisaging halving aircraft weight. But a new technology such as this tends to be accompanied by defects, requiring a long time for quality to be assured. So Japanese companies started using carbon fibre for making lightweight golf-club shafts and fishing rods, products in which defects were more easily corrected. Because of the mass market for these products, manufacturing volume increased rapidly, quality improved and costs declined. With this experience behind them, companies began applying carbon-fibre technology to aircraft. Today, the Japanese control 60 per cent of the global carbon-fibre market. I call this approach the 'bottom up' strategy.

The difference in approach to technology commercialization is also evident in LSIs (large-scale integrated circuits). Companies in the United States began by using them in sophisticated applications, such as airborne equipment, missiles and computers. Japanese companies, on the other hand, first used the chips in small calculators, leading to the development of pocket models. At the time, the cost of LSIs was too high for the consumer market, but Japanese engineers correctly perceived that it would decrease quickly as a result of widespread demand for more-compact calculators. When the models were first manufactured, an LSI chip cost $70; today, it costs only $1.

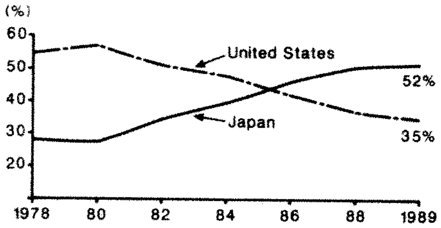
A critical factor in the development of pocket-sized calculator chips was CMOS (complementary metal-oxide semiconductor) technology. Japanese companies concentrated on this technology to lower the power consumption of calculators and wristwatches. This was the key to the development of random-access memory chips.

Another factor supporting Japanese companies' competitiveness involves the US–Japan semiconductor agreement, instigated by the United States. The anti-dumping provisions in the agreement drove market prices to double or triple. As Japanese semiconductor manufacturers also make computers, domestic appliances and electronic components, their electronics products were protected from price rises. Because intra-company shipments are not covered by the agreement, the parties harmed most by the sanctions were the US companies that depended on outside chip supplies. In effect, it was the goose that laid the golden egg, bringing in an enormous amount of money, which was in turn reinvested to further advanced semiconductor technology.

Defence market

Compared with the fierce consumer market, the defence market is rather sedate. At first sight, it would seem to be attractive because it demands the most advanced technology with less regard to cost, and the government guarantees the supplier's profit. When semiconductor technology was being developed, support from the US Department of Defense was important in making possible large investment for research and development. Some key technologies were developed as a result of support for defence projects.

But these merits conceal a pitfall for the semiconductor industry. Defence applications often do not keep up with the fast pace of technological progress. Once a chip is installed in a specific weapons system, the providers are requested to supply it for at least the next ten years. Any modification or improvement is not allowed in the name of standardization.



US and Japanese shares of the world semiconductor market (on the basis of sales).

In the civilian market, by contrast, companies jockey for competitive position by continually introducing improved technologies. Inferior products are forced out of the market. In Japan in 1989, 115 new facsimile models and 96 new copier models were released, attesting to the effects of stiff competition in the consumer and business markets.

It should also be borne in mind that production volume for consumer use is always greater than for defence use. Take, for example, the laser diode, a key component of compact-disc players. Hundreds of thousands of these diodes are manufactured every month in Japan. Technology developed for the mass market often has defence applications: CCDs (charge-coupled devices) for camcorders — produced in the same volume as laser diodes — are also used in the 'smart bomb', where they act as guides to the target.

In Japan, a stream of sophisticated new technologies superior to those created for defence use have been developed under the stimulus of free competition. The use of such advanced components is expanding the consumer market. In Japan, an auto-pilot model airplane equipped with a microprocessor and gyroscope costs about $300 in hobby shops, and robot toys are very popular with young people.

High-definition television (HDTV) is one of the hottest technologies of the next generation, even though work on it started more than 15 years ago at the research institute of the Japan Broadcasting Corporation. Since last year, one hour of test HDTV is broadcast every day by satellite. Meanwhile, Japanese manufacturers of domestic appliances are investing large sums to develop both new chips and display technology, including liquid-crystal flat displays (LCD). Japanese electronics companies began developing giant-size flat-screen display technology, for which their expenditure for constructing LCD factories is estimated at $10 thousand million last year. Wall-type TV screens should be on sale in Japan within five years. HDTV technology also has important defence applications, and is sure to be transferred to the military field — Japan has already supplied HDTV equipment to the United States for possible use in the strategic command room.

Attracting talent

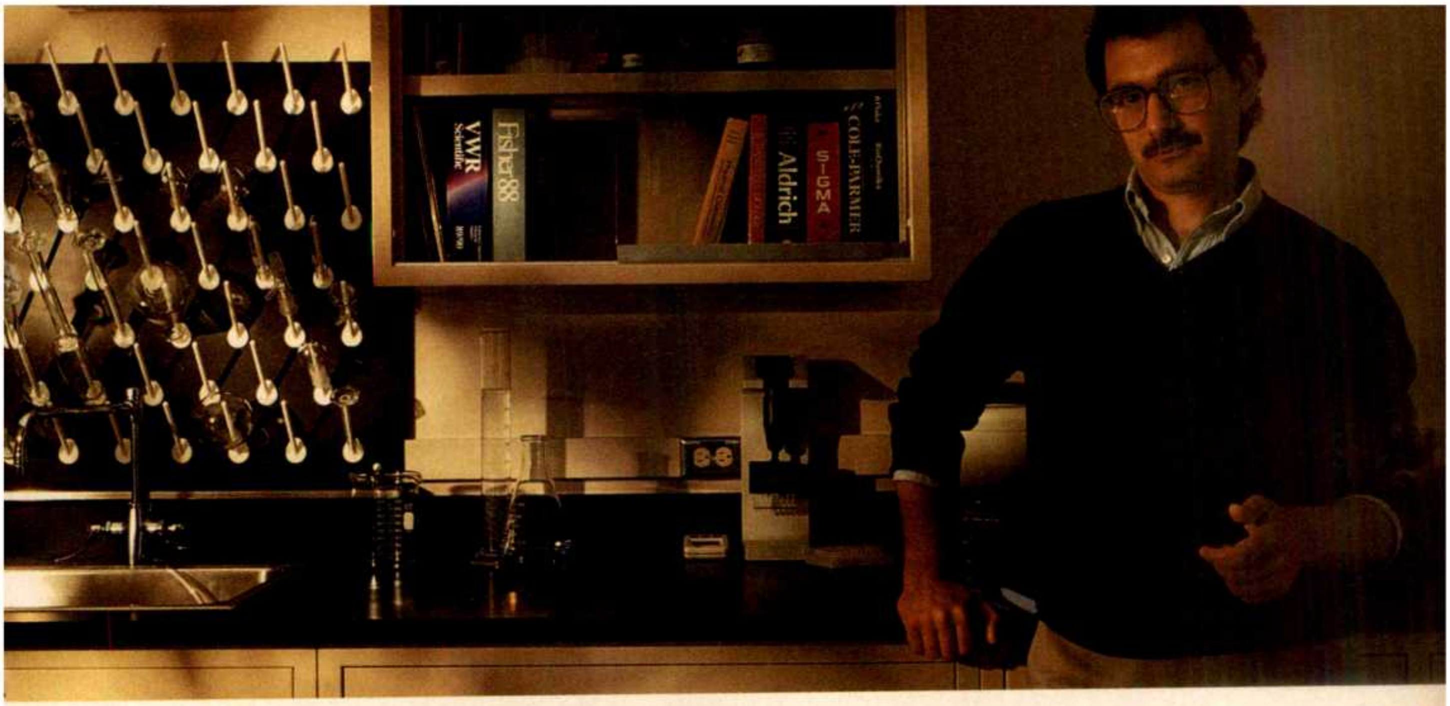
In 1987, I attended a conference in Finland at which a vice-president of McDonnell Douglas lectured on the next-generation transport aircraft. Through the introduction of such technologies as a nonducted-fan jet engine and a low-friction wing, he said, the aircraft will consume only about one-third the fuel of today's transports. These projects are sponsored by NASA.

As I listened to him speak, I imagined myself as a graduate of a US engineering school and asked myself if, with such exciting innovations in the aircraft industry, I would choose to work for the automobile industry, which is battered by overseas competition? I would opt for the aircraft industry, of course, and that is a cause for concern, because any industry that cannot attract talented engineers is heading for decline.

During a break, I asked the McDonnell Douglas executive about the size of the aircraft industry. He replied that it had $80 thousand million in annual sales. Sales in the US automobile industry total $270 thousand million. Given the strategic economic importance of the automobile industry, it has to attract the best engineers. The iron and steel industry lost much of its competitiveness because management, protected by quota systems, failed to adopt new technology. It thus became an undesirable sector for young engineers. The size of the steel industry is about $30 thousand million, just half that of the aircraft industry. The economic consequences would be much more severe if the automobile industry suffered the same fate.

I cannot stress too much the need to make those industries fundamental to a nation's economy attractive to young graduates. In Japan, we have been fortunate to have been successful in drawing many of the brightest graduates to work in them. But all industrial nations could do better in that respect, not least in the United States. ☐

Hajime Karatsu is in the Institute of Research and Development, Tokai University, Yoyogi, Tokyo, Japan.



I need synthetic peptides for my work.

But I don't have time to figure out the chemistry.
I just want to move ahead with my experiment.

All I know is, the Applied Biosystems Model 431A Peptide Synthesizer
gives me the right peptide on the first try, every time.

So I spend less time, less money on peptide synthesis.
Which means I have more time, more money to advance my research.

Call Applied Biosystems today for a free copy of
"Synthesizing Your First Peptide."

the simple solution:

Efficiency + Selection =

Altered Sites™

Mutagenesis system from Promega

Promega introduces a highly efficient *in vitro* mutagenesis system based on ampicillin selection for mutation. 80-90% linkages have been observed between a repair oligonucleotide which restores ampicillin resistance and a second mutagenic oligonucleotide corresponding to your insert.

- **High Mutation Efficiency:** Routinely 80-90% (control).
- **Strong Selection:** Antibiotic selection for mutation.
- **Versatile System:** Can be used to generate insertion, deletion, transition, and transversion mutation.
- **Ease-of-Use:** Single enzymatic step.
- **Controls:** System tested by "gain of function" mutation.
- **Versatile Vector:** The pSELECT™ mutagenesis vector offers:
  - Efficient synthesis of RNA *in vitro*—opposed SP6/T7 RNA polymerase promoters.
  - Production of single-stranded DNA—phage f1 origin of replication.
  - Expression of mutagenic protein—under control of *lac*Z promoter.
  - Direct sequencing of DNA inserts—SP6/T7 RNA polymerase promoter priming sites.

Stefan Marinov's seasonal puzzle

With yet another holiday season brewing up in the Northern Hemispehere, readers may wish to brood on a conundrum devised by an anti-relativist. No prizes are offered for a solution.

STEFAN Marinov, the exiled Bulgarian physicist now living in Graz in Austria, is himself a puzzle. He is indefatigable in the prosecution of what seems to be his only cause, which is to prove that Einstein's theory of relativity is a pack of lies.

Marinov claims, among other things, to have shown by direct measurement that the velocity of light differs according to the direction of its travel along a fixed path. He has also partly developed what he says is a perpetual motion machine, a kind of Wimshurst machine driven by an electric motor which, when last inspected at this journal's London office, was said to require a car battery for its operation.

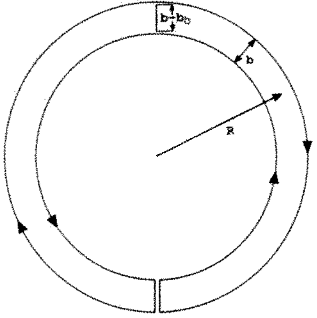
But most of Marinov's work is theoretical. Over the years, he has bombarded this and other journals with a series of papers with titles such as "The myths in physics" and "Violations of the laws of conservation of angular momentum and energy". Details of his correspondence with several editors may be found in his series of volumes called *The Thorny Way of Truth*, of which seven volumes have now been published by International Publishers (East–West) at Graz, of which Marinov appears to be the sole owner.

(From time to time, Marinov threatens to immolate himself in front of a British embassy or consulate if he cannot get an answer to a question about the publication of one of his papers. Some years ago, when embarked on such an enterprise outside the British consulate at Genoa, Marinov ran away when the police approached. Afterwards he explained that he had done so because he was in Italy illegally, without a visa. Mercifully, he has not threatened to immolate himself on *Nature*'s account for many months.)

Part of everybody's difficulty is that too little is said about the details of the experiments whose results are said to contradict common expectation for even sympathetic critics to be able to provide constructive statements of how they and Marinov part company. Another is that Marinov's single-minded zeal for his own conviction considerably outstrips the zeal of those who may disagree. But from time to time, in Marinov's copious writings, there are relatively simple arguments that appear accessible even to those still at high school. Here is one series of *gedanken* experiments presented as if it were a Christmas puzzle (the original intention), with some helpful (or misleading) hints for its solution.

The figure shows a pair of circular conductors arranged as two concentric circles. Equal electrical currents are circulated in each, but in opposite directions. The simplest way of creating this arrangement is to cut through the concentric pair at some point and to join the loose ends in pairs by short lengths of straight conductor. An electromotive force applied anywhere along the conductor will engender a current which must be everywhere uniform. At the bridged gap, there will be equal currents flowing in opposite directions, so their influence on the magnetic fields in the concentric gap will be zero.

The device is thus a means of arranging that there is a uniform magnetic field in the space between the concentric circles in a direction perpendicular to their plane (downwards into the plane of the paper when the current in the circuit flows in the direction indicated). The sensor in the experiment is a conductor long enough just to bridge the gap between the concentric circles and mounted on thin insulating supports in such a way that it can be made to slide around the circle. The objective is to measure the voltage across the sliding conductor, either by a standard voltmeter or by a condenser whose accumulated charge will be a measure of the voltage in a steady state.



The simplest case is when the sliding conductor is at rest. Then there is no voltage. Right? Next comes the case in which the sliding conductor moves at uniform speed around the concentric gap, always pointing along a radius of the concentric circles. As the slider moves, it will cut through magnetic lines of force at a constant rate, so there will be a constant voltage across the ends. The polarity of the slider will depend only on the direction of the current in the concentric circuit, and not on whether the slider moves clockwise or anticlockwise. Right again?

Now comes the tricky part, at least so far as Marinov is concerned. What happens if the sliding conductor is fixed in space, but the underlying concentric circuit is rotated about its centre? Relativity theory naturally predicts that the voltage across the sliding conductor would be the same as in the first experiment, and with the same polarity. On the other hand, questions may be raised about the degree to which the pattern of magnetic forces generated by the current is dragged around the ring by its rotation. Maybe there is a smaller voltage, but with the same polarity. What, asks Marinov, is the answer?

The second conundrum is superficially simpler: simply rotate the apparatus in its own plane, about the centre of the concentric circles. (There will be a small voltage due to the Earth's magnetic field, but this may safely be neglected.) Is there now a voltage, and with what polarity? If the answer to the first question is "Yes" the answer to the second must be "No", and vice versa. Readers are invited to make up their minds before reading on.

Marinov's own answers are unambiguous. Vice versa wins the day. When the underlying concentric circuit is rotated and the slider is kept fixed, there is no voltage across the movable conductor. But when the whole apparatus is rotated about its centre, the voltage across the now-moving sliding conductor is identical with that obtained when the slider is moving relative to the concentric circuit.

The implications are evidently important. The null answer to Marinov's first question implies that relativity has vanished through the window, the affirmative answer to the second implies that an isolated apparatus carrying a circulating current will generate a voltage when rotated, which raises forbidden questions about absolute space. Indeed, Marinov has devised a *gedanken* measurement of the Earth's velocity through space by stretching his concentric circuit into a linear version of it. He also claims that these violations of simple expectation are the basis on which his perpetual motion machine is built.

What is the truth? Nobody is quite sure, for nobody has done the experiments — not even Marinov. Indeed, one's confidence in the whole enterprise is somewhat undermined by Marinov's flat statement that he does not bother to repeat experiments whose outcome must be obvious. For one whose confidence in his own heterodoxy appears to be sustained only by his confidence that experiments will prove him right, Marinov seems curiously passive in the business. **John Maddox**

ECOLOGY

A chaotic synthesis

Rory Howlett

ECOLOGY has now emerged as an exact science[1]. This was the message of a recent meeting on the regulation and relative abundance of plant and animal populations*, an area where synthesis is not only possible, but probable (R. Southwood, Oxford University).

A growing trend in ecology is the analysis of long-term datasets to study the dynamics of populations either in isolation or when interacting with other species or variable environments. A common observation is that the apparent variability of population densities increases when calculated over longer periods of time[2]. Whereas plant populations have rather tame, often successional dynamics with recruitment depending upon the death of dominant plants (M. Crawley, Imperial College at Silwood Park), animal populations exhibit a vast array of dynamic behaviours, including periodic cycles and apparent chaos (I. Hanski, Helsinki University). Much attention is paid to the factors underlying population regulation, defined as long-term persistence and fluctuations within limits, the lower limit being greater than zero (see Murdoch and Walde in ref. 1). Comparisons within and between taxa show that species tend to have more constant populations when there is some dependence of *per capita* growth rate on population densities. But such density-dependence, although apparent in some long-term time-series, is generally difficult to detect, even when it is assumed to be operative. Moreover, as Hanski points out, local populations tend to be embedded in more broad-scale 'metapopulations' — dynamic entities in which local populations can become extinct only to be re-established later by dispersal — and this will critically affect their local dynamics.

The difficulties involved in detecting density-dependent regulation of animal populations were highlighted by Anne Keymer (Oxford University), whose group has been grappling with the ecology of human helminth infections. These parasites are generally highly aggregated among hosts and the overall populations tend to be temporally stable. Furthermore, interventions designed to control disease have resulted in large-scale population perturbations from which recovery is often rapid, suggesting strong regulation. But the actual density-dependent mechanisms are hard to pin down. They may arise from competition among parasites within hosts when at high density, or from acquired immunity of hosts after long exposure to parasites. Keymer argued that the latter mechanism appears, on present evidence, to be the more important.

Populations and communities are often very complex, but the very nature of this complexity can sometimes provide important insights into regulatory processes. As pointed out by Peter Chesson (Ohio State University), populations have internal structures that stabilize them and favour the co-existence of competing species. Spatial heterogeneity in the environment also affects population dynamics profoundly. This theme was expanded by Peter Kareiva (University of Washington), whose previous work on the dynamics of ladybirds and their aphid prey in fields of goldenrod has shown that the dispersal behaviour and demography of interacting species play crucial roles in determining the response of populations to mosaic environments (see ref. 3). In the case of host-parasitoid interactions, patchiness in the environment can be stabilizing (M. Hassell, Imperial College at Silwood Park; S. Pacala, University of Connecticut). Theory suggests that this effect comes from variation in the amount of parasitism from patch to patch. Parasitoid attack rates can vary between patches in ways that may or may not depend on host density, but the dynamical consequences of this variation are difficult to assess. But recent work shows[4] that the stability of host-parasitoid systems can be predicted using the simple rule: 'overall population densities will remain roughly steady from generation to generation if the coefficient of variation squared (CV^2) of the density of searching parasitoids in the vicinity of each host exceeds approximately unity'. When this criterion is applied to the real datasets and partitioned into density-dependent and -independent components, it suggests that, for 9 of 34 published studies, heterogeneity is large enough to stabilize dynamics and that density-independent heterogeneity is often the main stabilizing factor.

Science Photo Library

Tropical deforestation — ecologists are in a battle against time to understand the dynamics and diversity of the world's most complex and intractable ecosystems.

One of the most exciting areas of population ecology is the application of techniques developed to investigate the dynamical behaviour of complex systems (H.C.J. Godfray, Imperial College at Silwood Park; S.P. Blythe, University of Strathclyde). Recently, ideas have been developed for distinguishing measurement error from chaos in ecological time-series (G. Sugihara, Scripps Institution of Oceanography; see ref. 5); these have been successfully applied to data on measles, chickenpox and marine phytoplankton populations. But complexities arise when time series are subject to secular trends or darwinian evolution — an important consideration when analysing data such as those available for fish populations under heavy and sustained fishing pressure (J. Sheppard and D.H. Cushing, MAFF Directorate of Fisheries, Lowestoft). Indeed, the interplay of population dynamics and the evolutionary process is expected to influence population persistence (J. Travis, Florida State University), and even trends in biological diversity over geological time (J. Valentine, University of California, Santa Barbara).

Of all ecosystems, tropical forests must rank among the most complex. The challenge of understanding them has been taken up by S. Hubbell (Princeton University) and his colleagues, who have collected vast amounts of data on spatial patterns of sapling recruitment in a 50-hectare plot of a neotropical forest on Barro Colorado Island, Panama. They have used these data to study how tree species diversity is maintained. Strong negative conspecific effects on sapling recruitment in some of the densest species may prevent them from completely dominating the canopy, but many species do not show these effects, and Hubbell concludes that they may play only a limited role in determining the dynamics of a forest ecosystem. Studies of similar plots of forest located at sites right around the tropics, Hubbell hopes, will allow the development of a 'statistical mechanics' of complex communities.

---

* *Regulation and relative abundance of plant and animal populations*, The Royal Society, London, 23–24 May 1990.

Despite these advances, great gaps remain in our knowledge of even basic ecological facts, such as the total number of species on the planet (R.M. May, University of Oxford and Imperial College, London). Only through understanding the structure and regulation of communities can we hope to plan the conservation of life's diversity. ☐

OPTICAL ASTRONOMY

Are spiral galaxies opaque?

Michael Disney

ASTRONOMY is bedevilled by the presence of clouds of obscuring smoke mixed with the gas that drifts between the stars. This smoke (or dust, as it is more widely, but incorrectly, called) cuts off from sight much of the Universe and makes it difficult for us to interpret what we do see. On page 153 of this issue[1], Valentijn presents evidence that spiral galaxies are not, as has long been supposed, transparent, but are heavily clogged up with their own interstellar smoke. If he is right, rethinking of some major issues will be required.

If, as Valentijn suggests, we are seeing only the outer crusts of galaxies, we cannot so glibly assume that exotic 'dark matter' is necessary to explain the rotation curves of spiral galaxies (that is, their rotation seems to imply that more mass is present than is inferred from their optical radiation). At least in part, the hidden matter may instead simply be stars buried beneath the smoke. And the 'hidden starbursts' that have been invoked[2] to explain the surprisingly large infrared luminosities of spiral galaxies seen with the IRAS satellite may not be so widespread — the infrared could be merely starlight from obscured stars, reradiated by the cold smoke. We will also have to reassess the true proportion of galaxies undergoing nuclear activity, currently thought to be one or two per cent, as we may be seeing only the least obscured nuclei. If, furthermore, galaxies really are opaque, then as they pile up in the distance and fill our field of view, they will block out the more distant Universe at optical and ultraviolet wavelengths, cutting off high-redshift quasars and spoiling our view of galaxy formation.

The smoke in our own Galaxy strongly affects what we can see of it. On a moonless night the dark-adapted eye can see dark clouds of smoke outlined against the Milky Way. Optical radiation from the Galactic nucleus is attenuated by no less than 18 orders of magnitude. Fortunately, however, we live in the outer, relatively unobscured periphery of our Galaxy, so that if we look away from the plane of the Milky Way we get a fairly unobscured view of the extragalactic Universe. Astronomers in the majority of solar systems would not be so lucky, being forced to rely on longer-wavelength infrared and radio radiation to which smoke is more transparent.

When we observe another galaxy we have somehow to allow not only for obscuration along our line of sight but also the internal extinction within that galaxy itself due to its own smoke. How might this be done? In a highly influential paper in 1958, Erik Holmberg[3] suggested that we compare the properties of spiral galaxies tipped at different angles to our lines of sight. If they are perfectly transparent, their luminosities will be the same in all directions. But if they are perfectly opaque, they will look brighter when seen face-on, thus subtending the largest area of sky. Holmberg devised and carried out the classical test for opacity in spiral galaxies by comparing their apparent luminosities (or surface brightness) with their inclinations to the line of sight. From that test he and his successors concluded that spiral galaxies are largely transparent: when seen face-on, less than 40 per cent of their light is extinguished by internal obscuration[4].

Although simple in principle, Holmberg's test is very difficult to carry out in practice. How can one be certain, for example, that the edge-on galaxies in one's sample are drawn from the same intrinsic population as the face-on galaxies? One may not be comparing like with like. And even if such selection effects can be discounted, one cannot infer the extinctions from the observations without first adopting some more or less arbitrary form for the distribution of the smoke. If sunk in the galactic plane or gathered into compact clouds, it will obscure less than if it were widely dispersed. In any case, optical observations suffer from a systematic bias: more light will come from the least obscured parts of the galaxy, leading to a systematic underestimate of its extinction[5]. Most astronomers over the past 30 years have either ignored or discounted these difficulties and accepted Holmberg's view that spirals are largely transparent.

Such were the difficulties of observation in his day that Holmberg was forced to work with a sample of less than 200 galaxies. Taking advantage of the new automated and digitized microphotometers, Laubers and Valentijn[6] have measured at least 10,000 bright spirals appearing on the European Southern Observatory Survey plates. It is from this sample that Valentijn now draws his conclusions. With thousands rather than tens of galaxies to work with, he can be more selective in choosing his samples and, by comparing different samples, can make some esimate of his own selection effects. He compares the surface brightness of 2,500 spiral galaxies with their inclinations deduced from the ratio of their major to minor axes. Unlike Holmberg's, Valentijn's galaxies fit perfectly the totally opaque model, and are certainly inconsistent with the transparent or even semi-transparent models.

Valentijn's results clearly do not agree with Holmberg's or with Heidmann's[7]. Why this should be so is not clear. Valentijn believes that it is due partly to the greater selectivity that he can afford, and partly to the more precise definition and measurement of surface brightness afforded by his instrument. In one sense Valentijn's result is almost too good to be true, because it implies that even the outer parts of spiral galaxies are optically thick — a surprising result given the small amounts of gas detected there. To confirm the result requires mapping of spiral galaxies in the infrared, where they should be optically thin, and in the difficult sub-millimetre region, in which most of the cold ($\lesssim$ 20 K) dust should

show up in emission. Valentijn's result is more likely to stir up than to end the controversy.

If spiral galaxies are opaque, astronomers, and cosmologists in particular, will need to revise some of their ideas. Indeed, Davies[8] and Valentijn[1] have both now pointed to the difficulty of naively inferring the existence of missing mass from optical photometry (although they by no means discount the possibility of dark halos), and Wright[9] has demonstrated recently that the decline in quasar numbers at high redshift can be plausibly accounted for by the presence of opaque galaxies in the foreground. ☐

VISUAL NEUROSCIENCE

A causal chain in motion

Andrew Parker

EVER since microelectrodes reliably picked up action potentials from sensory nerve cells, there has been a continuing debate about the relationship between the firing patterns of cells and the perceptual consequences for the organism. In the early experiments, the emphasis was on simple detection of sensory stimulation[1–4]. This work produced some elegant and exciting conclusions. The retinal ganglion cells, whose axons communicate with the rest of the central nervous system, can detect flashes of light so weak that they contain only a few quanta of light[5,6]. The quality of sensation evoked by stimulation of single visual and tactile afferents may fall into discrete and readily identifiable perceptual classes[7,8]. As shown by Salzman, Britten and Newsome on page 174 of this issue[9], the same questions are being asked nowadays of regions of the brain that are more evidently concerned with higher-order perceptual analysis.

One suitable candidate region is the cortical visual area, V5 (or middle temporal, MT), whose function has been linked to the higher-order processing of visual motion[10–12]. Individual cells in this area are selectively excited by particular directions of visual motion. Last year, Newsome's group at Stanford showed that the sensory thresholds of single neurons in MT could match, or even exceed, the behavioural performance of the animal in a motion discrimination task[13]. Moreover, on occasions, there can be a reliable trial-by-trial association between the firing of single neurons and the behavioural response[14]. Now, with another clever shuffling of classical techniques, the same group[9] has studied the application to cortical neurons in MT of a weak, spatially localized, electrical stimulation at exactly the moment that a perceptual decision is required. Such a stimulation must slightly alter the firing patterns of MT cells and, as might be hoped, it can bias the perceptual decisions in a selective manner.

The experimental strategy relies on the functional organization of the properties of cells in MT. Not only is there a topographical map of the visual field onto this piece of cortex, but neurons with similar selectivities for the direction of motion are clustered together — probably in some form of columnar arrangement. Salzman *et al.* carefully determined the motion properties of a small region of MT by analysing the excitation of neurons in response to visual patterns of moving dots. Next, they presented a target of moving dots restricted to the same patch of the visual field over which the neurons could be excited. The dots could move either in the direction locally preferred by the neurons or in the opposite direction.

The animal had been trained previously to signal its judgement of perceived direction by shifting gaze from the initial fixation point to one of two locations either side of the target. In order to push the perceptual decision to threshold limits, only a fraction of dots in the target actually moved in the designated direction. The remainder moved in random directions and the measure of motion stimulus strength was the percentage of dots moving in a consistent direction. The critical result is that local electrical stimulation, applied at the same time as the motion target, may add to the nervous system's estimate of motion stimulus strength in a direction-specific manner. The authors present evidence that the electrical stimulation does not directly elicit the eye-movement response that is used as a monitor of the perceptual decision.

There are two surprising features of this work. The first is that electrical stimulation of a very small region of the cortex significantly affects a perceptual decision of the whole organism. Perhaps stimulation affects only a few cells at the stimulation site or perhaps it excites a particular neural circuit serving motion analysis, but the result does imply an extreme localization of function. Indeed, certain cortical locations in MT seem to be especially favourable for eliciting shifts in perceptual decisions.

On the other hand, the applied stimulation is rather nonspecific in its temporal aspects. Although it was confined to the duration of the visual stimulus, there was apparently no need to match accurately any naturally occurring temporal pattern of excitation for the cells. This gives little support to the notion that the exact temporal pattern of action potentials codes for the attributes of a stimulus. But this issue (and a number of related ones) can be resolved properly only when the experimental approach is modified to allow a more detailed analysis of the subjective qualities of sensation evoked by stimulation.

The information derived from this type of experiment should have at least one longer-term benefit. If the causal links between nervous activity and behaviour of the organism can be placed on a firmer basis, this knowledge will help to decide what kind of picture of brain activity is needed to assess neural function and dysfunction. The consequences for developments in brain-scanning techniques for use in clinical diagnosis could be profound.

It is an interesting comment on scientific fashion that 20–25 years ago the purist wing of artificial intelligence might have dismissed this kind of experiment as fatuous — after all, imagine trying to analyse the operation of a standard digital computer with a voltmeter, battery pack and a switch. Yet the brain clearly does not have a von Neumann architecture and has, through the course of evolution, generally adopted modular structures that have different functional properties, especially at a cortical level. Now the debate in parallel computing architectures is much concerned with structural organization and its consequences for computing efficiency, even at the hardware level. Although neural-network architectures are essentially parallel, their development has had separate motivations, often emphasizing the intrinsic value of distributed representations of information. How network systems can accommodate experimental results that imply highly localized and specific functional modules is somewhat problematic. ☐

PALAEOCLIMATE

Ups and downs of African lakes

Neil Roberts

WHEREAS Quaternary climatic change in high latitudes is dominated by the buildup and decay of ice sheets, the dominant climatic signal in low-latitude regions is not glaciation but precipitation. In areas such as inter-tropical Africa, arid and humid phases have alternated as the monsoonal circulation system has been weakened and strengthened. Tropical palaeoclimate is recorded most clearly by changes in the water level and chemistry of 'non-outlet' lakes. These had low water levels, indicating an arid climate, during and after the last glacial maximum (21–12.5 kyr ago), followed by a period of high lake levels (a humid climate) during the early part of the present interglacial (12.5 – 5 kyr ago). Unlike the slow responses of glaciation and vegetation to high-latitude climatic change, many low- and mid-latitude lakes respond rapidly to hydroclimatic change. On page 141 of this issue[1], Gasse *et al.* present high-resolution stratigraphic records spanning the period from 15 to 7 kyr ago from two such 'responsive' lake basins, one on each side of the Sahara. These two records show that, like the eustatic sea-level record of Northern Hemisphere deglaciation[2], the last arid-to-humid transition in Africa was not smooth, being broken by climatic events lasting 100 – 1,000 years.

Major climate changes driven by the Milankovitch cycle of the Earth's orbital variations are well established. Sub-Milankovitch climatic oscillations (known traditionally as stadials and interstadials) superimposed on these longer-term astronomically induced variations have also long been recognized, but they are currently becoming of increased palaeoenvironmental interest[3].

Their causes remain a subject of debate, but these almost certainly include agencies such as major emissions of volcanic dust and the formation of North Atlantic deep water[3,4]. Of these palaeoclimatic oscillations, the so-called Younger Dryas event (11–10 kyr ago) has received the greatest attention. Evidence now suggests that this event was felt well beyond its place of origin in northwest Europe, although its manifestation varied regionally across the globe[5,6].

In inter-tropical Africa, the period of the Younger Dryas is marked by sharp regressions in the water level of lakes such as Bosumtwi (Ghana, 6° N), Chad (13° N) and Ziway-Shala (Ethiopia, 8° N), indicating negative hydrological balances (a net deficit of water) and an arid climate[7]. These same lakes also record later regressional (arid) events of apparently similar magnitude and duration to the one contemporaneous with the Younger Dryas, for example between 8.0 and 7.2 kyr ago. This 7.5-kyr event is broadly coincident with, and may have been caused by, the collapse of the Laurentide ice sheet over Hudson's Bay. Although ^{14}C chronologies indicate that the hydro-climatic events centred on 10.2 and 7.5 kyr ago were synchronous between different lake basins in Africa, they have seemed until recently to be geographically restricted to sites in the inter-tropical zone. But the investigation by Gasse *et al.* of the more northerly Sebkha Mellala lake basin (Algeria, 32° N), and similar studies on the Tigalmamine basin (Morocco, 33° N) (refs 8 and 9, and H. Lamb *et al.*, unpublished work), now reveal that these short-lived regressional events occurred beyond as well as within the tropics. The interruptions to the hydrological cycle at around 10.2 and 7.5 kyr ago are thus apparently of continental or even of global significance.

H. F. Lamb

Lake Tigalmamine, in the Middle Atlas mountains of Morocco. Pollen and diatom analyses of sediment cores[8,9] from this lake show evidence of abrupt short-term falls in lake level which occurred at times similar to those known from sites in tropical Africa.

One intriguing question, on which the jury is still out, is whether sub-Milankovitch climatic events have occurred throughout the recent geological past or whether they were restricted to times of major climatic transition, such as the end of the last glaciation. Abrupt lake-level oscillations are not equally 'visible' throughout the late Quaternary record: regressional events, for example, are stratigraphically much more evident at times of high rather than low lake levels. The record of the late Holocene (in any case a period of low lake levels in Africa) is complicated further by increasing human influence and the difficulty of disentangling natural from cultural factors. Nonetheless, data are beginning to emerge which suggest that tropical climatic 'crises' occurred not simply over recent millennia but even in recent centuries. One especially startling piece of evidence comes from cores taken in Lake Malawi, which reveal that the level of this great lake fell by about 100 m at some stage within the past thousand years, signifying a reduction in rainfall at that time to 50–70 per cent of modern values[10].

To understand the climatic mechanisms responsible for these hydro-climatic events, there is a need to establish as precisely as possible their spatial extent, age, duration and intensity. As Gasse *et al.* have shown, non-outlet lakes in regions such as Africa and the western United States look set to provide the best source of answers to such questions. It is clear that, unlike the Milankovitch changes brought about by variations in the solar radiation received by the Earth, these events cannot easily be predicted, thereby creating considerable uncertainty for projections of future climate. ☐

NEUROBIOLOGY

One neuron, many units?

Larry Cohen and Jian-young Wu

Is the neuron the functional unit of the nervous system or can small portions of a neuron act as independent units? Neurobiologists have been speculating about this second possibility for more than 30 years[1,2], partly because microelectrode recordings from cerebellar Purkinje neurons reveal small spike signals that are almost certainly all-or-nothing events occurring in restricted areas of the dendritic tree[3,4]. Bill Ross, Nechama Lasser-Ross and Bob Werman[5] have now determined the spatial distribution of such events by using multi-site optical recordings with a calcium indicator dye. The findings are important because they show that one can now directly measure the independent activation of parts of a neuron.

One of the results obtained by Ross *et al.* is represented in Fig. 1, which shows a high-time-resolution recording from a Purkinje cell in a slice from guinea-pig cerebellum. Three dendritic regions can be differentiated: a region on the lower left where both of the small spike signals are detected as rapid increases in calcium; regions on the upper left and lower right where only the second of these signals is detected; and regions where neither signal is detected. In one especially complex cell, the authors were able to resolve six different compartments.

Because the dendrites of the cerebellar Purkinje cell are postsynaptic only, the effects of independent activation of the dendritic elements would be integrated at the spike-initiating zone, thereby determining the cell's output. This kind of organization is not, however, universal. Other neurons have both output and input synapses in the dendritic tree[6]. If a dendrite of such a neuron were independently activated, it would form a complete functional unit. It is possible, for example, that dendrites function independently in certain horizontal cells and starburst amacrine cells of the retina, and in nonspiking interneurons in the locust. Calculations suggest that the dendritic trees of these neurons can be divided into several electrically distant regions[7-10], and electron micrographs show that the independent regions both receive and make synaptic contacts. Furthermore, for both the horizontal cell[7] and locust interneuron[11] there is physiological evidence that is consistent with the existence of independent units, but this has not so far been directly demonstrated. Such a demonstration might best be achieved by measuring the membrane potential at many sites using a voltage-sensitive dye on the inside of the neuron: changes in membrane potential may be interpreted more easily than changes in calcium concentration. Unfortunately, however, the signals from voltage-sensitive dyes applied to the inside of neurons have so far been relatively small[12,13].

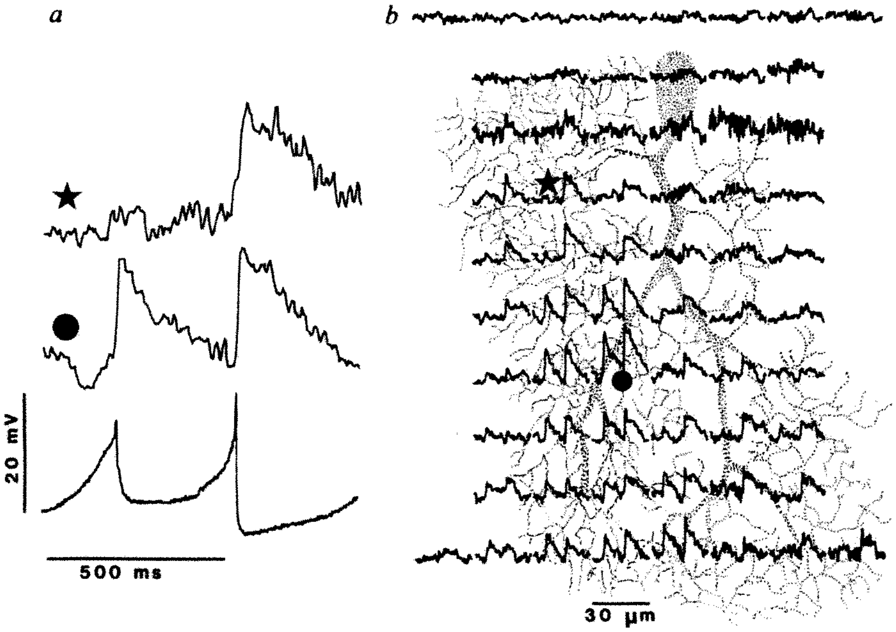

FIG. 1 Optical and microelectrode recordings from a Purkinje cell that has been microinjected with Arsenazo III in a 200-μm slice from guinea-pig cerebellum. *a*, The microelectrode recording from the soma (bottom trace) shows two small spontaneous spikes which differ in size. Optical recordings from detectors receiving light from two different areas of the dendritic tree are shown above the recording. In the top recording only the second spike event is detected, whereas in the middle trace both spike events are seen. *b*, Outputs of 64 photodiodes receiving light from 64 areas (each 30 × 30 μm square) of the slice overlaid on a drawing of the neuron. The cell body is at the top; the axon (not shown) leaves the cell body at the top of the figure. (Modified from ref. 5.)

It is difficult to predict how widespread independently acting dendritic units might be; there are neurons in which independent activity seems unlikely. For example, signals initiated anywhere in the electrically compact dendritic tree of an insect neuron can be detected equally in the cell body[14]. And in some crustacean neurons it has been impossible to detect compartmentalization of the calcium signal[15].

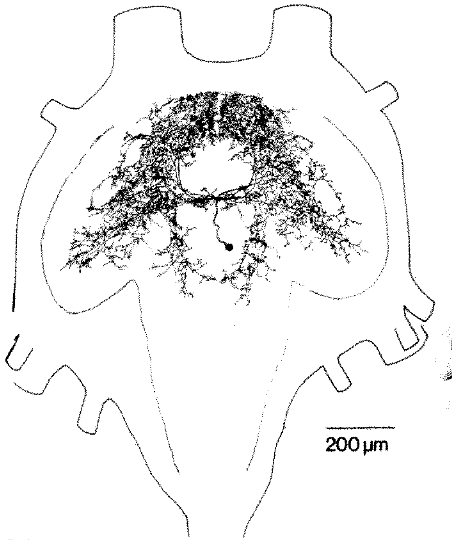

FIG. 2 Structure of a small dorsal unpaired median (DUM) spiking interneuron from a grasshopper ventral ganglion. The cell was stained with cobalt–silver and drawn from a whole mount. (Modified from ref. 19, courtesy of Karen Thompson and Melody Siegler.)

Although the prospect of directly measuring independently functioning regions of the dendritic tree is exciting for cellular neurobiologists, the existence of such regions would pose a problem for those trying to understand how behaviours are generated from neuronal interactions. Monitoring the activity of independent units in a dendritic tree is much more difficult than simply keeping track of the membrane potential of the cell body.

This would not be the first instance where an important discovery in cellular neurobiology increased the difficulty of understanding how behaviours are generated. Another was the demonstration that some neurons do not generate action potentials; these nonspiking neurons maintain their resting potentials in the middle of the range of potentials leading to transmitter release[2,6,16]. A problem in monitoring the activity of a nonspiking neuron is that the membrane potential measured at one location in the cell might not be an accurate representation of the potential at other locations in the cell.

Although nonspiking neurons are widespread in the animal kingdom[2], there are nervous systems in which such cells are relatively rare. Even though nonspiking neurons are found in gastropod molluscs[17,18], the best guess is that less than one per cent of the central neurons in *Aplysia* are nonspiking. Furthermore, nonspiking synaptic interactions are also rare in *Aplysia*.

A third instance of a double-edged success for cellular neurobiology is provided by the complex structure of neurons seen under the microscope. One beautifully ornate example is the interneuron from a grasshopper ventral ganglion illustrated in Fig. 2. The extent of the dendritic tree implies that the neuron may be in synaptic contact with a large number of other neurons in the ganglion. Obviously, a nervous system in which each neuron interacts with many neurons is more difficult to analyse than one in which synaptic interactions are restricted.

Widespread synaptic interactions may be the rule rather than the exception. For example, serial-section electron microscopy indicates that a mechanosensory cell in the leech makes about 2,500 anatomical synapses onto postsynaptic neurons[20] (K. Muller, personal communication); it would be interesting to know the distribution of the 2,500 synapses among the 390 neurons in the ganglion. In the nematode *Caenorhabditis elegans*, the ADE-L sensory neuron is monosynaptically connected to 9 per cent of all other neurons in the animal and disynaptically connected to an additional 52 per cent. Only slightly lower percentages are obtained starting with sensory neurons OLL-L and PHC-L (compiled from ref. 21). Finally, in *Aplysia*, 300–400 of the 1,000 or so neurons in the abdominal ganglion are activated by lightly touching the siphon skin[22,23]. It seems that information about sensory stimuli is propagated widely in these nervous systems. This raises the possibility that the organization of the response to the stimulus may also involve many neurons[24].

It will be exciting to see what roles these complex cellular properties have in the generation of behaviours. Using the techniques of Ross *et al.*, the existence of independent functional units in a neuron can now be directly studied. It will be a challenge to systems neurobiologists to develop methods for handling the potential complexity of widely interconnected neurons. But, surely, the question of how behaviours are generated from interactions of neuronal elements is the central concern of neurobiology. ☐

EVOLUTIONARY EPIDEMIOLOGY

Parasite clones in the wild

Anne E. Keymer, Robert M. May and Paul H. Harvey

SEVERAL species of parasitic protozoa will reproduce sexually in the laboratory[1-3]. That sexuality is an advantage in such cases is indicated by an excess of recombinants being produced from mixed-genotype infections[4]. It does not follow, however, that sexuality is important in the wild just because it can occur and have advantages in the laboratory. Indeed, preliminary field observations of several species (including the protozoa that cause leishmaniasis and Chagas disease) have indicated clonal population structures that are stable for many generations and over wide geographical areas[5,6]. Until recently it could be assumed that the laboratory and field studies had looked at different species or different strains of a species, and that sexual reproduction differed in frequency between the two groups. But a new report by Tibayrenc and colleagues in *Proceedings of the National Academy of Sciences*[7] casts doubt on this interpretation: species which may be sexual in the laboratory have a clonal population structure in the wild. The finding may have important implications for biological control programmes.

Using data from species belonging to seven genera of parasites, Tibayrenc *et al.* propose that clonal population structures are the norm in natural populations. In each genus (*Entamoeba, Giardia, Leishmania, Naegleria, Plasmodium, Trichomonas, Trypanosoma*) there are fewer genotypes than would be expected if regular outbreeding occurred. In their analyses of biochemical variability, the authors used seven criteria when testing for clonality. Three are based on tests of the significance of observed levels of segregation and are applicable only to diploid organisms: fixed heterozygosity, the absence of segregation genotypes, and deviation from the expectations of a simple Hardy–Weinberg equilibrium model. The other four criteria are tests of the significance of observed levels of recombination and are thus independent of ploidy: widespread existence of identical genotypes, absence of recombinant genotypes, linkage disequilibrium, and correlations between independent sets of genetic markers. The results imply that naturally occurring populations derive from the clonal reproduction of a few highly successful genotypes, as highlighted by the predominance of particular clones in different localities, sometimes in different host species, and at intervals separated by many years.

A few examples illustrate the new findings. The *Leishmania* zymodeme (a genotype determined by electrophoretically distinguished enzyme patterns) MON 1 is predominant in both the Old World and in Latin America. A clone of *Plasmodium falciparum* (Gpi1/Ada1/Ldh1/Pep1) has been isolated from ten out of 17 samples in five countries spanning Africa and Indochina. *Entamoeba histolytica* zymodemes I, II and III have been sampled repeatedly in Canada and South Africa. Six identical strains of *Trichomonas vaginalis* have been identified: five that were isolated recently, and one in 1939. And a single zymodeme of *Giardia* has been found in five human hosts and two cats (one in Western Australia and the other in Oregon).

The results imply that clonality should be adopted as the working hypothesis by those involved in research on diseases caused by the parasitic protozoa. Genetic

recombination is not ruled out — the data simply show that it does not significantly affect the prevailing patterns of clonal population structure. What, then, of the sexuality so clearly demonstrated in the laboratory? Are recombinants selected against in the wild?

More ambitiously, can these systems provide us with precise, quantitative insights into evolutionary problems such as the generation of stable or shifting polymorphisms by frequency-dependent selection, or the origins and maintenance of sexual reproduction[8,9]? To answer these questions, we need to know more about the epidemiology of individual clones, the frequency of multiple-clone infection, and the mechanisms and consequences of clonal competition. Increased integration of work in the field and in the laboratory will help, as will further cooperation between geneticists and epidemiologists. ☐

SUPERCONDUCTIVITY

Bringing about some order

Robert J. Cava

It seems fitting that $YBa_2Cu_3O_7$, the first material found to be superconducting above liquid-nitrogen temperature, exhibits one of the most interesting and complex interplays between chemistry, crystal structure and physical properties of any ceramic material studied so far. At the heart of the matter is a subtle charge balance between the one-dimensional copper–oxygen chains, which have variable oxygen content, and the two-dimensional copper–oxygen pyramidal planes, where superconductivity originates (see figure). The latest surprise is described in an elegant paper by Jorgensen *et al.*[1], who find a correlation between the appearance of superconductivity in an originally nonsuperconducting oxygen-deficient sample, after annealing at room temperature, and time-dependent changes in its crystal structure. As well as demonstrating that the oxygen atoms are mobile at ambient temperature, the results show more importantly that the superconducting properties are remarkably dependent on local, short-range structure. This situation is likely to be unique to the high-transition-temperature copper oxides, in which the coherence lengths of the superconducting charge carriers are of the order of the size of the crystallographic unit cell.

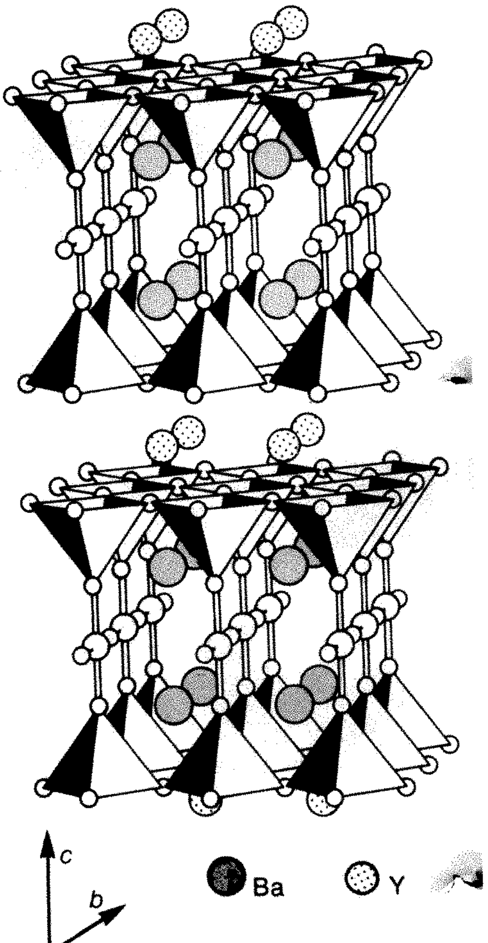
In oxygen-deficient $YBa_2Cu_3O_{7-x}$, oxygen is removed from the Cu–O chains: a 90-K superconductor is obtained for $0 \leq x \leq 0.2$, a 60-K superconductor for $0.3 \leq x \leq 0.55$, and an antiferromagnetic insulator for $0.55 \leq x \leq 1.0$. These changes can be shown to correspond to a series of charge transfers from the chains to the pyramidal planes[2]. In $YBa_2Cu_3O_7$, the Cu–O chains are aligned along one crystallographic axis (the orthorhombic *b* axis), while an equivalent direction in which they could lie — the *a* axis, perpendicular to the *b* axis — remains unoccupied (thus the *a* axis is shorter, as the chain oxygens are missing; see figure). As oxygen is removed, the chains become fragmented; eventually the fragments become short enough to be able to align along either the *a* or the *b* axes. These axes then become equivalent, making the overall symmetry tetragonal even though on the scale of the length of the chain fragments the symmetry is still orthorhombic. The orthorhombic-to-tetragonal phase transition is a function of both the total oxygen content and the temperature, because the orientational disordering of the chain fragments increases the entropy of the system.

The paper by Jorgensen *et al.* follows up their initial discovery[3] of time-dependent superconducting phenomena in $YBa_2Cu_3O_{7-x}$. The present results were obtained from polycrystalline samples prepared at the composition $YBa_2Cu_3O_{6.41}$ by annealing $YBa_2Cu_3O_7$ for a long period at 520 °C at reduced oxygen pressure and then quenching into liquid nitrogen. At the preparation temperature and oxygen content, the compound is tetragonal with disordered chain fragments. The quenching is performed to maintain the sample as much as possible in the high-temperature disordered state, which should not be stable with respect to lower-entropy states at room temperature. But the orthorhombic symmetry observed for the samples immediately after quenching indicates that even at a rapid quench rate the oxygen atoms have time to partially rearrange from the disordered structure.

One of the clever aspects of these experiments is that Jorgensen *et al.* pick an oxygen content right at the superconducting/nonsuperconducting boundary. The sample is initially nonsuperconducting, but soon develops a superconducting transition with a transition temperature that saturates at 20 K after about 72 hours. This temperature is significantly lower than the 55–60 K observed for 'equilibrium' samples at a composition near $YBaCa_2Cu_3O_{6.50-6.45}$ (which corresponds to the minimum oxygen content generally required for superconductivity).

In a demonstration of one of the great assets of the neutron time-of-light powder-diffraction technique, the authors have made full crystal-structure determinations at 27 stages during the first 26 hours of the ambient-temperature annealing. The structural changes involve the shortening of all the crystallographic axes, with the greatest shrinkage along the *a* axis, and also a shortening of the bond between the pyramidal copper and its apical oxygen. Surprisingly there is no change (within the precision of the measurements) in the amount of oxygen in the chain sites on the *a* axis relative to the those on the *b* axis, implying that there is no large-scale lengthening or increase in the number of chain fragments aligned along *b* at the expense of those along *a*. In addition, there is no change in the total oxygen content.

The authors estimate the length scale of the diffusion process that gives rise to these structural and physical changes to be 4 Å — approximately the size of a unit cell. The appearance of superconductivity, therefore, is due to the short-range



The structure of $YBa_2Cu_3O_7$, showing the one-dimensional Cu–O chains and the two-dimensional Cu–O pyramidal planes. Crystallographic *a*, *b* and *c* axes are also shown.

rearrangement of oxygen atoms in the chains, giving rise to charge transfer to the planes as is evidenced by the decrease in the distance between the plane copper atoms and the apical oxygen. Because of the very short coherence lengths of the superconducting charge carriers, superconductivity is observed even when only microscopic regions of the crystallites have the appropriate oxygen configuration. The relatively low transition temperature may be due to the proximity of superconducting and nonsuperconducting regions. It is not easy to understand, without more data, exactly how a microscopic rearrangement of oxygen atoms can produce no change in the overall ratio of the *a*- to *b*-orientated chain fragments while disproportionately decreasing the *a*-axis length. Perhaps, as Jorgensen *et al.* suggest, it involves the formation of alternating, parallel full-chain/empty-chain fragments on a local scale, as are found on a longer scale for the 60-K superconductor $YBa_2Cu_3O_{6.5}$. But whatever the case, whereas some might argue that there can no longer be anything new or exciting to learn about $YBa_2Cu_3O_7$, Jorgensen *et al.* have clearly shown otherwise. ☐

OCEAN DRILLING PROGRAM

Reading the ocean's diary

Leg 130 shipboard scientific party

How does sedimentation respond to changes in global climate and ocean dynamics? And what is the origin of the world's largest oceanic plateau? It was to address these questions that Leg 130 of the Ocean Drilling Program took the RV *JOIDES Resolution* to the Ontong Java Plateau in the western equatorial Pacific. This plateau is ideally suited to such studies, being a flat, shallow region of sea floor — the result of an unusually thick (40-km) oceanic crust and a thick (1,400-m) sediment cover. Being free of interference from coastal ocean processes, the region has the potential to provide a complete, undisturbed record of open-ocean pelagic sedimentation since the middle Cretaceous (about 100 million years ago). The cores recovered by Leg 130 succeeded not only in illuminating this history, but also in supplying clues to the origin of the plateau itself.

The Ontong Java Plateau (Fig. 1) has drawn the interest of marine geologists since the beginnings of deep-sea drilling[1–3], and has provided standard sedimentary sections for the evaluation of Pleistocene palaeoceanography[4,5]. Two boreholes drilled during Leg 130 penetrated through the sediment cover into the basalt basement below (one to a depth of 26 m and the other to 149 m into the basalt), opening the way for petrological studies of the origin of the plateau and for palaeomagnetic studies of its movement since the middle Cretaceous. The basements of oceanic plateaus in the Pacific have been penetrated only four times by previous drilling projects, and never before to such depth. The Leg 130 results show that the Ontong Java Plateau is oceanic in origin, having been formed at depths of 2,500–3,000 m during the early Cretaceous from flood basalts and flows of basaltic pillow lavas. One of the significant aspects of oceanic plateaus (of which the Ontong Java is the largest, being one quarter of the size of Australia) concerns their possible role in the growth of continents[6]. Palaeomagnetic data will provide an important means of tracing their movements throughout past epochs, as all of the drill sites on the Ontong Java Plateau reached their present equatorial locations only relatively recently (during the late Neogene — the past 5 million years). Massive outpourings of basalt during the early Cretaceous, of the sort that now seem to have formed the Ontong Java, have been postulated before[7]. They would have caused changes in global sea level and — if occurring over a sufficiently short time interval — also in oceanic circulation and chemistry.

But the principal palaeoceanographic questions addressed during this leg concerned the response of the ocean — specifically the biogenic sedimentation therein — to changes in the variation of mean temperatures across the planet. It is known that during the Neogene, the temperature gradient between the equator and the poles increased as a result of expanding snow and ice fields in polar regions. This trend resulted from thermal isolation of the Arctic Ocean and the Antarctic continent (through continental drift) and from overall sea-level regression. Regression is the consequence of mountain building, which thickens continental crust and deepens the ocean basins; it exposes land surfaces, which reflect more sunlight than the sea, and thus increases the planetary albedo.

The way that the global oceans responded to this increasing temperature gradient would have been mediated by the major changes in geography that were taking place at that time — the opening of the Drake Passage between South America and Antarctica, the intermittent build-up of the Antarctic ice cap, the closing of the Tethys seaway (which once connected the Atlantic and the Pacific from the Mediterranean region to the Himalayas), the rise of the Himalayan mountains and the separation of the Pacific from the Atlantic by the Isthmus of Panama. The combination of this evolving geographic setting and the increasing latitudinal temperature gradient would result in an episodic reorganization of established patterns of heat flow and ocean productivity, and thus in episodic changes in plankton distributions and in sedimentation of biogenic matter.

The Leg 130 sediment cores gave insight into these complex processes. The sedimentation-rate profiles for each site (Fig. 2*a*) show that the overall sedimentation rate for the past 25 million years is dominated by a low in the late early to early middle Miocene (20 to 15 Myr ago) and a prominent peak in the late Miocene to the earliest Pliocene. The crossing of the equator by some sites (indicated by squares in Fig. 2*a*) had no or little influence on these trends. At sites 803 and 804, the periods of low sedimentation rate are characterized by hiatuses (denoting levels where sediment is missing), suggesting sporadic sediment removal by erosion or mass movement[8]; but sites 805–807 seem to be biostratigraphically complete. The onset of the low-rate period coincides with a marked change in the carbon

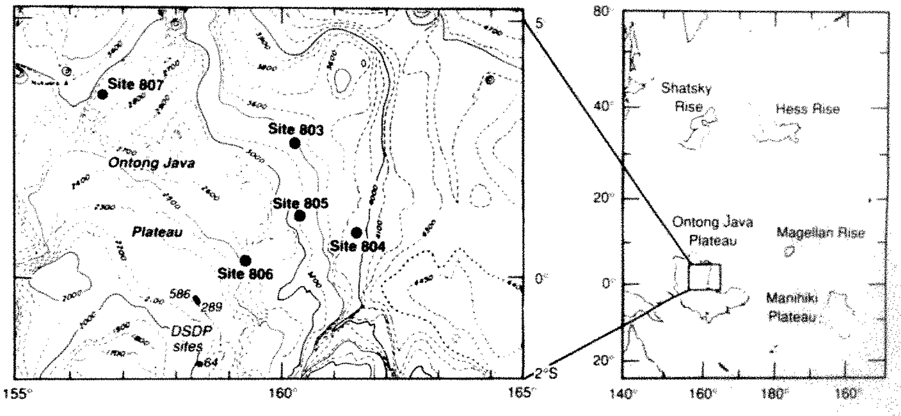

FIG. 1 Location map of Leg 130 sites. Bathymetry is in metres.

isotope composition of the ocean[9], which is the result of an increased difference in productivity between the deep sea and coastal waters. Increased coastal productivity captures a greater share of nutrients for the margins, with the result that sedimentation in the deep sea is decreased.

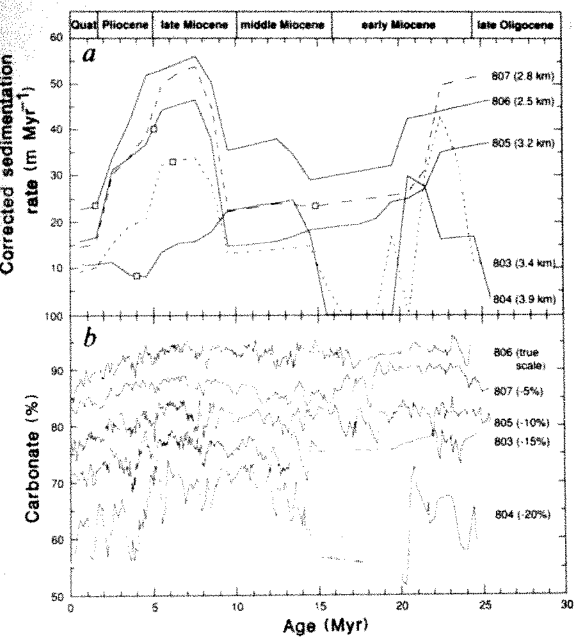

FIG. 2 *a*, Sedimentation rates (corrected for compaction) as a function of age for Leg 130 sites 803–807. Water depth for each site is indicated on the far right-hand side. Squares indicate the times when the sites crossed the equator. *b*, Carbonate percentages as a function of age for Leg 130 sites 803–807. Note that the absolute carbonate values for the sites have been adjusted by 5–20 per cent (see right-hand side of figure) to facilitate comparison. Acoustic reflectors in the seismic profiles often coincide with sharp changes in carbonate content.

The period of high sedimentation rate, centred around 7 Myr, in fact displays some of the highest rates (about 50 m Myr^{-1}) ever recorded in open-ocean pelagic sediments. The timing of this period suggests that these high rates may be associated with the closing of the Tethys and with important phases of mountain-building, leading to an increased supply to the ocean of continent-derived materials. At this time, a pronounced gradient of productivity developed from east to west in the equatorial Pacific[10,11]. Eventually the piling up of warm water in the western Pacific, owing to increased trade winds, led to a reduction of productivity. The high sedimentation rates fell off during the Pliocene and especially during the Quaternary, accompanied by decreasing preservation of diatoms and radiolarians in the sediments. This drop also may be the result of removal of nutrients and silica along the coastal oceans by increased coastal upwelling. This finding is puzzling because we must assume that strong trade winds continued to drive upwelling in equatorial regions, and yet the sedimentation rate dropped at the sites drilled.

Since the middle Miocene, sedimentation rates at all the sites have been similar. The amounts of carbonate deposited (Fig. 2*b*) are also highly correlated between sites for the past 12 million years, but poorly correlated before this. These observations suggest that a strong vertical gradient of carbonate saturation, which controls the increase of dissolution of carbonate with depth, became established at this time as a result of increased cold deep water formation. But it is puzzling that the carbonate values of deep sites are so similar to those of shallow sites. Carbonate removal by dissolution cannot by itself explain simultaneously the (distinct) differences in sedimentation-rate patterns between the sites, and the (slight) differences in carbonate content. More will be learned on this point by improving the resolution of sedimentation rates through analyses of Milankovitch frequencies in the record, of physical properties and of stable isotopes.

An important objective of Leg 130 was to account for the strong acoustic reflectors that give a 'layer-cake' appearance to seismic profiles of the sediments. Many of these reflectors correspond to the sharp changes in carbonate content seen in Fig. 2*b*, and there is some correlation between sites. On the whole, the results support the proposition that at least some of the major reflectors are caused by palaeoceanographic events (such as dissolution pulses) that affect carbonate deposition[12,13]. ☐

DAEDALUS

Animal warmth

Animal fur and feathers are wonderfully self-adjusting. An animal or bird can fluff up its coat in cold weather for extra insulation, or smooth it down in the warm to dissipate heat. Daedalus is now imbuing human clothing with the same thermostatic cunning.

He is exploiting the 'bimetallic strip' principle: a laminate of two materials with different coefficients of expansion curls with change of temperature. Two-component synthetic fibres are already well known, so it should be easy to bond two polymers of contrasting expansion coefficients, like nylon and polyester, into a highly thermosensitive fibre. Inserted as flock or tufting in a conventionally woven fabric, such fibres will form a velvety 'Cat-fur'. Its pile will fluff up in the cold, but curl over and lay flat in the heat, neatly thermostatting the wearer.

DREADCO's Cat-fur will come with a range of transition temperatures. For coats and other outerwear, it should fluff up at moderate outdoor-air temperatures, so as to respond to changes in the weather. A higher-temperature grade will be used in underwear. Responsive to typical skin temperatures, it will maintain intimate comfort in the face of wide swings of metabolic rate, from the hot sweat of exertion or anxiety to the chill of desperate foreboding.

The ultimate in thermostatted clothing will be a complete one-piece 'Cat-suit'. Each element of its surface will incorporate the right mix of Cat-fur fibres to maintain the skin beneath at its optimum temperature. It will be equally comfortable indoors or outdoors, in winter or summer, in violent exercise or total relaxation. The wearer will need no other garment!

An extreme test of Cat-fur will be at night, in its role as pyjamas or bed-clothes. A sleeper produces so little heat that he needs the maximum of thermal insulation; even so, modern beds (especially duvets) probably overdo it. A time-lapse film of a sleeper looks like a fight with an invisible boa constrictor, but is really a constant search for thermal equilibrium. When overheated, the sleeper must move to a cooler part of the bed, which soon heats up in its turn; when too chilly, he must curl up to conserve heat. This ceaseless unconscious activity is far from restful.

In blissful contrast, a sleeper insulated by DREADCO's Cat-fur will be in perfect thermal equilibrium all through the night. He will never have to move, and will truly 'sleep like a log'. A whole new era of total nocturnal comfort and perfect sleep will be ushered in! The dreary syndrome of daytime exhaustion, with its gummed eyelids and drained enthusiasm, will be abolished; instinctive zest for life, long-forgotten by the legions of Insomniacs Anonymous, will be restored.

David Jones

Link between scrapie and BSE?

SIR—Peter Aldhous recently reported[1] the view that transplacental passage of scrapie infectivity occurs in scrapie-infected ewes. But there are contradictory reports concerning this issue, reflecting our ignorance about the origins, spread and pathogenesis of natural scrapie. The elusive aetiology of scrapie underscores the difficulties encountered in designing and interpreting studies. As we describe here, some view natural scrapie as a viral-like illness whereas others describe it as a genetic disorder that happens to be experimentally transmissible.

Over the past 5 years, molecular biological and genetic data have profoundly altered our views of experimental scrapie in rodents and the trinity of human prion diseases — kuru, Creutzfeldt–Jakob disease (CJD) and Gerstmann–Sträussler syndrome (GSS). Indeed, the application of modern techniques to this enigmatic area of biology has begun to provide explanations about how a disease can be both genetic and experimentally or iatrogenically infectious[2,3]. The main, and possibly only, component of the transmissible particle (or prion) in scrapie is an abnormal isoform of the host-encoded prion protein (PrP)[4], which is generated by an as yet undefined post-translational process. That PrP has a central role in scrapie transmission and pathogenesis is independently supported by studies on the purification of scrapie prions, on the molecular genetics of scrapie incubation time genes and by analyses of infected neuroblastoma cells[3].

Maternal (and lateral) contagious transmission of natural scrapie was first suggested by crosses of scrapied and scrapie-free Suffolk sheep. Progeny of affected ewes rather than rams were about seven times more likely to develop the disease[5]. In a subsequent study of Suffolks crossed with Scottish Blackface sheep a similar but reduced tendency was again apparent; ratios of approximately 1.9 and 1.3 to 1 were obtained in experiments involving 54 and 66 offspring, respectively. A 'background' scrapie incidence of up to 50 per cent in the progeny of unaffected parents, interpreted in terms of lateral contagious transmission, was apparent in this later study[6]. A tendency favouring maternal transmission in Parry's data[7] on twins born of scrapie-infected ewes was noted by Dickinson *et al.*[5], although the numbers quoted for the progeny of unaffected ewes crossed with affected rams do not seem to correspond to the original data. But most of Parry's data on Suffolk sheep revealed no overt tendency for ewes rather than rams to transmit the disease[7]. Parry also found no evidence for contagious transmission — scrapie-free animals produced no affected offspring, even when crossed with scrapied animals.

The hypothesis of maternal transmission can be directly tested by bioassay for infectivity in scrapied ewes. Hadlow and coworkers failed to detect infectious titre in the uterus, ovary or mammary gland of clinically affected Suffolk ewes[8]. Two papers[9,10] have been widely cited as indicating infectivity in the placentae of Swaledale ewes with scrapie. Unfortunately, negative controls for these experiments were not described and the incubation times in the inoculated recipients were scattered; an alternative explanation is that the observed instances of scrapie represent cross-contaminated inocula (but see ref. 15).

A few cases of transmission from experimentally inoculated ewes to offspring been observed[11,12], but in an embryo transfer study by W. Foote *et al.* (personal communication) none of the offspring developed the disease within an observation period greater than or equal to 5 years ($n = 86$). Direct inoculation of control animals in these experiments produced a scrapie incidence of more than 51 per cent. Similarly, negative results were obtained for maternal transmission in experimental scrapie of goats[13]. Early reports suggesting maternal transmission of scrapie in mice have subsequently been strongly challenged. A maternal effect is not apparent in the transmission of either familial or experimental CJD, kuru or GSS.

In summary, the question of maternal transmission represents part of the larger issue of whether natural scrapie in sheep is a contagious disease under normal conditions of husbandry. As bovine spongiform encephalopathy (BSE) is inferred to have arisen by oral-dosing with contaminated feedstuff[14], and given that some scrapie researchers considered that natural and experimental scrapie were not necessarily identical diseases[7,15], the data on natural scrapie may be irrelevant to the anticipated behaviour of BSE. But as the dataset on experimental scrapie contains evidence both for and against 'maternal' transmission, and as there is a potential human health hazard concerning BSE, the resolution of this matter must come from future experimentation. Because our studies with transgenic mice[16] show that the species barrier for passage of scrapie prions between rodent species is likely to reside in the amino-acid sequence of PrP, similar experiments seem relevant in examining the potential for transmission of prions from beef and sheep products to humans.

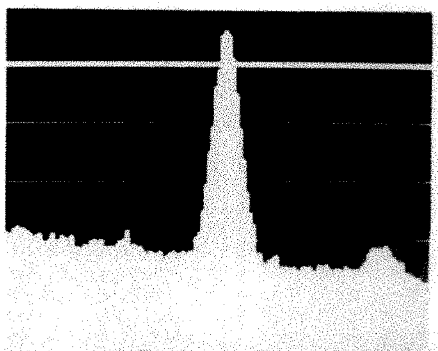
Frustrated crystallographers

SIR—Dover's News and Views article[1], indicating that "many frustrated crystallographers are left wondering why their crystals will not grow large enough or well-ordered enough, or grew yesterday but will not grow today", brought back memories of my own experiences with this problem. When I first joined Professor Tom Blundell's group, good-sized crystals of the newly discovered avian pancreatic polypeptide hormone (aPP) had just been grown by Dr Steve Wood. But the small pot of crystals was soon depleted by low-resolution data collection and by screening more than 30 heavy-atom soaks by precession photography.

Subsequent laborious preparation of new materials and numerous crystallization trials would no longer result in crystals. Suspecting the presence of an unknown co-factor, I analysed the crystals using scanning electron microscopy. The microscope was fitted with an EDAX system which could potentially be used to identify trace elements by measuring their



EDAX spectrum from an aPP crystal indicating the presence of zinc.

characteristic X-ray emission energies.

I placed one of the remaining small crystals of aPP on a sample stub to air dry and to my surprise it did not disintegrate. After coating it with carbon, I examined the sample under vacuum in the microscope and it remained crystalline in appearance. I recorded EDAX spectra over a 400-s time period and observed a peak at 8.63-KeV characteristic of the K_α line for zinc. The addition of zinc acetate to the crystallization experiments resulted in much larger crystals, indicating that the original scavenged zinc must have been limiting[2]. The resulting high-resolution X-ray analysis indicated the key role this divalent ion played in forming the crystal lattice[2,3].

I have also applied this technique to porcine 2-zinc insulin crystals and to freezed-dried iron containing transferrin. The ability to detect and identify traces of heavy elements acting as essential cofactors in protein crystals may provide one escape route for the baffled crystallographer.

Expanding family

Sir—We have recently described[1] a family of six fungal genes involved in mitosis and the regulation of RNA synthesis whose protein products have in common a repetitive sequence motif of 34 amino acids (tetratricopeptide repeat or TPR). Zhang *et al.* (manuscript in preparation) subsequently found 16 tandem TPR sequences in the *crooked neck* (*crn*) gene involved in neurogenesis in the fruitfly *Drosophila*. We have now identified two additional family members in the yeast *Saccharomyces cerevisiae*.

The product of one gene, first cloned in 1983 (refs 2, 3), is a protein of relative molecular mass (M_r) 70,000 and was used for studying the targeting of mitochondrial proteins encoded in the nucleus. The 41 amino acids at the amino terminus anchor the protein to the outer mitochondrial membrane and the rest lies in the cytoplasm. It is this portion that contains seven tandem TPR sequences; this arrangement of TPR repeats is remarkably similar to that of the cell-division cycle (CDC) subset of the TPR family[1]. It is known that a truncated version of the gene, whose product is shortened at the carboxy terminus by 203 residues, including almost all of the tandem TPR domain, is anchored normally but produces cells with the same mutant phenotype as that of cells that lack the protein. Could it be that the repeated sequence domain mediates the interaction of mitochondria with the cytoskeleton much as *nuc2*$^+$ is thought to interact with the nuclear 'scaffold'[4]?

The product of the second gene, *STI1*, is a protein of M_r 66,000 induced by stress but not similar to the HSP70 family of heat-shock proteins[5]. Again there are internal TPR sequences, but of variable length, in an arrangement resembling that of the product of SKI3 gene involved in RNA regulation.

The inferred amphipathic helical structure of the TPR unit[1,4] suggests several possible functions, including protein–lipid interaction and the mediation of protein dimerization. Our recent (unpublished) finding of intragenic complementation between temperature-sensitive alleles of *CDC23* by mutations in different TPRs suggests that protein-protein interactions are necessary for *CDC23* function.

In our original TPR dataset[1], we identified two more highly conserved subdomains, A and B, corresponding to the 'hole' and 'knob' in the repeat–repeat interaction model of *nuc2*$^+$ function[4]. In the new examples, the B submotif is maintained but there are different patterns of sequence conservation in A. We believe that TPR genes have evolved different functions based both on divergence of TPR sequences and also on the acquisition of separate, unrelated functional domains such as the targeting/anchoring sequence in the M_r 70,000 outer mitochondrial membrane protein and the *zeste*-like domain in *SSN6* (ref. 1). Consistent with this idea, we have now found that single amino-acid substitutions in *CDC23*, which cause a temperature-sensitive phenotype, cluster into two separate domains: the carboxy-terminal TPR sequence block and an amino-terminal domain of unique, unrelated sequence.

Internally repetitive sequences and their statistical significance were identified and characterized by standard methods as described in ref. 1. The M_r 70,000 protein and *STI1* have intra-sequence comparison scores of 7.09 and 12.37 s.d. units, respectively; inter-sequence comparisons with other members of the TPR family yielded scores ranging from 3.44 to 12.43 s.d. units. Only the repeats of highest significance are shown. Starred columns, the most highly-conserved positions in the aligned sequences. The original TPR motif was based on 47 repeats from five different proteins and showed two more highly conserved subdomains labelled A and B and represented by the sequences W..LG..Y and A...(Y/F)..A...P, respectively (ref. 1). The CDC subset of TPR proteins includes *CDC23, CDC16* (*S. cerevisiae*), *nuc2*$^+$ (*S. pombe*) and *bimA* (*A. nidulans*); the RNA regulation subset includes *SKI3* and *SSN6* (*S. cerevisiae*). To facilitate comparisons with new candidate TPR genes, a file containing all known TPR protein sequences, as well as suggestions for quantitative comparisons, is available from M.S.B.

Proportional time

Sir—If there is unease with the idea of a defined moment for the Big Bang, with no temporal predecessor, why not adopt E. A. Milne's logarithmic proposal, where $\tau = t \log(t/t_0) + t_0$, with τ as dynamical time and t as conventional time (*Proc. R. Soc.* **A158**, 324–348; 1937)? As Milne remarks, the epoch of creation t=0 on the kinematic scale is measured by $\tau = -\infty$ on the dynamical scale.

Indeed, more generally there is a case for thinking of time in proportionate rather than in arithmatically progressive terms. In sensory physiology, strength of sensation is usually proportional to log(stimulus); in pharmacology, drug effect is usually proportioned to log(dose); and on a wider canvas, wage negotiations, inflation, growth and what-not, are almost always expressed in proportionate terms. Why should the philosophy of time restrict itself to an unnatural arithmetical scale?

Historical light on photography

SIR— During the historical session of the French Academy of Sciences on 19 August 1839, F. Arago disclosed the now well-known daguerrotype process invented by Daguerre[1]. But a few years earlier, in 1816, Joseph Nicéphore Niépce obtained the first negative picture on a paper coated with silver salts and placed in a crude camera obscura[2]. The picture was sent in a letter to his brother, but it was not fixed, and he also failed to produce a positive from it.

Niépce investigated numerous light-sensitive compounds which he classified into three types with respect to the effect of light: "colouring properties, discolouring properties and solidifying properties". He eventually succeeded in irreversibly fixing on a support the reflection of light from a landscape by using asphalt spread on glass, stone or metal. In 1829 he described his process which was published 10 years later[1]. Niépce had discovered that bitumen hardens on exposure to light, thus making it possible to capture the imprint of light and shadow of an image by removal of the unexposed areas with an appropriate solvent.

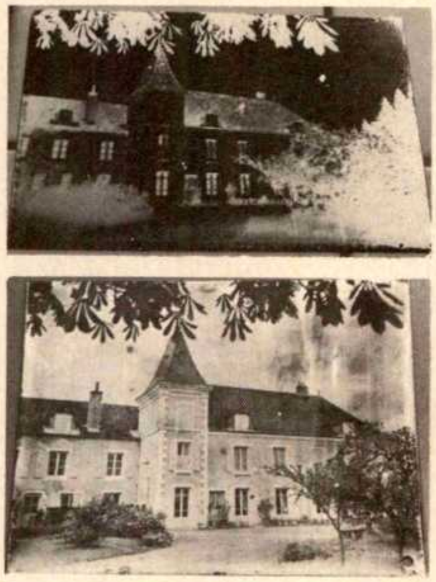
But the process, termed heliography by Niépce, remained obscure. Only a unique picture called *Point de vue du Gras*, obtained by Niépce in 1826, is known and his work cannot easily be evaluated from this single heliograph.

We have attempted to reproduce Niépce's technique and in June 1989 were able to produce the first heliograph ever made since Niépce's time[3]. We followed all his written methods, and experimentally determined the exposure time, which he never mentioned. The heliographic process is, in practice, rather different from the interpretation given by historians and provides a clearer understanding of some of the explanations given by Niépce in his letters.

The photosensitive compound used by Niépce was bitumen of Judea, or asphalt[4]. In Niépce's process, bitumen is dissolved in oil of lavender and spread as a thin layer on a well polished silver-coated plate as a varnish. This constitutes a photosensitive film which, under the action of light, partially loses its properties of solubility due to a crosslinking process[5]. This variation of solubility with dose allows one to dissolve the areas where the varnish remains soluble — those which have not been illuminated — while it becomes insoluble in the exposed areas.

The bitumen we used is a commercial product (Prolabo) in the form of a brown powder. Our preparation of the well-polished silver plate, covered with the bitumen varnish to obtain a thin golden brown film follows exactly the operations described by Niépce[1]. The optical absorption spectrum of a thin film of bitumen prepared from a bitumen solution (3 g in 10 ml of lavender oil) shows an optical density at wavelength's under 500 nm.

In the literature of the history of photography, the formation of an image by the Niépce process is explained as the simultaneous hardening and whitening of the bitumen under the action of light and thus would be a direct positive process[2,6-8]. Our first experiments were performed by irradiating homogeneously the light-sensitive plate either with sunlight or with a halogen lamp whose light intensity was controlled; the bitumen hardened under these conditions. But no change in the golden brown colour was detected even after a long irradiation with visible or ultraviolet light. Niépce said that no colour variation is observable after exposure to light. There is no whitening of the bitumen with light, contrary to what has frequently been claimed[1,2,6-9].



Top: negative image obtained with bitumen of Judea by using contact printing (see text). Light areas correspond to bright silver, dark areas consist of crosslinked brown bitumen. Bottom: direct reaction of iodine vapours on the negative image leads to the formation of silver iodine only where the bright silver of the negative image was apparent. Under the action of light these bright areas turn black. After complete removal of the bitumen still present, the positive image is obtained. (*Le Gras*: Niépce's house at St Loup de Varennes near Chalon-sur-Saône, France).

Niépce's method of obtaining a positive image is the following: the unprotected bright silver is blackened by submitting the negative plate to iodine vapours. This leads to the formation of silver iodine at the surface of the plate which is then transformed, under daylight, into finely divided black silver. The last operation consists of stripping the hardened bitumen off the plate with alcohol. In its final form, no trace of bitumen is left on a heliograph. The bitumen plays the role of an intermediate compound, like a negative image laid on silver. Iodine vapours penetrate the different areas of bitumen, proportional to their density, and restore all the variations of greys from black to white. The shadows are made of black colloidal silver, while the lights are polished silver. The image we obtain has a high resolution (80 lines per mm) and good reproduction of shades of grey.

Our second important result concerns the exposure time. Many hypothesis have been suggested[2] as Niépce never clearly mentioned this parameter. Three different methods have been used to obtain heliographs: (1) by projecting a slide magnified from 24 × 36 mm to 80 × 100 mm with a slide projector equipped with a 150-W lamp and a *f* 2.8-aperture lens (about 55,000 lux on the bitumen). The exposure time ranges from 10 to 15 hours. (2) By contact printing under the Sun (about 350,000 lux) of a positive modern photograph on a transparent film. The exposure time varied from 1.5 to 3 hours. (3) In a camera with a *f* 3.5 aperture lens (similar to Niépce's method for obtaining heliographs with a camera obscura). In this case, our experiments showed that the level of light on the plate was 5,500–11,000 lux. Therefore an exposure time 60–100 hours is required. These times are in agreement with those mentioned by Biot in 1839, who wrote that the Niépce process needed 2 or 3 days under a very intense light to obtain an image from nature in a black box[10]. Thus Niépce could only heliograph static subjects in very intense light. But Niépce's discovery opened the way to his successors.

The exceedingly low sensitivity of bitumen of Judea explains why the different steps of the whole process, such as the preparation of the varnish or its dissolution after exposure, can be carried out under room light without damage. It seems that the determination of the exposure time is the main obstacle preventing the reproduction of Niépce's process. Some historians have eronously concluded that the exposure time was 8 hours for a landscape illuminated by a bright Sun[9].

Stripes on a pterosaur wing

SIR—D. Martill and D. Unwin in their recent Letter to *Nature*[1] described a pterodactyl fossil in which details of the soft tissues of the wing membrane were preserved. Scanning electron microscopy revealed an epidermal layer on one surface of the specimen, with coarse ridges and finer furrows, below which was a spongy layer said to contain blood vessels. Martill and Unwin interpreted this 'stratum vasculosum', together with an underlying coarsely crystalline layer, as the dermis. Below that was a layer they described as striated muscle, which apparently formed the middle of the original membrane, but the authors did not explain why they thought this layer was muscle. It consisted of polygonal prisms with a maximum diameter of about 40 μm, on which Martill and Unwin said that "transverse striae and nuclei" were visible at high magnification. They did not illustrate these striae, or give any details. The features seen in the electron micrographs would presumably be annular ridges or grooves around the circumference of the prisms.

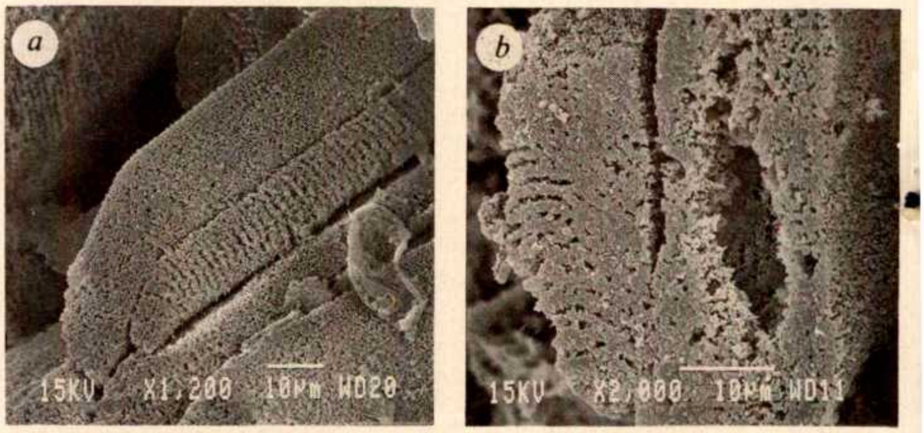
There are examples of fossils in which very fine details of the surface of soft tissues have been preserved, apparently by the deposition of a calcite 'mould' of the surface, before the tissues decayed[2,3]. This process preserves only surface relief, and it is unlikely that intracellular structures such as muscle striae (sarcomeres) could be preserved in this way. The sarcomeres of fresh striated muscles have a solid appearance under the light microscope, but are not accompanied by annular corrugations on the surface of the fibre. It is conceivable that the sarcolemma might be deformed into annular wrinkles in a strongly contracted muscle fibre, but striae formed in this way would not represent sarcomeres. For a surface mould to be formed that would show such features, the muscle fibres would in any case have to remain in tetanic contraction for some time after death, which seems unlikely. On the other hand, passive elastic fibres would contract when the animal died. Elastic fibres, if they were enclosed in a relatively inextensible sheath, might well exhibit a surface pattern like that reported by Martill and Unwin in their paper.

I reviewed evidence[2] indicating that the ridges on the wing surfaces of certain pterosaur fossils are not stiffening fibres, as had been previously thought, but are wrinkles in the surface of a soft membrane, caused by the contraction of robust (but unseen) internal elastic fibres. These hypothetical elastic fibres would have to be orientated transversely to the wrinkles, not parallel to them as shown by Martill and Unwin in their Fig. 3*c*. Martill and Unwin's observations could be interpreted as the first direct evidence for the existence of these fibres.

C. J. PENNYCUICK

Department of Biology,
University of Miami, PO Box 249118,
Coral Gables, Florida 33124, USA

MARTILL *ET AL.* REPLY—Pennycuick suggests that we may have misinterpreted the polygonal fibres in our exceptionally well-preserved pterosaur wing membrane from the Santana Formation (Lower Cretaceous) of Brazil. We concluded that the fibres represent striated muscle replaced by cryptocrystalline calcium phosphate. Pennycuick believes that the fibres represent his hypothetical 'elastic' fibres[2], which he suggested as a possible mechanism for contraction of the flight membrane on the basis of impressions in fine-grained sediments. We here review our evidence for interpreting these fibres as striated muscle and report briefly on our new studies of this tissue.



a, Striated muscle fibres from pterosaur wing membrane from the Santana Formation, Brazil. *b*, Oblique section through individual fibre demonstrating continuity of surface banding through body of fibre. We interpret the banding as fossil sarcomeres.

The most common soft tissues found in the Santana Formation are striated muscle and gill lamellae of elopomorph fish[4]. Here, the muscle fibres are found in their original myomeres, and there is no doubt that they represent fossil striated muscle fibres. They even show sarcolemic membranes, cell nuclei, myoseptal membranes and sarcomeres[5]. Preservation is by replacement with calcium phosphate as demonstrated by powder X ray diffractometry. The fibres we found[1] resemble very closely the muscle fibres found in the fish. Furthermore, pterosaur fibres display a regular banding seen on the surface.

Pennycuick suggests that striated muscle would not be preserved as a series of ridges on the surface of a fibre. Indeed in this respect he is correct. Our striated muscle fibres are not preserved as a series of ridges. Instead, they are preserved as a series of stacked 'disks' along the length of each fibre (*a* in the figure). We have carefully made a new section through the preserved muscle fibres such that several individual fibres have been cut obliquely, showing that the disks are present through the fibre, as would be expected if sarcomeres were preserved (*b* in the figure).

Pennycuick's surprise at the exceptional preservation of our material could be because the material he examined was represented by external moulds in fine-grained micrite. This style of preservation can only reveal details of external surfaces, the resolution of which is governed by the grain size of the sediment host. Our material, on the other hand, is a replacement, in three dimensions, by crystallites with an average length of 300 nanometres. The resolution achieved by this style of preservation allows the identification and accurate observation of three-dimensional intracellular structures. We are confident that the fibres are those of striated muscle tissue.

But our new section shows some structures between the muscle fibres and the stratum spongiosum (labelled sparry calcite and kerogen in Fig. 3*a* of ref. 1), as yet unidentified, that could be Pennycuick's hypothetical elastic fibres or Wellnhofer's stiffening rods[6]. In either case it appears that the pterosaur wing membrane is a highly complex organ, not just a piece of stiffened skin.

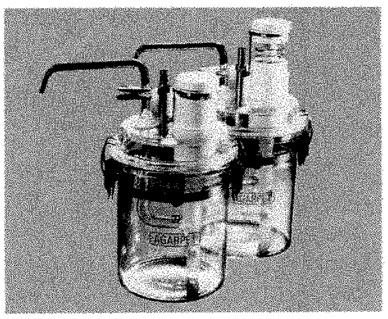
AGARPET™

HIGH SPEED AGAR DISPENSER



Agarpet™, an adjustable dispenser, is an ideal tool for preparing agar plates easily and rapidly. It is autoclavable and designed to prevent contamination.

Features:

- ∗Volumetric Accuracy < ±5%
- ∗Can be used to dispense agar into tubes as well.
- ∗Two sizes available (0~25 ml and 0~50 ml dispensing ranges) and two types for the both sizes (with/without springs for pulling up the plungers).

ANNOUNCING

PORTLAND PRESS

The publishing company of the Biochemical Society

On 2 January 1990, the Biochemical Society founded Portland Press, built on over 75 years of experience of biomedical publishing.

Portland Press will actively seek new publishing opportunities in all areas of biomedicine while continuing to serve the international scientific community with its expertise in journals, notably the *Biochemical Journal*. The resources of the Press's newly refurbished marketing and distribution centre at Colchester, now equipped with a Vista computer system, are available to other publishers.

The Biochemical Society continues to grow in membership and influence worldwide, and the establishment of Portland Press will provide the Society with the means to increase the range of its activities and membership services.

Aims and Scope

Mammalian Genome will focus on experimental, theoretical, and technical aspects of genome organization and evolution for mouse, man and other mammalian species.

Special emphasis is placed on:
- genetic and physical maps
- analysis of gene complexes and complex traits
- DNA sequencing as related to genome organization
- comparative gene mapping
- new techniques
- informatics as related to genome analysis
- genetic analysis of animal models for human genetic disorders

Matters of life and death

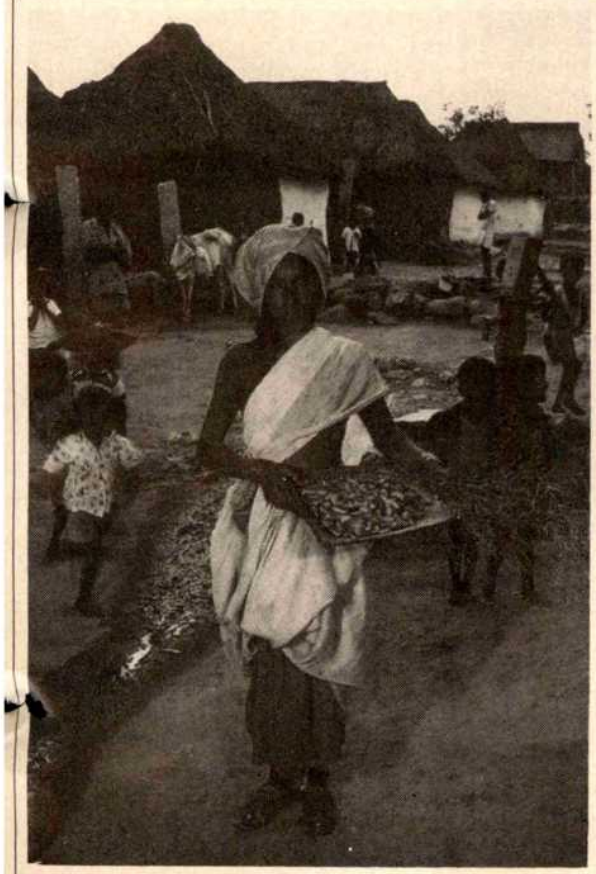
F. E. G. Cox

Lives at Risk: Public Health in Nineteenth-Century Egypt. By LaVerne Kuhnke. *University of California Press: 1990. Pp. 233. $40.*

NINETEENTH-century Egypt was not an idyllic place. Dysentery, cholera and Egyptian chlorosis were endemic in the villages and sewage often contaminated the water supplies of Alexandria and Cairo. Malnutrition was everywhere and epidemics of smallpox and plague had ravaged the whole country by the turn of the century. The medical expertise that did exist was largely based on mediaeval Arab medicine but practised, not by professionals of earlier centuries, but by hakims whose training consisted of copying the standard texts in order to memorize them. It is against this background that LaVerne Kuhnke traces the development of public health care in Egypt, with numerous side glances at the implications for health in the developing countries today.

Changes in Egypt began when Muhammad Ali, who had seized power as governor in 1805, formed a conscript army and, anxious about its health, introduced Western medical institutions and technologies which, Kuhnke argues, were not always appropriate to the needs of the country. In 1827, Ali established a Western medical school modelled on those in France and staffed largely by Italians. Twelve of the first batch of graduates continued their training in Paris in 1832 and five returned to form the nucleus of the school. Their successors made significant contributions to medicine, the most notable being Griesenger, who found that Egyptian chlorosis was caused by hookworms, and Theodor Bilharz, who discovered *Schistosoma haematobium*, the causative agent of the disease that now bears his name, bilharzia. In 1832, a medical school for the training of hakimas (women licensed to practice medicine) was founded, a remarkable achievement in a Muslim society. By 1840, responsibility for health care had also passed to headmasters in schools, with severe penalties for negligence. Thus, by the middle of the century, the elements of public health care had been well established and epidemics were no longer allowed to run unabated.

Epidemics of cholera in 1831 and plague in 1834–36 were countered by rigorous quarantine regimes. An international quarantine board had been set up some years earlier on advice given by the French council of health, but the 1831 cholera epidemic caught it unprepared. By 1848, as a result of a combination of quarantine measures and the implementation of British sanitary reforms, the next epidemic, although severe, was more easily contained. Plague also ceased to be a serious problem and after 1844 it disappeared from Egypt for 55 years. Vaccination against smallpox was both efficient and effective and between 1837 and 1840, 61,000 childen had been vaccinated in Cairo alone although there was strong opposition and non-compliance in many villages.



More than half of India's land surface is cropland — the soils are fertile and robust, and rainfall adequate. These factors have combined to make India the most densely populated large nation on Earth; 80 per cent of its inhabitants live directly from the land or in the service of small rural communities. From *Man on Earth*, just published in Penguin paperback, by John Reader. First published by Collins in 1988, the volume records the author's attempts to understand humanity. Reader looks at culture from a functional point of view, looking at how adaptation and regulation have promoted the continuing existence of people in a wide variety of environments throughout the world. Illustrated with the author's own superb photographs, price is £9.99.

The evidence presented seems to suggest that the control schemes used actually worked, but Kuhnke questions whether the Western ideas on which they were based were appropriate for Egypt. This is the weakest part of the book and detracts from an otherwise scholarly and dispassionate work. The author perceives an apparent distinction between "authentic medicine", equated with curative medicine, and community and public health concerns, concluding with these words: "As long as the West upholds urban hospital-based curative medicine for the individual as the ideal for 'health care', the lives of rural Egyptians and many others may continue at risk." This is an entirely false picture of how biomedical science interacts with the needs of the developing countries (see, for example, *Biomedical Science and the Third World*, edited by Barry Bloom and Tony Cerami, *Annals of the New York Academy of Sciences*, Vol. 569, 1989). Tropical medicine, and the World Health Organization in particular, is as much concerned with prevention as with cure and the two run together. It is a pity that Kuhnke did not consider bilharzia, as this is a disease that has always been associated with Egypt and from which much can be learned. The conflict for public health strategy is between the needs of water for irrigation and the consequent inevitable spread of the snail vectors. Control of bilharzia is based both on snail control and on chemotherapy, which is essential to reduce contamination of snail-infested waters.

History does repeat itself, and the resistance of some villagers to vaccination and their failure to return for booster doses is still a problem today. It is also interesting that seven of the first twelve graduates of the medical school chose to remain in Paris, and the pile of examination scripts now on my desk reminds me that twentieth-century students also learn large parts of textbooks by heart. ☐

In the balance

Edward Abraham

Miracle Cure. The Story of Antibiotics. By Milton Wainwright. *Blackwell: 1990. Pp.196. £16.95.*

MILTON Wainwright has written a readable pot-pourri. Much of it is concerned with the assessment of credit for the discovery of the clinical value of penicillin and streptomycin, but the author strays into other areas, including a description of some bizarre procedures that have previously been claimed to cure bacterial infections and the fiasco of the antibiotic patulin and the common cold.

The author, who is in the Microbiology Department at the University of Sheffield, states that he has "attempted to redress recent attempts to downgrade the role played by Sir Alexander Fleming in the discovery of this most famous antibiotic". Some may wonder whether this is necessary, for Fleming's name has been embedded in the public mind, while Florey's and Chain's have not. Yet Fleming was not elected to the fellowship of the Royal Society until 1943, 20 years after he had first been proposed by Almroth Wright. Wainwright suggests that this should carry little weight with "anyone who is familiar with the routes by which one can succeed to this august body". The precise implication of his phrase is not clear. But great trouble was taken to ensure that Fleming's candidature was not adversely affected by publicity for the findings in Oxford in 1940 and 1941. And it should be remembered that the Royal Society is concerned with science, not merely with medicine.

Fleming's chance discovery of penicillin has never been seriously disputed, nor has his early belief that it might be clinically useful for local application to infected wounds. The vital discovery at Oxford, which receives little emphasis in the book, was that even exceedingly impure penicillin could cure generalized and life-threatening infections when introduced into the blood stream. It was this that gave penicillin its outstanding medical importance. All that is arguable is whether Fleming could have demonstrated this property in mice if he had thought of trying to do so.

This book contains several interesting anecdotes which may not be widely known. Appropriately, it describes in some detail the striking success in Sheffield of Dr C. G. Paine, whose penicillin-containing culture filtrates from Fleming's *Penicillium* were used for local treatment of eye infections in about 1930. Paine never published these results, but later he sent notes on the cases to Florey. These notes (not mentioned by Wainwright) were reproduced in 1949 in *Antibiotics* by Florey *et al.*.

Wainwright provides simplistic and slightly misleading accounts of the chemistry of penicillin and the semi-synthetic penicillins and cephalosporins. Because all these compounds have a four-membered β-lactam ring it might have been more appropriate to have placed them in the same section of the book.

The discovery of streptomycin was reported in 1944 by Schatz, Bugie and Waksman at Rutgers University; this antibiotic was later found to be effective in the treatment of tuberculosis. This book describes how all was well between Waksman and Schatz until Schatz discovered that Waksman was receiving money from Merck and began a lawsuit for a share of royalties. The case ended with a partial victory for Schatz. However, when a Nobel prize was awarded to Waksman alone, Schatz could not bring himself to remain inactive but, predictably, he gained nothing from his activity. Wainwright states that he has tried to redress an historical imbalance, "this time in favour of Albert Schatz". Whether the balance needed redress is at least open to question. Perhaps Waksman was ungenerous to Schatz and too secretive. But it seems that Schatz failed to appreciate that he was a research assistant to a man who had opened a wide field of investigation that had already led to the discovery of streptothricin. What is beyond doubt, however, is that misjudgements by Waksman and Schatz brought them both a great deal of misery.

The Hutton picture Company

Fleming — "embedded in the public mind".

This book is well produced. But some readers would find a more detailed index more useful and others might appreciate the addition of a few primary sources to the author's suggestions for further reading — to redress its balance. ☐

A way through the jungle

Colin Gough

Physics of High-T_c Superconductors. By J. C. Phillips. *Academic: 1990. Pp.393. $55, £36.*

ALMOST four years after Bednorz and Muller's Nobel prizewinning discovery of superconductivity in the layered cuprate compounds, the unexpectedly high transition temperatures of these materials remains unexplained. It is frequently claimed, with some justification, that there are as many theories for the layered cuprate high-temperature (or HTC) superconductivity as there are groups working on the problem. Keeping abreast of the literature remains a daunting task for even the most experienced researcher.

A book designed to summarize and explain the physics of HTC superconductors is therefore specially welcome, particularly when the writer is J. C. Phillips, who has made many significant contributions to the theory of the electronic and phonon properties of solids including conventional superconductors.

In aiming "to cut a well-marked path [through a literature] as forbidding as the darkest jungle", Phillips has selected a rather special path, carefully chosen to support his view that HTC superconductors are really no different in kind from previously known superconductors. He is sufficiently confident to state "there is no room for doubt that it is lattice instabilities and not magnetism that produce high-T_c superconductivity just as much in cuprates as in intermetallic compounds". Relatively little attention is drawn to other dangerous animals lurking in the jungle in the guise of theoreticians with diametrically opposed views.

The original Bardeen–Cooper–Schrieffer (BCS) model successfully accounted for superconductivity in terms of an indirect attractive electron interaction leading to superconducting pairing via lattice vibrations. This mechanism appears to place an upper limit for superconductivity of around 40 K (−233 °C) — well below the current record for HTC superconductors of 125 K (−148 °C). However, Phillips emphasizes that the layered cuprate HTC superconductors are much more complex structures than the theory was originally developed to describe. Matthias, who spent a lifetime in the quest for higher temperature superconductors, wo[illegible] have claimed that the cuprate superconductors were "tricking nature" into circumventing the apparent boundaries of conventional BCS theory.

To support this thesis, Phillips first presents an extensive background to electron-lattice interactions in old-style superconductors including simple elemental and binary alloy superconductors, binary and ternary compounds, such as the A15 and Chevrel phases. The superconducting cuprates are ternary, quaternary and even more complex chemical compounds — very much more complicated chemical structures than those usually studied by solid-state physicists.

Phillips describes the most important HTC compounds known up to about a year ago and argues the case for superconductivity via low-frequency lattice vibrations or instabilities. Two of the most carefully studied HTC superconductors are $(La,Sr)_2CuO_4$ and $YBa_2Cu_3O_{7-\delta}$, in which the superconducting properties are controlled by strontium and oxygen vacancy dopings, respectively. The relatively facile diffusion of oxygen in the $YBa_2Cu_3O_7$ structure is related to soft lattice correlations involving oxygen vacancies — one of 'nature's tricks' to give superconductivity at 92 K for this compound.

Any successful theory must first account for the anomalous normal state properties. Others have claimed that the remarkably linear dependence of resistivity on temperature common to all the layered HTC compounds reflects an intrinsic property of the electrons in the layered cuprates. Phillips presents a more mundane explanation in terms of electron scattering by the same low-frequency lattice vibrations that ultimately lead to superconductivity.

Who is right remains an open question. On balance, more recent measurements would tend to favour the former view. But it would not surprise me if Phillips turns out to have the last word. The ability of theoretical physicists to adapt their theories to fit inconvenient experimental facts is legendary. Experimentalists can also all too easily become locked into believing the current fashionable theory, with no better justification than other competing but less fashionable theories. At this stage in the development of our understanding of HTC superconductors it would be wise to keep an open mind.

Provided the reader recognizes that this book is not an introductory text but is a research monograph intended to argue a particular point of view, it can be strongly recommended — particularly to those with a solid-state physics background. ☐

Richard Davenport-Hines

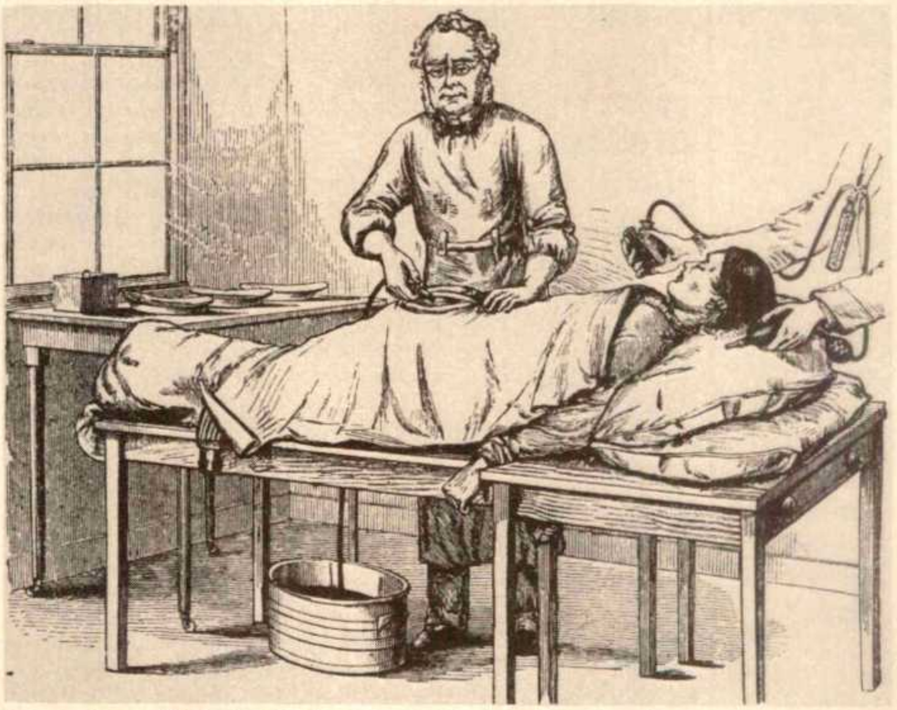
The Science of Woman: Gynaecology and Gender in England 1800–1929. By Ornella Moscucci. *Cambridge University Press: 1990. Pp. 278. £35, $49.50.*

THE history of childbearing is the subject of several recent and excellent books. In addition to Renate Blumenfeld-Kosinski's study of mediaeval caesarean births entitled *Not of Women Born* (Cornell University Press, 1990), there is Valerie Fildes' *Wet Nursing* (Blackwell, 1988) which traces changing attitudes to breastfeeding from antiquity to the present day, and *The Politics of Maternity Care* (Oxford University Press, 1990), in which Jo Garcia and her colleagues have collected a range of historical essays on services for child-bearing women in twentieth-century Britain. This burgeoning literature is now joined by Ornella Moscucci's study of the influence of gynaecological ideas and practice on scientific notions of gender.

Moscucci focuses on London teaching hospitals, but the implications of her study are wider. She questions science's autonomy from society, and challenges the neutrality of its mediations, arguing that the social relations between men and women in the nineteenth and twentieth centuries were reflected in medical notions about masculinity and femininity. She shows deftly and authoritatively how the personal and professional circumstances of British gynaecologists fashioned both the ruling principles of gynaecology and affected the treatment that was offered. She analyses how the wish for professional exclusiveness turned gynaecological practices into weapons in the battle for professional hegemony — for example, how the "envy, hatred and malice" which existed between surgeons and obstetric physicians, especially in the 1884–1929, was fired by controversy over the issue of ovariotomies. The ill-effects on patients when hospital hierarchies become too ruthless in their self-perpetuation makes sad reading.

The scientific study of femininity in nineteenth-century western Europe began as a genre combining scientific findings with literary quotations and philosophical speculation. It fastened onto the processes of puberty, menstruation, childbirth and menopause as indications of an essential animality in women, with the result that medical writings increasingly depicted women as unstable, illogical and the victims of their own bodily emergencies. The subordination of women was enforced by medical teachings, while female sexuality was represented as a threat. An article in the *Obstretical Journal of Great Britain* in 1874 typically described women as the "reproductive servants of their race", and a decade later a leading obstretical textbook depicted the ovary as "ever struggling for supremacy, and cannot long be kept in subjection". The physiology and pathology of the female sexual system were represented as defining women's personalities. As a physician wrote in 1916, "it is because of all the internal secretions that woman is what she is".

Moscucci is far from representing all women as the passive recipients of male medical care, and shows how many people



Ann Ronan Picture Library

Thomas Spencer Wells, the British gynaecologist who perfected ovariotomy.

esisted inappropriate treatment by men. Her book offers many interesting sidelights on issues of female surgery, on the practice of antisepsis, on the use or abuse of the speculum, and on craniotomy as a technique in childbirth. She recognizes the complexities of her subject, and neither adulates physicians as infallible scientific titans nor lapses into the crude petulance of other medical historians who tend to present all patients as the victims of despotic medical authority.

This monograph is the latest volume in the Cambridge History of Medicine series, which is reliably distinguished by scrupulous research and fine historical judgement. (Moscucci is writing the anniversary history of Britain's Royal College of Obstreticians and Gynaecologists.) *The Science of Woman* maintains the quality of the Cambridge series, and although it has too much of the tautness of a PhD dissertation, it is imaginative and well-written. Moscucci's insights have been enriched by her reading in modern feminist historiography, but she dissents from some of its orthodoxies in passages which are notably reflective and honourable. The integrity of her ideas and the honesty of her doubts are as impressive as the range and power of her research. ☐

Peter Coles

Trois Pattes pour un Canard (Souvenirs d'un biologist). By Etienne Wolff. *Editions de la Fondation Singer-Polignac, Paris: 1990. Pp. 201. FF130.*

A CELEBRATED experimental embryologist, former director of the respected Collège de France and member of the Académie Française, Etienne Wolff has been nicknamed "the monster man". Although he dislikes — and rather resents — the title, it was inevitable. His most well-known work has been to produce live monsters in the laboratory — cyclopean chicks, a duck with a third leg where its tail should be, birds with heads sprouting from their intestines and others, equally grotesque. Commonplace in contemporary embryology, teratology was an unfashionable and little explored domain in the 1920s. Now, at the age of 86, Wolff has written a set of 'biographical essays' and a short note on his research to allow us a peek behind the off-putting nickname.

The image Wolff gives us of himself is sometimes candid, but the 'essays' remain mostly rather superficial and arbitrary. The overall theme is autobiographical, but the essays do not fall into chronological order.

Sandwiched in between "childhood" and "orientation of my studies and career", for example, is a chapter on "Judaism and anti-semitism". After a lifeless and rather banal description of his trips to Japan, the United States and the Soviet Union, there is a chapter on "animals and me", where he defends animal experimentation, saying that real cruelty is found in the commercial exploitation of animals, not in the laboratory. But accusations of cruelty associated with his research obviously weigh heavily, despite his light-hearted self-mockery, since almost too much space is given to show he is an animal lover. While the front cover shows a disturbing picture of a three-legged duck, the back cover has a picture of the author cuddling his own cat, "Grouillot".

At the beginning we are treated to anecdotes about Wolff's childhood and his early education, including descriptions of a Paris with steam trams and open-topped buses. Yet these do not really come alive, partly because the manuscript does not appear to have been edited, leaving a cumbersome and repetitive prose. Then there is a sketch of the meandering university studies that led from a degree in letters to a research post — rare at the time — at the Institute of Embryology of the University of Strasbourg. Here began his initiation to embryology and agement to explore the largel area of experimental teratolog

Early in his career, Wolff remarkable discoveries. He fo hormones, not proteins, det sex of chicks and that gen changed in mid-course of de He also found that very specifi an embryo at a given date in h consistently produces a given sity'. With the outbreak of career was suddenly interrup 1940 he was taken prisoner. H next five years in prisoner-of-w Austria and Germany whe handful of fellow academics, 'mini-university', giving lectur soldiers. His two books, "Sex and "The Science of Monsters" after the war, were both writte in Germany. Returning to after the liberation, he built u laboratory with a staff of 50. T when he was awarded a chair at de France in Paris, where his la the Bois de Vincennes becam the Mecca of Embryology.

Wolff says very little about h in this book. In a mere 50 page 200 he describes how he coul regularly and systematically, 'double' monsters, cyclops an cephalic chicks (with heads breasts). Other work include organ cultures *in vitro* and ch sex of chicks. But although he dispel the idea that he is a ki Frankenstein" — most of hi appear spontaneously in natur not told why this work is impor

Much space is devoted to Wolff's teachers, to friends m prisoner-of-war camps, and t eagues, yet even these some depth. Similarly, for a Jew himself in the hands of the Na who also experienced the antis Pétainist France — Wolff's c antisemitism is surprisingly and even comes across as an a resents the word 'Jew', prefer called an Israelite — ironically terms used by Arab antisemites

All in all, this book will plea friends, colleagues and fellow cians. But it does little to "sell" to a broader public and gives a d ingly reluctant, or over-modes of the life of one of the leading century French biologists. O help but come away with the im a brilliant, but very sensitive while having enjoyed the highes from his peers, has never com with the abuse from his detracto

The resurgence of science in France

The Socialist government of France has indeed done wonders for the health and achievement of French research, but there is a raft of problems — some of them long-standing — still to be resolved.

FRANCE, once the most conservative country in Europe, has become a land of technology buffs. People reserve seats on the high-speed trains whizzing everywhere (as well as theatre tickets) by Minitel, the domestic video-tex machines that have swept the country — and which could not have functioned if the telephone system had not been superbly modernized in just ten years. France has also provided the impetus for the creation of the only civil aircraft manufacturer outside the United States capable of selling civil aircraft to the world's airlines. Now it is seeking to drag its European partners into space. What has brought about this transformation? Do its roots lie in the election of François Mitterrand's Socialist government in 1981, and in its deliberate and daring programme to reinvigorate science and technology?

Neither the nature of the transformation nor the importance of its apparent cause should be exaggerated. France remains the Western European state most apt (and able) to claim to be the custodian of European civilization. (The cuisine is merely a by-product.) And technology has not ruined the delectable appearance of France, only some of it. (Too many city mayors have commemorated themselves with ungainly blocks of concrete in mediaeval settings.) Civilization does not, of course, equate with civility, but with respect for the law (including the Revolution's slogan), for intellectual discourse and the importance of the imagination.

The impetus for change in the 1980s is also a prolongation of earlier tendencies. How could it be otherwise when even provincial street names commemorate Descartes, d'Alambert, Pasteur, the Curies (both of them) and the like? The modernization of French science and technology began with the Gaullist government of 1958 and with the creation of the Délégué Général de la Recherche Scientifique et Technique (DGRST), which rapidly transformed itself into a kind of unestablished ministry of science.

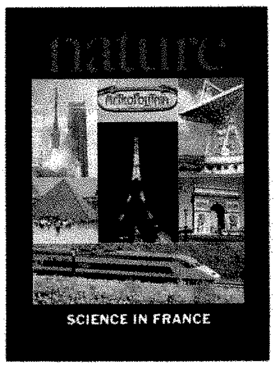
Much of the Gaullist government's support for science and technology sprang from its preoccupation with the military defence of France, but that is when modernization began in earnest. The decision in 1981 that the budget for civil research should increase by more than 16 per cent a year was but the arithmetical consequence of the decision that civil research and development should be 2.5 per cent of Gross Domestic Product by 1985. The name to conjure with is that of Jean-Pierre Chevènement, Mitterrand's first minister of research and industry, now defence minister in Mitterrand's second Socialist government.

The timing of this survey of French science is deliberate: it may not be too soon to estimate the outcome of what an earlier survey (*Nature* **296**, 285; 1982) called "the grand experiment". The outcome should be of interest not only in France but elsewhere, in Britain for example, where governments have taken a more jaundiced view of the benefits of public support for research. But the method of this survey differs from that of earlier exercises of this kind. What follows is not an account of the well-known centres of excellence in France, but is based on conversations (often informal) with working scientists in France and elsewhere, as well as on documents in the public domain.

The good news is quickly stated. In the past eight years, there has been a quite remarkable deepening and broadening of basic research in France. Everybody knows of research groups in France with long-standing international reputations — the mathematicians of Nancy and Marseille, particle physicists at Orsay, solid-state physicists at Grenoble and Strasbourg, molecular biologists at Paris, the Pasteur institutes and Strasbourg, genome mappers and geophysicists at Paris, chemists almost everywhere. The psychological effect of the grand experiment is that all research groups can now realistically aspire to excellence of that kind. And most seem to have that ambition, as well as the enthusiasm that may overcome the usual bureaucratic obstacles.

Two other features of the transformation stand out. First, French researchers seem finally to have buried chauvinism in the search for international collaboration. A united Europe, in particular, is now, not tomorrow. Second, more by accident than design, the French government has engineered a bridge between basic and industrial research that is well designed to keep the technological revolution bubbling away in France.

That is the good news. Some of the bad news will be found on the pages following. □



Science in France

This survey has been written by John Maddox, the Editor of Nature, and Peter Coles, Paris correspondent, both of whom are grateful to researchers and public officials in France for assistance often given at short notice. Cover photos: Feature-Pix/CNES-CSG/SNCF-Lafontant.

Flies in the ointment

French research has been a great success, but there are structural weaknesses in the system that cry out for attention. French science is in better shape now than ever, so why is there so much talk of emergency, even crisis? One of the strangest features of France's distinctively explicit way of managing research — every major item of public expenditure is explicitly analysed in advance — is the recognition that rationality can often be the harbinger of muddle.

What follows is a stark list of those features of the research enterprise in France that cry out for attention. To the extent that they amount to complaints against the present system, they represent either the opinions of working scientists or are administrative faults acknowledged as such by the managers of the system.

It is important for an understanding of what should now be done that most working scientists are employed directly by the national government. This applies both to those who work for the *grandes organismes* of research (organizations such as CNRS), who acquired the status of civil servants in the early 1980s, and to those who are university teachers. Only during the past decade has the number of technical people working for industrial companies shown signs of substantial growth.

It is also relevant that the national universities are part of a unified national system, lacking the autonomy with which liberal opinion would endow them. Students are admitted on the strength of their performance in the school-leaving examinations, and the power of the universities to impose further selective tests is limited. (But several universities have been seeking to do just that in the admission season now under way, provoking fierce protests.) And the most sought-after degrees are those whose award is validated nationally, on the basis of an approved curriculum and examination.

Against that background, this is where the problems lie:

■ **Universities**. That the universities are in danger of being overwhelmed by their students is generally acknowledged. Wedded to open access by the memory of the troubles of 1968, the government is making a virtue of necessity (see page 133). One danger is that only the most ingenious and tenacious students will acquire a good education in the circumstances that now obtain. Another is that the assumption that research and scholarship are a crucial part of academic work will become even more of a dead letter than it is already.

The government acknowledges that there are problems, and is doing what it can to solve them (see page 134). Principles of good management would dictate that there should be a greater devolution of autonomy to the universities; whether the device of the four-year contract between the education ministry and individual universities will have that effect will, in the end, depend on whether the government can sweeten its contracts with extra money.

Meanwhile, the plan to provide extra research funds to academics through the agency of a committee located administratively within the ministry of education seems an invitation to nepotism and soft judgement which have given French universities a bad name in the past. If the universities are to win genuine autonomy (a necessary condition if they are to ease the centre's financial burden by attracting funds from regional governments), then *France will need its own version of a national grant-making body distinct both from the ministry of education and from established organizations such as CNRS.* Why not begin now, before the suspicion becomes entrenched that the ministry of national education, reconciled to a measure of university autonomy, is planning to control them in the long term by research grants?

■ **Student support**. The legend of impoverished students eking out life in Paris garrets is too affectionately regarded to be exorcised quickly, but French inhumanity towards graduate students needs to be abated, especially now that the ministry of national education has acknowledged that it will not be able to teach students in future decades without more university teachers qualified at the PhD level.

The standard route to academic life is through the qualification of the one-year DEA (Diplôme d'Etudes Approfondies), involving (for researchers) laboratory work. Student support through this period, after a first degree, is hazardous enough, but university DEA committees, usually organized on a disciplinary basis, become the means by which students are chosen to receive grants to continue with a PhD course.

The numbers of grants seem invariably less than the justifiable demand. Often there will be two or three grants to distribute among 30 reasonably qualified students. Those who administer the system are humiliated that they rarely know in advance how many there will be. They and laboratory directors are embarrassed that so many disappointed students embark on research degrees in great hardship. *If the government wants more "docteurs", why does it not ameliorate the hardships of those who would meet its needs?*

■ **Mobility and employment**. One complaint is that researchers, both established people and graduate students, are much less mobile than is good for the French research enterprise. Another is that France lacks a system of postdoctoral fellowships for keeping new PhDs at work while they cut their professional teeth and decide, if successful, what fields they will follow. A third is that scientists joining the research organizations are underpaid, and have to wait too long for promotion.

All three problems are linked, and require a common solution. The habit of immobility is engendered by the system requiring that students seeking a research degree must first acquire a DEA qualification, which entails close relationships with research laboratories at which, as likely as not, success will bring them their first research job.

The lack of postdoctoral fellowships *for French researchers within France* means that the transfer of new techniques from one place to another is impeded, while able and established people cannot quickly acquire the help they need to exploit new ideas. (With a few exceptions, even the most influential research groups in France are much smaller than their opposite numbers elsewhere.)

The solution is so obvious as to be breathtaking. *Why not convert established posts in the research organizations such as CNRS into three-year postdoctoral fellowships tenable wherever in France the holder chooses?*

The result would be that able people would get their first taste of independent research at the laboratories that seem to suit them best, that successful research groups would be better able to recruit the help needed to exploit new opportunities and that successful university researchers would be put on a more equal footing with those at the public laboratories.

This is the simplest change of the system there could be. People already on the first rung of the ladder of public service research would not be displaced or otherwise inconvenienced. There would be no significant extra cost — it would be necessary to endow host laboratories with research expenses, but they arise now when new people start work at the laboratories. And it would be possible for promising research groups successful in the competition for people to become competitively strong in a reasonably short time. One of the glaring defects of the present system is that the best groups are consistently understaffed and overworked.

The management of the public laboratories would no doubt be discommoded by a failure to recruit sufficient postdoctoral help to keep their programmes running, but the other side of that coin is that they would be better able to tell who should afterwards be taken on permanently.

■ **Bureaucracy**. The temptation to suppose that a national government modelled by Napoleon is rife with bureaucracy should be resisted. In reality, the government is both accessible and informal. Ministers consult interested parties, and seem to take good advice wherever they can find it. And while the law is the law, most regulations are decrees, which can be relatively easily amended.

It is nevertheless irksome, and a considerable impediment to the welfare of the research enterprise, that questions of money and of the appointment of people should habitually require reference to the centre. That people should have to travel to Paris to intercede with officials over the rejection of applications for small amounts of money is similarly humiliating and a waste of time whose value is now appreciated in France more acutely than ever. *Now that devolution is under way* (see page 131) *cannot the Paris lawyers find a legal mechanism for behaving as if the government's researchers were honest people?*

There is a particular problem over the acquisition of special skills, computer programming for example. Few such people will work in government research because they can do much better elsewhere, but laboratories cannot employ them even on short-term contracts for fear of creating illicit government positions. And there is not enough money to purchase all the software needed from outside contractors, so that far too many researchers double up as their own programmers. *Even in France, there should be a solution.*

- **Money**. France compels admiration for the changes brought about in the past decade and more in the economy at large, not simply in research. It is now a much more prosperous country, even if there are constant envious looks across the border to the East — at West Germany. *Yet the government may have underestimated the true cost of its ambitions for research.*

The calculation is that no great harm may be done if salaries in the public service are so low that people can easily be tempted away to industry, but that will not be true for ever. Despite the success of schemes for adding to research spending from other sources, there is ample evidence that many able people could do much more were it not for the accentuating lack of operating costs. That, on balance, is not simply a waste of people but is potentially destructive of what must now be the most encouraging feature of French research — the generally growing general conviction that every able person can make his or her mark. ☐

POLITICS AND SCIENCE

Chevènement's legacy to the 90s

WAS Jean-Pierre Chevènement the cause of the transformation of French science in the past decade, or was he himself the product of a process already under way?

The question is still much debated, for which reason it is important that the tense in which it is asked should not be taken as a sign that Chevènement belongs to history or, worse, is dead. As minister of defence in the French government, he spent several days of last month on an aircraft carrier in the Atlantic. One day last week, with three other ministers, he was present at a passing-out parade at the national police college.

Yet there has never been a period in the recent history of the administration of French science quite like the year beginning with François Mitterrand's election as president on 10 May 1981. During the election, the Socialists had made no secret of their ambitions for research, but the reality of Chevènement's plans for increased spending were nevertheless a surprise for many people. The research budget for 1982 turned out to be 25 per cent greater than that for 1981.

This daring leap forward had been planned in advance by a working group under the chairmanship of Professor François Gros of the Pasteur Institute. Mitterrand spelled out his policy for research at a meeting at the Luxembourg palace on the eve of the election. In the international competition for discovery, will France be at the front or the back? We may be poor in natural resources, but we are rich in grey matter. That was the point at which Mitterrand promised that research and development expenditure would be increased to 2.5 per cent of the gross domestic product by 1985 — a promise subsequently written into law.

Chevènement's energy and enthusiasm seem to have been crucial. Gros has told how, soon after the election, he had visited Chevènement to explain that, whatever else was done, "the first essential is to change the relations between people" in research; his fear was that the imposition of new structures and tasks on a research community already disillusioned by neglect would bring further alienation. Why, he asked, not organize a great national colloquium at which these issues could be argued out?

The notion was not entirely novel; in 1956, the Mendes-France government had organized a colloquim at Caen. But neither Gros nor anybody else appears to have anticipated the energy that Chevènement would put into the project, which fitted with his own political position in a syndicalist faction of the Socialist Party.

Between October 1981 and the end of the year, no fewer than 31 three-day meetings were organised throughout France, culminating in a four-day meeting in Paris in mid-January 1982. It is estimated that some 25,000 people took part in the regional meetings.

The organization of this gigantic consultation was carried out by a committee under François Gros, with Dr Philippe Lazar (then the president of the scientific council of INSERM, now its director-general) as vice-president and rapporteur. Even now, Lazar vividly recalls how, after nearly a year's intensive work on the organization of the colloquia, he had been looking forward to a vacation. Instead, Chevènement asked him to move to INSERM right away.

Among others, one of the emergent themes was the importance of research as a means of bridging the economic gap between rich and poor countries, now embodied in the great emphasis in French research on the problems of tropical agriculture. But the overarching theme was that science belongs to the people and is a part of the general culture. ☐

Colloquia galore

JEAN-Pierre Chevènement's most memorable achievement may have been his decision to hold a series of regional colloquia (*assizes*) at which members of the scientific community could voice their aspirations and discontents. Certainly, he has many imitators.

Beginning this year, the ministry of research and technology plans a series of such colloquia dealing with particular fields of research. The first of them, this January, launched "cogniscience" on the psychology and neurobiology communities. Earlier this month at Strasbourg, there was a similar meeting on planet Earth.

Science minister in the early 80s, Jean-Pierre Chevènement.

The objectives are several — to improve coordination in continuing fields of study, to plan how to exploit emerging areas (order and chaos, for example) and to explore the relations between academic studies and their application.

But the Ministry of National Education has now joined in, with a colloquiun at the Sorbonne last month which gave the minister, M. Lionel Jospin, the opportunity to repeat Allègre's slogan "Diversity means equality" (see page 133). ☐

UBLICANISM

The heat of competition

One should not forget that the republican spirit is alive and well in France, more than 200 years after the French Revolution. The grandest people are called "monsieur", as in "Monsieur le Président". And some of the grandest people every day shake hands with those who sit outside their doors, letting through those with appointments and diverting others elsewhere.

Another practical consequence is the institution of the *concours* — the system of competitive examinations by which people compete for places in the public service (which includes student places at the *grandes écoles*, whose *concours* are anonymous — see page 135) throughout France. The objective is to banish nepotism. One Briton working at an INSERM laboratory fulsomely admires the system, which he says should be adopted everywhere.

But there are obvious drawbacks for the management of laboratories. In CNRS, for example, the competition for places (held twice a year) means that particular laboratories cannot be sure that promising PhDs whom they would wish to fill particular slots will succeed in the national competition for places at the first, or second or even umpteenth attempt. Successful directors must have a supply of soft money (perhaps from industrial contracts) up their sleeves.

Promotion is also determined by *concours* — and the chance of success by the low ratio of vacancies to applicants. The obstacles to promotion to the status of *directeur de recherche* (group leader) is one of the chief discontents of young research workers in the public service.

The tendency towards centralism in France, everywhere apparent, also has other origins, mostly Napoleonic. The disadvantages of centralism have traditionally been freely acknowledged, but people have then shrugged their shoulders as if to say that little can be done about them. One of the achievements of the second Mitterrand presidency is that the cosy conventions of centralism are being eroded. The calculation seems to be that French economic growth will be faster if devolution gives regions an influence on their own welfare. That seems to be correct in the case of at least one region in the southwest (see page 131).

But decentralization is being worked out in a centralist fashion; there are the same rules for all the regions, while the devolution of responsibility for education, planning and economic development is far from complete. But in the long run, regional involvement in educational matters could be crucial for research. ☐

PUBLICATION

"We want to play the game"

Director J. C. Duplessey at the CNRS Radioactive Tracer Laboratory (Institut des Faibles Radioactivités) tells how, when he published his first paper in an English-language US journal in 1971, his professor told him that he had been stupid. "Nobody will read it", he was told. But now the boot is on the other foot. "We want to play the game, and we have learned how to do it."

Where and how to publish is on everybody's mind, but there seems only one answer: in English, and in an international journal. The apparently serious suggestions of a few years ago that people's performance should be determined by a points system, with so many points for a paper in journal X, and so many fewer for a paper in journal Y, have mercifully now been dropped. But there is a general understanding that there is no general case for publishing in French in a French-language journal. Then you will not be read by the people you need to reach.

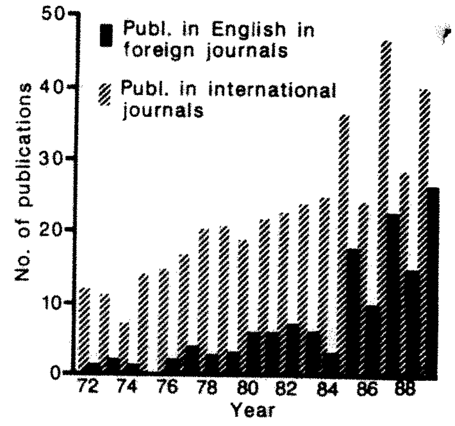
Nor will you be respected by your colleagues and compatriots. The annual reports of many public laboratories include not merely lists of the papers published during the past year, but an analysis of the proportion appearing in foreign-language journals (see, for example, the figure below).

Yet as things are, the change of practice seems to have made little impact on the bibliometric statistics. Recently published figures suggest that between 1981 and 1986 inclusive, the French share of the world's literature fluctuated narrowly and, if anything, that it declined (Martin *et al. Science and Public Policy* **17**, 14–26; February 1990). In 1981, the French share of publications in the US National Science Foundation's file of journals was 5.02 per cent, but had declined to 4.84 per cent in 1984, rising to 4.87 per cent in 1988. (The corresponding figures for the United Kingdom are 8.34 per cent, 8.16 per cent and 8.19 per cent.)

No doubt these figures should be regarded with caution. For one thing, they are inevitably out of date. For another, there is plenty of anecdotal evidence — references to outstanding French papers in well-known journals — to suggest that the benefits of the new attitude towards publication have not yet worked their way through. There is also some weight in the observation of one laboratory director that it was fruitless to go looking for evidence of a resurgence of French science "when we may simply have started publishing in English". But the habit has come to stay.

That the French reputation for chauvinism should be so directly belied is proof of a profound sea-change of opinion, linked with a general appreciation that even the French government's generosity towards research will not enable France to make its own way in a competitive world without external collaboration. So people are also forever on the lookout for opportunities for collaboration, perhaps by the judicious placing of postdoctoral fellows in overseas laboratories, perhaps through collaborations with opposite numbers elsewhere and also through the European Communities.

But compliance does not mean pleasure. For one thing, there are practical difficulties. People whose mother-tongue is French do not write easily in English. (This may be one explanation for the good sprinkling of English-speakers, American or British, in the public laboratories.) More contentiously, it is also asserted that French is intrinsically more capable of clarity — which may be another way of saying the same thing.



In any case, most people seem to hold that while English is now the language in which they must write papers — as it has also become a passable lingua franca of conversation — it will be a matter of great regret if French is altogether abandoned. Philip Lazar, the reflective director-general of INSERM, says he hopes that "the time will never come when no science is written in French".

Nor need it. In contrast with those of the English-speaking world, French researchers still regard the production of books as an honourable occupation. Journals such as *La Recherche*, whose strong suit is high-level popularization, appear to be as much a pleasure to write for as they are to read. And the general popularity of technology as well as the need for interprofessional communication has been a powerful impetus for French technical publishing at all levels.

Yet the clinching sign that the use of English has come to stay must be that the *Comptes Rendues de l'Academie des Sciences* now precedes everything it publishes with an extended abstract in English. ☐

RESEARCH SPENDING

Whatever happened in 1986?

CAN you see politics in a graph? Yes, if it is a graph of French spending on civil research (see right) The 'accordion' effect, as the French say, of policy changes in 1986 and, then, 1988 cries out for explanation.

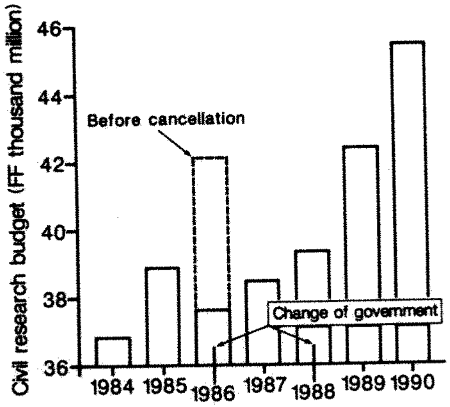
The present period is one of renewed growth after the cutbacks between 1986 and 1988, but the French research budget is only just finding a character of its own. State research spending, and how this is reflected at the laboratory bench, still bears the imprint of the exuberant policies of the young Socialist government elected in 1981 and then the sober pruning of a neo-Gaullist government that held office for two years from 1986.

But the tone of the decade as a whole is undeniably that set by the Socialist government formed by the newly elected president, François Mitterrand. In 1981, his new Minister for Research and Industry, Jean-Pierre Chevènement, organized a series of now historic colloquia (*assizes*) to help determine the shape of research policy, spawning radical initiatives that found their way onto the statute book in the 15 July 1982 law on the orientation and programming of science and technology research.

The government declared that civil research spending should rise to 2.5 per cent of GDP (gross domestic product) by 1985. To that end, the 1982 statute committed the government to increase the civil research budget by a remarkable average of 17.8 per cent a year and to increase the number of state-supported researchers by 4.5 per cent each year until 1985.

In 1983, Hubert Curien, the present Minister for Research and Technology (see next page) took over from Chevènement, and innovatory schemes were announced to encourage technological progress. A tax incentive scheme to promote industrial research was set up with the goal that, by 1985, industry should contribute 1.5 per cent of GDP to research and development.

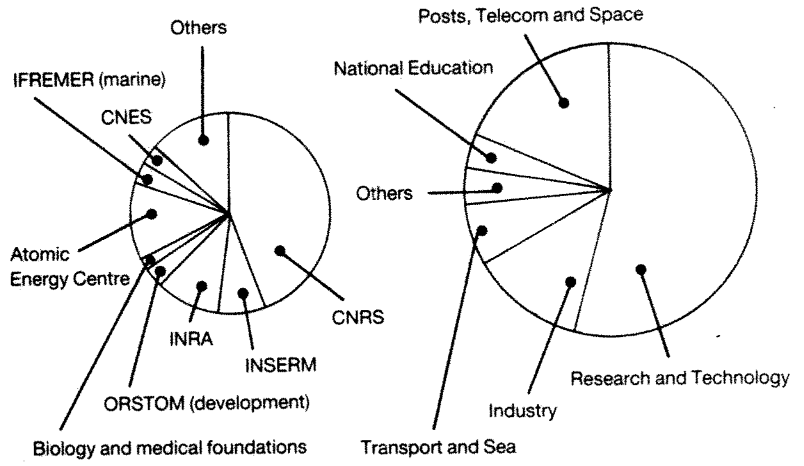
EUREKA, the now highly successful European Communities initiative to promote trans-frontier collaboration in high-technology industry, was proposed in 1985 by Mitterrand, but it was Curien's brainchild.



It would be facile to say that this early period was uniquely good and that it came to a sudden stop when, in March 1986, the Socialists lost power. (Mitterrand remained as president, during an uneasy spell of what was called cohabitation.) But the neo-Gaullist government led by Jacques Chirac sought above all to curb public spending and to encourage the private sector to carry more of the burden of research support. The 1986 budget was annulled and the budgets of the large research organizations, such as CNRS and INSERM, virtually frozen.

Whatever the economic merits of the Chirac government's drive to streamline what it regarded as a costly and overweight public sector, those were lean years for state-supported basic research. CNRS, long regarded as a hive of left-wing trade unionists which had become too large and too powerful, was at the centre of a maelstrom.

The ministries for research and for higher education were merged under Alain Devaquet who, with encouragement from conservatives inside and outside government, launched a plan to reform CNRS. But this failed, leaving the research council's affairs in turmoil for over a year.



The Research and Technology Ministry receives just over half of the government's civil research budget (right). The CNRS and its institutes dominates the ministry's budget (left).

Devaquet resigned and was replaced by Jacques Valade, but with a much-diminished ministry; most of the budget had been handed to the minister for industry. In the event, Valade achieved little; his appointment was followed by elections which, in 1988, brought the Socialists back to power, with Michel Rocard as Prime Minister and Hubert Curien once again in charge of research.

After a short period when higher education and research were lumped together, Curien was given his own ministry of research and technology from December 1988. The civil research budget, which groups together state finance from all ministries, was reinstated — and the Chirac government was accused of budgetary deception, using defence spending to mask a fall in civil funding.

With Mitterrand once again declaring research and education national priorities, Curien was able to inject FF830 million into the research budget immediately to offset the cuts of his predecessor. The 1989 budget was up by 7.6 per cent, recruitment began again and, in the 1990 budget, salaries were improved.

But the growth in the public sector is more like half that of the pre-1985 period. Furthermore, Curien has made it clear that he wants to encourage both basic and applied research, but that big organizations such as the CNRS must run a tighter ship. A committee for evaluation has been set up and plans to 'modernize' the CNRS are under way.

At the research bench, all is not rosy. With inflation running at 3 per cent a year, the 7.3 per cent increase of the 1990 budget amounts to a more modest 4.3 per cent in real terms. The figure is even less when costly space and aeronautics, which were given a special boost, are subtracted. And, because the number of researchers has continued to rise throughout the decade, but faster than budget increases, the average scientist's research money buys almost 20 per cent less than ten years ago.

Yet the present government has not wavered in its objectives. It wants to make sure that France is well placed for the year 2000. And it now aims to see national civil research spending — hovering around 2.3 per cent of GDP — rise to 3 per cent.

Peter Coles

SEARCH MINISTER

Curien weaves beguiling web

M. Hubert Curien is an unassuming, almost shy, man with the qualities of a terrier. He was summoned from his post as director of the Centre Nationale d'Etudes Spatiales (CNES) to superintend French civil science on the break-up of Chevènement's ministry of industry and research in 1983. During the Chirac interlude (1986–88), he was elected president of the European Science Foundation, but then summoned back to Paris as minister of research and technology when the Socialist party was returned to power.

Curien believes that French science has, indeed, become stronger over the past decade, partly at least because of his government's willingness to spend money on research. But he insists that research had not been neglected in earlier decades. One subtle change, he believes, is that the French are now proud of their research institutions. In the old days, "we were proud of M. Pasteur, not of the Institut Pasteur."

Links between basic research and industry have also been strengthened, partly at least because of the government's willingness to support (through, for example, CNRS joint projects on a 50:50 basis. Curien is pleased with the way in which CNRS has functioned as a focus for these activities. The interaction has also encouraged French companies to spend more on applied research. "If we had not done this, we should have achieved nothing", Curien says.

Unassuming terrier Hubert Curien.

Another striking feature of the past decade has been the steady internationalization of science — "it's now a real thing". He believes that French science has benefited powerfully from the impetus that has driven individuals into international collaborations.

He notes that French research groups profit greatly from the relatively small sums available from the European Commission, whose spending on research has grown to 4 per cent of total European spending on research.

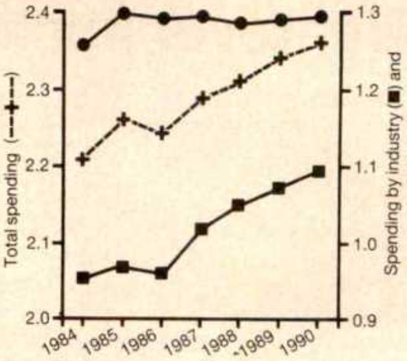
Curien also acknowledges that problems remain. One is mobility or, rather, the lack of it: people tend to stick in the same laboratory or other institution for too long. The concentration on Paris, around which something like a half of all French scientists work, is another.

But except for the salaries of beginning scientists at public laboratories, and the bottleneck in promotion in the middle ranks (which he is trying to widen), Curien is not too worried about the general unflattering comparison between salaries in the public laboratories and elsewhere. "If industry took more good people out of CNRS, I would be happy."

On the general opinion that France needs a substantial scheme of postdoctoral fellowships for its own nationals, he is ambivalent. He acknowledges that postdoctoral fellowships would encourage mobility within the network of government laboratories. Such positions would also help to improve teaching and research at the universities. But, like many others, he is impressed by the experience of 1969, when the then government agreed with the demands of trade unions that postdoctoral fellows of longstanding should be given permanent positions. "That", Curien says, "was a catastrophe."

Curien's position is powerful because his ministry is powerfully placed at the centre of the scheme of things. Other ministries (except defence) must say what they spend each year, and how. This enables him not merely to shape the general balance of research activity but also to back small-scale initiatives. A few months ago, for example, he was putting his weight behind a scheme due to Jean-Pierre Changeux, professor at the Institut Pasteur, for marrying French neurobiology with mathematical studies of the properties of neural networks; according to Changeux, he had mentioned the goal to Curien at a chance meeting. And about now, Curien will be giving a final opinion on an attempt to define French involvement in the Human Genome Project. (Many influential people are now less cool than previously.)

Others of Curien's schemes are less particular. Thus he began a programme (now costing more than FF1,000 million a year) enabling intending researchers, many of them industrial engineers, to write PhD theses by means of a three-cornered partnership with a public or university laboratory and a company. More recently, he has set up a national committee for the systematic evaluation of French science and technology, which in turn has spawned a small unit called l'Observatoire des Sciences et des Techniques, bent on the development of indices of performance.



Figures (% GDP) reveal that industry takes the credit for much of the recent increase in spending on research.

Yet one of the ministry's goals remains beyond Curien's reach. It has long been the Socialist government's view that research spending should amount to 3 per cent of GDP, putting France on a par with West Germany, the United States and Japan. This year, the percentage is 2.38 per cent (see figure). The ministry blames the shortfall on France's industrial enterprises, whose spending on research has grown, but not as quickly as the government asks. But the figure shows that it is the government's spending that has stagnated, as a percentage of GDP, at just under 1.30 per cent.

But Curien's ministry does more than merely administer science and technology; it is one of the chief means of persuading France's taxpayers (other than those who get tax credits for research spending) that science and technology are good for them.

Pride of France: the Pasteur has at last ousted Pasteur in the scientific hierarchy.

Thus a recent popular (and handsome) booklet on French science under the title "A new impetus (*élan*) for research" echoes the president of France, François Mitterrand, by declaring that its goal is to "make research a national priority". Research, it declares, "is at the heart of the development of modern societies. . .". Research will enable France to "meet the challenges with which the national economy will be confronted in the global market" and to "keep its place among the principal industrial powers of the planet".

Nobody at the research ministry is shy of this rhetoric, which everybody believes. And, of course, there are many in research who hold that the grand phrases are merely a statement of the obvious. But the French research ministry differs from comparable organizations elsewhere in taking such a a positive stand in favour of the ways in which it spends its budget funds. It is good for the morale of those who work in the ministry's dependent organizations, and may even have helped to cultivate the general French interest in all things new and technological. Curien, who is in no sense a salesman in the conventional mould, may have done more than he imagines to engender enthusiasm for French research. □

EMPLOYMENT

Working on the public payroll

One way or another, most French researchers work for the government. There are more than 22,000 of them (and 37,000 support staff) on the payrolls of the research councils and the other public organizations active in civil research. (The Commissariat à l'Energie Atomique or CEA, for example, employs more than 1,400 people on research as well as 4,000 on research support.) The numbers of qualified scientists and engineers at the universities may be even greater.

For what it is worth, employment in the public service is growing overall. This year, the research ministry estimates that 432 new posts in research have been created (offset by the loss of 31 posts at the CEA). This amounts to a growth of research posts of 1.9 per cent. The growth of support staff between 1989 and 1990 was roughly half as much.

Luckily, the members of this small army of people do not all behave as civil servants. The republican spirit, as well as the common name *chercheur*, gives them independence. Many are prepared to bite the hand that ultimately feeds them.

Otherwise, industrial research and development is a growing source of employment, as are international organizations as different as the Institut Laue Langevin at Grenoble (see page 137) and the Joint European Torus (the European Commission's thermonuclear fusion laboratory) at Culham in Britain. One also senses among French researchers a growing interest in working at public research laboratories elsewhere in Europe; the Max-Planck institutes are most often mentioned.

In France itself, there is also a handful of institutions which, while largely supported by government funds, enjoy an exceptional degree of autonomy acquired either by tradition or by access to an independent source of funds. One obvious example is the Collège de France, created in 1530 by the then monarch François I to enable him to keep up with the scholarship of the Renaissance, and which is now a means by which outstanding researchers can both redouble their efforts (by setting up extra research groups) and supplement the high-level teaching provided by the universities of Paris. Another is the Institut Pasteur, founded by Louis Pasteur with the profits of his vaccine business in the nineteenth century. (The Pasteur's smaller and less well-known cousin at Lille, with its special interest in tropical diseases, is a far from negligible institution.)

Salaries are more or less uniform throughout the research organizations, but may be supplemented (to a degree widely considered as "unimportant", often "derisory") by part-time university teaching. The present salary structure in CNRS strongly emphasizes the importance of the promotion barriers in the determination of researchers' well-being.

So the research ministry had promised a three-year promotion plan that will loosen the structure. Beginning in 1991, those who have spent four years on the lowest rung of the research ladder (in the grade *chargé de recherche de deuxième classe*, or CR1), will be promoted to CR1 against evidence of their competence in research. The budget for the current year also allows for a shift in the balance between the three senior and two junior research grades, the effect of which will be to replace 462 CR2 research posts by a similar number in the senior grades (DR1, DR2 and DRE, where DR means "*directeur de recherche*" and E stands for "*exceptionel*").

There are similar proposals for improving the promotion prospects of support staff, so that an extra FF120million is spent on salaries this year. Yet the employment of support staff is a widespread headache for laboratory directors. Even secretarial jobs must be filled competitively, by *concours*. Technician-engineers are usually able to do better for themselves in commercial industry than in the public service. Computer experts are almost impossible to recruit on the salary scales on offer, with the consequence that many researchers are reconciled to writing their own computer programs (while others skew their industrial collaborations so as to get help of this kind). □

ORGANIZATIONS

Playing the name game

Acronymism has become part of French culture, the influence of the Académie Française on the language notwithstanding. Prudent organizations publish lists showing what the acronymic names for their dependent units mean. What follows is a guide to the principal French research agencies and their dependent parts.

Organizations in France quickly acquire a life of their own. To create a new organization within the public service is no easy matter: the whole government has a say, and the Council of Ministers must approve. But once created, an organization cannot easily be dissolved. Both the bureaucracy and the unions will use their influence in the interests of permanence.

The Centre National de la Recherche Scientifique (CNRS), which celebrated its fiftieth anniversary last year, is the oldest and the largest. Its purpose is the conduct and encouragement of basic research in the whole of science. To that end, it employs 26,000 people, more than 11,000 of them researchers. Its public subvention in the current year is FF10,330 million, up 6.9 per cent from the previous year.

INSERM stands for Institut National de la Santé et de la Recherche Médicale and operates on a scale roughly one-sixth that of CNRS. The current budget (FF1,830 million, up 5.6 per cent from 1989) allows the employment of more than 1,900 researchers. Many of INSERM's research units are free-standing laboratories, more often (as at Lyon, for example) sited near hospital complexes than university student campuses. The interests of these two research councils deliberately overlap. CNRS takes the whole of research for its canvas, but there are several joint CNRS/INSERM research units.

INRA (for Institut National de la Recherche Agronomique) will cost the research ministry FF2,450 million this year (an increase of 5.0 per cent). Its operations are more self-contained than those of CNRS and INSERM, both of which are increasingly dependent for research funds on partnerships with other agencies and industrial organizations. Its 1,670 researchers are only one-sixth of its total manpower, reflecting INRA's role in providing agricultural extension services. □

CREDITS

Money oils the wheels

SINCE 1983, France has offered industrial and commercial enterprises an abatement of their tax bills on account of the research they carry out or otherwise support, but on a formula devised by Jean-Pierre Chevènement that must often seem a little like that of the mediaeval torture apparatus called the rack. The tax credit is calculated not on the basis of what enterprises spend in the relevant year, but on the extent to which their research spending has increased from one year to the next.

How well has the system worked? A study last year by two industrialists (Jean Cantacouzene, director of research at the oil-company Total, and Pascal Gendreau, joint director-general of the government organization for small and middle-sized business) has shown that the system at least provides a means by which the government can get to learn of the changing pattern of research in different kinds of industries.

One surprising finding is that tax credits tend to be a larger proportion of total research spending in traditional industries, such as furniture and textile manufacture and in food processing, than in high-technology industries, no doubt because the companies choosing to register for credits now have only recently embarked on such research.

The system is also cunningly biased against large enterprises. Of 346 companies with turnover exceeding FF500 million applying for tax credits in 1987, the credits eventually awarded amounted to only 2.5 per cent of total research spending, compared with 12.8 per cent for the 3,682 companies with a turnover of less than FF500 million. It also seems that the smaller businesses constitute the fastest growing of the tax authorities' applicants, suggesting that the scheme serves its purpose of spreading the research culture.

The figures brought to light by the tax-credit scheme are part of the basis for the government's assertion that French industry is still spending less on research and development than it should be. The report of the Cantacouzene-Gendreau study concludes that industrial research is some 0.5 per cent of GDP less than it should be if France is to keep up with West Germany and Japan in relative terms. That deficit amounts to FF25,000 million a year at present.

Overall, the numbers of companies benefiting from the tax credit system multiplied fivefold between 1983 and 1989, to an estimated 7,000 (the returns are not yet complete). The cost to the Treasury is estimated to have been FF2,600 million last year — but the cost of administering the system is said to have been "derisory".

For the future, it seems to be agreed that the scheme should be given more publicity, and that the government should agree to make it permanent. Already it has been conceded that companies making substantial research expenditures in a single year should be able to spread the funds over several years. ☐

INDUSTRIAL RESEARCH

Can government back winners?

FRANCE has taken a long hard look at Japan's success, and wishes it could follow suit. But, with French industry not willing to shoulder the responsibility for spending what it might, the government has become the initiator of last resort.

That seems to be the philosophy on which the French government is now working, and the explanation for the substantial support for industrial research over the past two years. Between them, the research and the industry ministries will this year spend about FF5,000 million on industrial research of a general character, quite apart from the best part of FF6,000 million spent on research at the CEA and other mission-orientated research organizations concerned with space, aeronautics and the like. The largest single increase in the research ministry's budget for the present year — 30 per cent — takes its general fund for industrial research to FF1,565 million.

There have always been hankerings in that direction. The legend of the French nuclear energy industry began that way, with a deliberate decision to found a new industry with research and development. Did not France also invent EUREKA (in 1983) as a way of persuading other European states to invest funds in high technology?

Research minister Hubert Curien leaves no room for doubt that the sponsorship of industrial research is his priority for 1990, as it has been for the past two years. The emphasis will be on the search for new products and processes, to which the ministry expects to commit FF300 million this year, on perhaps 40 projects. The chosen fields are in new materials and food technology and biotechnology.

Two other goals have high priority, of which the more ambitious is that France should make a mark in the development of high-definition television (HDTV). It is only a small part of the calculation that France itself is likely to be a natural market for devices that bring the clarity of the cinema-screen into every living room.

More relevant to the choice of this priority is France's conception of itself as Europe's research strategist. There have been several occasions in the past 30 years when France has invested its own funds in huge technical projects it could not hope to carry through on its own, in competition with other players on the international markets, but which have been strategically important for Europe.

Nuclear energy is such a case. Although there has been a brief pause in French reactor construction (see page 139), if — some would say when — there should be a revival of demand for nuclear generating capacity in Europe, French nuclear contractors may be better placed than others to win orders from European utilities.

Much the same has happened in aeronautics and space launching, where French investment in research has been used (together with political persuasion) to prompt the formation of international companies that manufacture civil aircraft and offer space launching facilities (Airbus Industrie and Arianespace respectively). In each case, the objective has been to create a European counterpoise to a *de facto* US monopoly.

French support for HDTV is, rather, directed eastwards. From the outset of the EUREKA scheme, several projects have been directed at the processing of digital representations of video images, the basis of schemes for radically improving video definition. Non-French companies such as Siemens (West Germany) and Philips (Netherlands) have been closely involved from the beginning. But nobody should be surprised if official French enthusiasm for HDTV — the EUREKA rules allow governments to contribute towards companies' research expenses — culminates in a proposal for a joint European venture to head off the Sony's of this world.

The processing of silicon wafers is the research ministry's other immediate goal. The code-name is JESSI (for Joint European Submicron Silicon). The immediate goal is to make a 1-Gbyte memory chip, but the hidden agenda might be to make a *super*computer on a single chip. Modest Hubert Curien's ministry will acquire clout (perhaps even kudos) if the enterprise succeeds because of its ability (relative to that of comparable European ministries) to urge its client companies towards investment by offering (sometimes threatening) to spend its own money.

For the rest, the ministry plans to concentrate on small and middle-sized companies, traditionally cared for by a state agency called ANVAR (for Agence National de Valorisation de la Recherche), whose budget has been increased by 10 per cent this year. It will be interesting to see, a year from now, how many of those intermediate companies are in the business of high technology. The guess of 100 per cent will not be far from the mark. ☐

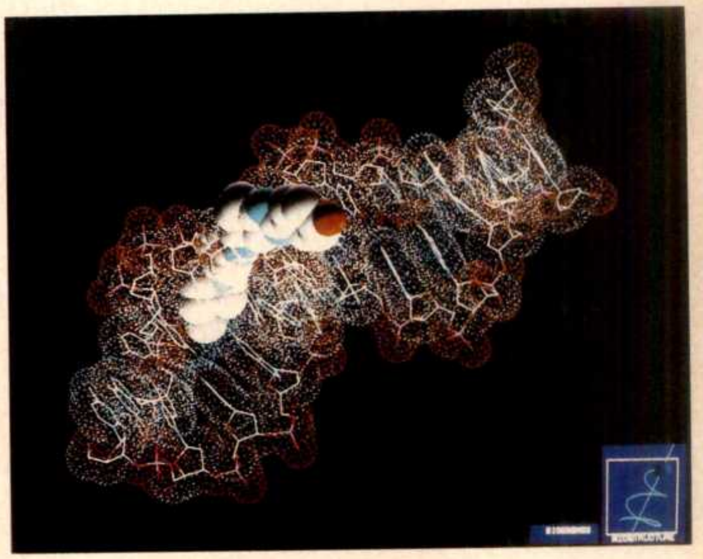
JOIN THE LEADERS

In fields such as chemistry, pharmacology and biotechnology, both the economical and technological stakes are increasingly important, resulting in an all the more fierce international competition.

At the heart of the debate : biopolymer engineering and the creation of new molecules.

To become the leader, you have to increase productivity, creativity and efficiency continuously. For this purpose, new and powerful computer tools exist.

BIO-GROMOS, a molecular modeling and simulation software constitutes one of them.



Designed by **BIOSTRUCTURE, BIO-GROMOS** constitutes a great asset to the **R & D** departments involved in research projects, such as:

- refinement of structures from **NMR** or cristallographic data,
- conformational analysis of organic molecules and biological macromolecules within the context of "drug design",
- simulation of the effects of the peptidic models' directed mutagenesis.

BIO-GROMOS integrates the **GROMOS** functionalities - the most powerful molecular simulation package -, user-friendly graphical visualization tools and molecular building modules. It is also supported today by a most qualified scientific team.

BIO GROMOS is the turnkey solution for the design of tomorrow's active molecules.

Biostim
8 comprimés enrobés dosés à 1 mg
Laboratoires Cassenne
3, Square Desaix 75015 - Paris

Form and presentation. Coated tablets (white) in blister packing; box of eight. Ingredients. Weight of ingredients 1 mg. Weight per box 8 mg. Glycoproteins extracted from Klebsiella pneumoniae retained on a membrane of average porosity 0.011 micrometres and expressed in anhydrous product. Excipient; lactose, corn starch, polyvidon, magnesium stearate, cellulose acetylphtalate, sacharrose dibutylphtalate, sodium carboxymethylcellulose, colloidal silicium, talcum, polysorbate 80, titanium dioxide, cireolanche q. s. p. per 400mg tablet. Properties. (cp. monograph by Vidal) BIOSTIM is an immunostimulant. Tests have shown it to reactivate all three levels of defense against infection (phagocytosis, humoral reactions, reaction to cellular mediation). BIOSTIM, by reactivating the immune system, has been shown in tests to protect against bacterial or viral infection whether it be intra or extra-cellular in development. This action has been demonstrated in both the normal and the immuno-depressed animal. The effectiveness of annual treatment by BIOSTIM has been established, through controlled double blind tests against a placebo. Used for preventing chronic infections of the respiratory organs, BIOSTIM ensures: a reduction of the risk of subsequent reinfection; a shortening of attacks of bronchial infection. Directions. Adults: preventive treatment of chronic bronchial reinfection. Children: prophylactic treatment of chronically recurring respiratory infections (of at least two years or after tonsillectomy). Contra-indications. Children under one year. According to current knowledge, BIOSTIM should not be used with patients suffering from auto-immune diseases. Although no embryotoxic or teratogenous effects occurred during tests on animals, BIOSTIM, like all new treatment, is not recommended for pregnant women. Warning: Users are recommended not to exceed the stated dose: annual course of treatment of four boxes. Medication should not be used for prolonged periods. Directions for use and dosage. Swallow the tablets without chewing preferably in the morning before breakfast. Treatment: one course of treatment per month for 3 consecutive months, that is, first week of treatment: 2 tablets daily, stop for three weeks;

secon
of treatment: one table
stop for three weeks; third week o
ment: one tablet daily. Daily cost
francs. Annual cost: 174 F.A.M.M.

CNRS

To modernize and open up. . .

FRANÇOIS Kourilsky, the molecular biologist from Marseilles who is now director-general of CNRS, was appointed to his post by Hubert Curien in 1988 with firm instructions to "modernize and open up" CNRS. How well does he believe the task is going?

He is anxious that the organization should not be mistaken for the whole of French science, noting that it accounts for less than 19 per cent of the total civil budget. But he is pleased about the growing links with industry. At the latest count, industrial contracts with CNRS laboratories number 2,700, nearly two for each of the 1,300 distinct research units. Their total value is FF1,300 million, more than a tenth of the total budget. There is, he believes, a long way to go before the laboratories will be at a loss to know where next to sell their services.

Industrial contracts seem to serve a wider purpose than to keep the wolf from the door of some CNRS laboratories. To this outsider, one of the wider consequences has been to persuade industrial companies that there is, indeed, some benefit to be won from research and development.

Kourilsky says that, until recently, French industry has not significantly increased the numbers of people it employed on research and development. But now, he says, there is a surge in the recruitment of people, especially in fields such as mathematics, computer science, electronics and chemistry, not to mention molecular biology. Evidently he shares Curien's view that those who work for him should be doubly honoured if they leave to work in industry.

But is there a danger that the balance between contract work and basic research will be too much skewed against the latter? Not as things are, he holds. Perhaps the difficulties will arise when, as the volume of contract work continues to grow, but patchily, some laboratories will find themselves short of people for their core programmes while other, lacking contracts, will have people but only modest research funds.

Kourilsky agrees with Curien (see page 126) that the salaries of young researchers should be improved, but considers that the promotion bottlenecks are "still a problem".

On the scheme to provide university teachers with research funds through a committee within the education ministry, he holds that the source of funds should be independent of the university system. "On that, I diverge from Claude Allègre." The problem is that of evaluation. He regrets that the Napoleonic universities "lack independence".

CNRS differs from most comparable organizations in the large number (1,300) of laboratories in which its people are dispersed. The range is from a handful of people to some scores. So how are new laboratories started, and old laboratories disbanded?

As always, it is easier to start than to stop. The process of evaluation, Kourilsky believes, is accurate and reliable. But the law requires that a decision either to open or close a laboratory should be taken only on the basis of expert advice. The process can be slow.

On the future of the organization, he believes that links with universities will be strengthened, together with those with industry. But there are particular opportunities, he believes, in the emerging pattern of a single Europe for forming stronger links with overseas laboratories.

Kourilsky has not been at his job for long enough for his impact on CNRS to have become clear. Moving the bureaucracy will not be a simple task. But he seems to have one important augury on his side — a largely enthusiastic research force. □

BUDGET PRESSURE

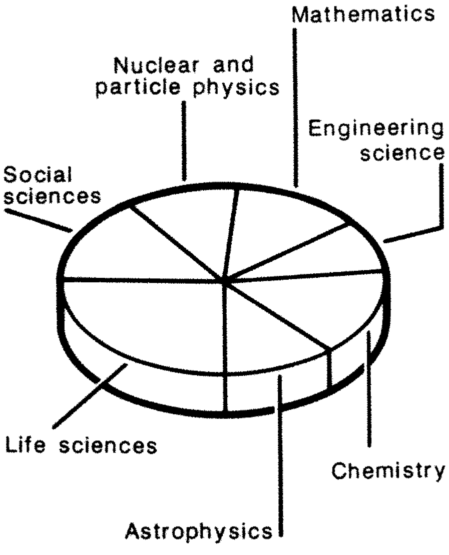
Staying ahead of the game

THE albatross around the neck of CNRS is the risk of being blamed for everything that goes wrong.

Although, on balance, CNRS attracts more praise than protest, the years ahead may be more difficult. The budget squeeze on CNRS's disposable expenditure is one source of strain. The need for some means of financing university research will be a further complication.

CNRS is potentially the more vulnerable because it has a finger in every pie. The existence of INSERM notwithstanding, for example, the life science division (one of seven) takes a quarter of the total budget. But CNRS is also strong in the humanities and social sciences. (The Science de l'Homme et de la Societé division takes more than 10 per cent — see figure below.)

Over the decades since the early 1960s, when it was common to find CNRS researchers working in isolation, and on a shoestring, in cubby-hole laboratories throughout the University of Paris, the organization has shown itself to be remarkably resilient and adaptable.



Distribution of CNRS funds between divisions, 1990.

The Chevènement upheaval of the early 1980s may nevertheless be one of the best things to have happened to CNRS, confirming its central place in the French scheme of things as well as the role to which it had already aspired of being one of the chief means of research planning in France.

The then-new director-general of CNRS, Pierre Papon, made forward planning his centrepiece. After an elaborate consultation within CNRS and industry, a score (literally 20) research themes were singled out for special attention, and became the basis for research planning in succeeding years. While the interest of the particular themes may since have been attenuated, the mechanism remains. CNRS is forever organizing consultations among interested groups to determine what weight should be given to particular themes.

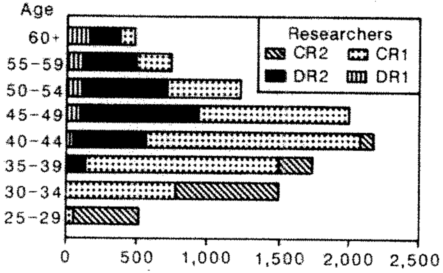
During the same period, the influence of CNRS on university research has been formalized and legitimized, by the device of associated (*associés*) laboratories, set up by means of formal contracts between universities and CNRS, and in which CNRS and university employees work side by side. (Other research organizations, such as INSERM and CEA, follow the same practice.) Between them, the research agencies have come to provide support — people as well as money — for most of the outstanding research at French universities. Throughout France, CNRS is this year supporting 1,003 research groups by this mechanism. (It also has 366 in-house research units, some of them very small.)

There is no shortage of academic research groups looking for support of this kind. By a curious device invented in 1982, the education ministry nominates (on the advice of CNRS) research groups considered deserving of outside support — *recommandé* is the designation — which may look for such crumbs as fall from the tables of CNRS and the other *grandes organismes* of research, perhaps end for full support. On one reckon- there are a further 1,000 of these earch groups waiting in the wings.

Now, as always, the snag is the budget. Despite the general growth of funds for research, the CNRS share of the civil budget has not grown as quickly as the whole. And the commitment of nearly 75 per cent of CNRS's share to the salaries of its employees means that its disposable income is shrinking. On one estimate, annual research expenses at CNRS account for FF110,000 a researcher, compared with FF180,000 at INRA and FF215,000 at INSERM (the best heeled of the research-support organizations).

CNRS seems bent on righting that imbalance. University research groups, especially the *recommandés*, were chilled at the end of last year when Kourilsky (see previous page) remarked that "CNRS does not have the means to support all university research groups" even when they are excellent. That sharpens the dispute over the education ministry's plan to provide research funds direct, but it also requires that CNRS itself should choose between being the daring cat that steals the cream from the top of the milk and being the pillar of the establishment it has become used to being.

That is for the years ahead. Meanwhile, CNRS has kept its options open. The organization is typified by its post-Second-World-War headquarters at Gif-sur-Yvette, in the suburbs southwest of Paris. The 'campus' is a park, acquired cheaply in a deal that requires CNRS to keep a team of gardeners on its books so as beautify the park. On one side is a fairly recent chateau (now a visitors' hostel) and, on the other, a collection of laboratories embodying the recent history of CNRS in bricks and concrete (mostly concrete from a less prosperous age). Despite the gardeners, the campus seems seedy.



Age-structure of CNRS research population, 1988.

What CNRS has been doing is plain enough: it has been following trends apparent elsewhere. Although nuclear and particle physics are still responsible for FF790 million, the proportion has fallen from 22 per cent in 1978 to 10.9 per cent in 1989. But life sciences, less than 18 per cent in 1978, are now 25.3 per cent (and employ more than 2,800 researchers at CNRS in-house and out-house units). Inevitably, the life sciences division of CNRS spends more of its budget on recurrent costs than on equipment and (less predictably) just about half of its total budget on associated and joint (with other councils) laboratories. In the first half of the 1980s, engineering sciences (especially computers) grew quickly — and the number of research posts virtually doubled — but now chemistry is the most quickly growing.

CNRS has also been ageing. In 1988, only 35 per cent of its researchers were younger than 40. Although the recruitment and promotion rates are now to be increased, it is difficult to see them quickly creating the bottom-heavy pyramidal age-structure one would expect to find in a research organization. No wonder that Curien (see page 126) says that he is glad that industry threatens to hire away senior people. ☐

RESEARCH CULTURE

A club-like atmosphere

THOSE who work for CNRS behave like members of a club because they are members of a club. To be a CNRS researcher is to be a member of a distinctive group, as if it were to be the French Navy or the *corps diplomatique*. But CNRS is, of course, not quite as grand.

The sense of club is easily explained: for at least the past decade, entrants to CNRS have won their places in the public service by competition in the common *concours*. They vividly appreciate the distinction between themselves (who are in) and those who are out. At least until recently, they could be reasonably sure that they would work permanently in this branch of the public service, with occasional postings elsewhere.

But this commonality does not engender a dull sense of uniformity. Different research laboratories have their own distinctive spirit. Some are plainly riding high, perhaps sustained by industrial contracts or grants for special projects. Others harbour a deep sense of neglect. They are inevitably the laboratories most oppressed by the bureaucracy of their parent, which is organized into seven divisions and no fewer than 36 sections, each with its own secretariat.

The underlying difficulty is the small proportion of the CNRS budget free for research expenses. More than 75 per cent of the budget is committed in advance to salaries; heat, light and maintenance take a substantial proportion of the rest. (INSERM seems better placed in this regard.)

Travel funds are not too hard to come by; most people acknowledge they can make one substantial overseas journey every year or two, while European Communities sources are increasingly used for travel within Europe. But the proportion of a laboratory's total budget remaining in a director's hands for research expenses may be relatively very small, perhaps less than 10 per cent of his salary bill.

Yet CNRS abounds with people who hold the highest opinions of their organization. For many, the sense of security and freedom they enjoy makes up for the gap between government and industrial salaries. One, the director of a laboratory at Gif-sur-Yvette, says that CNRS provides unique opportunities for research. Another gives it as his opinion that CNRS, whatever its faults, has become the dominant arbiter of quality in French science. The organization's willingness to enter into collaborations with universities and industrial companies, sometimes taking the initiative in forming them, is generally commended.

One British member of a joint CNRS/INSERM laboratory says that he is more settled, and more productive, in France than he had been at a British university. He reckons that the continuing shortage of academic positions in Britain must soon stimulate a soutwards stampede across the English Channel when British people realize that, at the outset, all the French they need is that required to keep body and soul together.

Another Briton at another laboratory, fresh from a postdoctoral position in the United States and with an enviable reputation for the development of a new technique, says that he chose the CNRS laboratory from among half a dozen at which he had been offered a position. (Sybaritic considerations seem to have played a part in the decision.) Testimonials of this kind abound. Because, to paraphrase *Anna Karenina*, contented employees are all alike, but discontented employees differ in their discontent. The following complaints against the organization are necessarily more voluminous. Their balance should not be judged by the space they occupy.

First, there are problems about people. Laboratories not well-endowed with outside funds are less able than others to keep competent young people at work while they compete for permanent places at successive *concours* for permanent positions. The result, some say, is that able people are often lost to the system at the beginning of their careers.

Filling vacancies is a constant headache. If a vacancy should arise, even among the technical or administrative staff, it cannot automatically be filled. Instead, the section or even division to which the laboratory belongs will at least consider whether the vacancy should instead be awarded to some other unit. According to at least one director, there are no mechanisms for appointing even junior staff on a temporary basis; either a public servant, or nothing.

There are recurring problems about research allocations. Laboratory chiefs are usually told, in the February of the year to which the information applies, what their allocation of funds will be. One CNRS director says that last year, after his budget had been cut by 30 per cent with no explanation, it took him until November to get the cut restored. (Luckily, the rules do not require that funds should be fully spent in the year for which they are intended.)

The need to make visits to Paris regularly, either as a member of an advisory committee (which is essential for staying in the swim) or to lobby against some particular injustice, is particularly irksome for those who live and work elsewhere. Reimbursement for the cost of doing so, as for other expenses legitimately incurred on CNRS business, is generally agreed to take months. One researcher says that he expects that CNRS will at any stage owe him FF20,000, or a month's salary.

Although many CNRS laboratories on university campuses enjoy the respect of and a good deal of influence with the associated universities, others lead a precarious existence there. One such group has been required to move its laboratory several times in the past seven years to suit the convenience of the university, and is now threatened with another move in October.

The most serious of the complaints against CNRS is that at least some laboratories appear to be inadequately informed of the overall policies that determine their affairs. This seems a shame when the people concerned are every bit as full of enthusiasm for their work as the general run of people working in CNRS laboratories. ☐

PLANT SCIENCE

Hungarian sowing seeds

THE Institut des Sciences Vegétales at Gif-sur-Yvette differs from others in the park in that it is brand new and that its director, Adam Kondorosi, is newly arrived, with his wife and co-worker, from Hungary.

The refurbished laboratory is that previously occupied by the teams who danced attendance on Gif's giant phytotrons, which were in the 1960s proof of CNRS's promise to botanists that they are deserving of large equipment as are nuclear physicists. The phytotrons have now been dismatled and the laboratory disbanded.

Kondorosi has been commuting between Gif and Szeged in Hungary for the past 18 months, while recruiting people for the laboratory. His appearence, more or less permanently, in this Paris suburb justifies earlier fears in Hungary that liberalization would entail the loss of able people (see *Nature* **344**, 611; 12 April 1990).

Kondorosi says that he is enjoying himself enormously, but that whether he will stay for good depends as much on his wife's inclinations as his own. Meanwhile, he says that he has continuing responsibilities at Szeged, mostly for the continuation of his research with graduate students, so that he will have to make occasional visits. CNRS seems compliant.

For the rest, Kondorosi's tale is an illustration of how CNRS (in this case with some help from INRA) sets about founding a new institute. The impetus was the conviction that the molecular and cell biology of plants would have important applications in agriculture. An international committee spent some months head-hunting for a director until it found Kondorosi (he rattles off the names of those who turned down the job). Now the objective is to recruit a team of people, perhaps internationally, to staff the five research groups whose work will stamp the laboratory's programme (and whose heads are already in place). The hope is to build up to between 60 and 80 people in four years.

One distinctive feature of the programme is that external collaboration is to be built in from the outset. Kondorosi says there are already agreements with the Max-Planck Institute at Köln and the department of molecular biology at Rome, not to mention his old institute in Hungary. He is also planning to work closely with the complementary CNRS institute at Toulouse, and is hoping for further support from the European Communities and from the European Molecular Biology Organization.

Kondorosi's own field is the study of how the symbiosis of rhizobia and plant roots is reflected in and mediated by the reciprocal exchange of chemical signals between them, which is one leg of the institute's programme. Another group will aim at similar understanding by more classical studies of the hairy-root syndrome (a variant of crown gall disease). There are also groups concerned with plant cell signalling (by means of auxin), the mechanism of damage by plant viruses and the molecular genetics of *Arabidopsis* — the eukaryotic plant with the smallest genome so far recognized.

Like other up-and-coming CNRS laboratories, the new plant sciences institute is already embarking on graduate education. Five or six students seeking the DEA diploma (a pre-PhD qualification — see page 122) have already been accepted for next year. Kondorosi expects that university relations will be simplified because two of his group leaders are also university professors.

But will there be enough teachers for them? Kondorosi says he has already advertised 18 vacant positions at the institute. There can hardly be a quicker way for someone from Eastern Europe to learn the ways of the competitive West than he has chosen. ☐

DEVOLUTION

Regional consuls in the wings

MME Katherine Piquet-Gauthier is the new regional delegate of CNRS at Montpellier, with responsibility for CNRS affairs in Languedoc-Rousillon in the south-west of France. She is one of a dozen people appointed last May, under the terms of a decree promulgated by CNRS last December, to offer regional groupings of laboratories with a more immediate presence than Paris can provide. But it is not yet clear how far administrative devolution will go.

The twelve regions and the sites of CNRS's regional offices are Alsace (Strasbourg), Aquitaine and Poitou-Charentes (Bordoaux), Brittany and Loire (Rennes), Limousin (Orleans), Ile de France (see below), Langeudoc-Roussillon (Montpellier), Lorraine-Ardennes (Nancy), Midi-Pyranees (Toulouse), Normandy (Caen), Provence-Côte d'Azur (Marseille) and Rhône-Alpes (Lyon). The administrative centre for the Pas de Calais region had not last month been chosen.

Many of the regional directors have not yet taken up their posts. The arrangements for the Ile de France (greater Paris) are complicated by the great concentration of CNRS responsibilities in the region, with the result that there will be five sub-regional directors working through a central office. Similarly, there will be two sub-offices in the Rhône-Alpes region catering separately for Lyon and Grenoble.

What will the regional offices and their directors be able to accomplish? Laboratory directors and researchers have a variety of aspirations for the new arrangements. Those who labour under a sense of neglect hope the new arrangements will give them a stronger voice in Paris. More immediately, there is also the prospect that the regional offices will simplify the bureaucratic structure (although some fear that their influence may be in the other direction).

On the question of whether devolution will make it easier to pay people's legitimate travelling expenses more quickly, Mme Piquet-Gauthier says "not yet, but wait and see whyat it's like when you're here next". ☐

ALUATION

RS reflects with pleasure

RS, which is always evaluating other ople, has recently been evaluating self. But the result is not so much a critical appraisal of the largest single research programme in France, as a kind of guidebook to science in general. The report of the evaluation is dominated by the theme of the growth of interdisciplinary research requiring multidisciplinary teams.

The self-evaluation, the report of which has just been published as *Rapport de Conjoncture*, has been prepared by 22 commissions established to evaluate themes singled out by CNRS for study, and ranging from Earth and Solar System to order and chaos and the transformation of societies. Readers must be prepared to look between the lines for outright self-criticism.

But one general theme is the emergence of a number of interdisciplinary problems to which French science should pay attention. One singled out for discussion is that of global change, but the study also notes that the properties of neurons promise to be of great importance in computer sciences as well as in physics and mathematics.

This colours the report's opinion of present arrangements for the training and recruitment of young people into science. It argues that there is a need to improve and increase the training of doctoral students to ensure a sufficient supply of researchers and university teachers. But doctoral training should also prepare young researchers for working alongside people of other disciplines. The report asks that something should be done to improve the public image of certain disciplines, citing mathematics (surprisingly) and chemistry as being unpopular.

On interdisciplinary research, most conspicuously at present represented in CNRS by four named research programmes (in materials science, energy, environment and technlogy at the workplace), the evaluation draws attention to some of the problems faced by those engaged on them, in particular by the risk that work on interdisciplinary problems may complicate the two-year evaluation of their research achievements by one or other of the 49 subcommissions, are responsible for this work. The report argues that people's willingness to work on interdisciplinary projects should be regarded, *a priori*, as favourable for their careers.

Of the international connections of French research, the evaluation acknowledges that English has now become the language of communication in international science, but says that there remains room for French on the national scene and in relations with francophone countries.

In general, the evaluation says, it has taken an optimistic view of the place of French science on the international stage, but it acknowledges that there may be a bias in the process of evaluation — research that is inherently good will be well spoken of, while that which is bad will leave little impression on outside critics.

The document acknowledges frankly that international collaboration entails the risk that researchers will be lost to France by means of a "brain drain" which is not confined to France. But it says that French collaboration in large international projects has an effect "at once dynamic and stabilizing". It says that the involvement of French researchers in overseas laboratories, and visits of overseas researchers to France, but particularly the exchange of scientists within Europe, "must be one of the keys to our successful development".

SUPPLEMENTARY INCOME

Living better by one's wits

The Napoleonic centre, it appears, can be flexible enough when there is cash to be saved. That seems to be why every laboratory in the public service seems to have a freebooter's licence to strike a deal on research with some third party, within the limits of a framework agreement. So laboratory directors at CNRS and others of *grandes organismes* have become entrepreneurs of a kind.

The results have often been spectacular. In some CNRS divisions, external support may be as much as a third of the total. Other ministries and public agencies provide more than half of this extra money, for projects as different as the provision of special research equipment and for research projects with a bearing on some development by a still nationalized industry — the High-Speed Train, for example. But particle and nuclear physics and the life sciences are almost exclusively financed out of CNRS funds.

It is also striking that France derives a substantial research support from international sources — in 1987, this amounted to 17.9 per cent of CNRS's disposable income, exactly the value of research contracts with industry. The European Community is a particularly important source of funds, both because participation in the major European research programmes carries public researchers into joint projects with industrial researchers and because the much smaller sums available for occasional travel from Community sources valuably supplement what CNRS can spend. ☐

Some rights and wrongs

Among the points made in CNRS's evaluation of itself are the following:

French groups have played an important part in the development of **particle detectors** at CERN and DESY since the success with Gargamelle in 1973, but steps should be taken to build on the experience of constructing the LEP injector at Orsay. Building a **4 GeV** electron accelerator, "no doubt in a European context", would allow important work with high-energy photons in **nuclear physics**. New instruments, in Hawaii and Chile will be followed by the Very Large Telescope (four linked 8-metre telescopes) being built by the European Southern Observatory, but French **astronomy** should be primarily concerned with the supply of theoreticians.

More generally, the subcommission on these topics expressed concern at the difficulty of preparing graduate students both theoretically and with a capacity to tackle unknown problems, with the "linear" careers of young researchers and with the continuing shortage of research funds.

The mathematics evaluation says the French **mathematics** school is "probably one of the best in the world" (which, by general consent, is fair). There are up to 2,500 mathematicians at universities, with only a tenth as many at CNRS. Now, the evaluation says, CNRS should be employing more mathematicians who are, it is said, less and less easily classified as "pure" and "applied". By way of proof, the evaluation draws attention to the invention, by engineer Jean Morlet, of the concept of wavelets (*ondelettes*, or convolutions of periodic and gaussian function as sets of elementary functions in which seismic signals can be expressed.)

Surface research is crucial in, for example, the electronics industry, and "France is now well-placed" by the provision of national facilities by collaboration between government agencies and industry. But the advantage could be in hazard because of the shortage of CNRS funds for medium sized equipment, while the immobility of people makes the development of effective research groups difficult.

In *informatique*, France is said to be strongest on the theoretical side and in the development of languages, while Japanese and US industrial laboratories dominate such fields as the development of an **optical computer**. Yet in both respects, the evaluation says that European collaborative programmes have a crucial role. CNRS is said not to have increased its numbers of specialists in these fields sufficiently. ☐

UNIVERSITY REFORM

A search for *égalité* in diversity

Claude Allègre, the bluntly spoken geophysicist who was director of the Institut du Physique du Globe at Paris VI until two years ago, could make his name with the quiet revolution in higher education on which he is now engaged. Or he could lose his academic friends.

Allègre, energetic and at once ambitious and impatient, has become director of higher education at the Ministère de l'Education Nationale (and de la Jeunesse at des Sports). But he keeps his hand in at the institute. He teaches a course and spends time in the laboratory. He hopes to manage every weekday morning next year. But even now he is working like a dog.

The task is herculean. By any standards, the university programme is calculated to astonish. In the academic year just ending, there have been 1.13 million students (or their equivalents as part-timers) at France's 76 universities, which means that 40 per cent of school-leavers at least begin on higher education. Allègre says that the ratio should be 60 per cent. "Then we shall be like the United States and Japan."

There is another driving force. The university system is what it is because of the student rebellion in the streets of Paris in the spring of 1968. Nobody forgets that the Left Bank was occupied by students for days on end. (Many of those same students are now, no doubt, civil servants.) Thus has been accepted the principle of open access: qualify in *le bac*, the popular name for the *baccalauréat*, the nationally standardized school-leaving examination, and there will be a place for you at a university. Naturally, the numbers grow.

Down to Earth: Allègre is keeping one foot in the university world.

So, inevitably, does the budget. In real terms (francs of constant value), spending on higher education has increased by 35 per cent since 1980, but half that increase has been squeezed into the past two years. The French government will have spent FF27,500 million (in present money) on higher education in the current year. Next year (the budget is just now being devised) it will no doubt spend more.

Allègre is not one to be dismayed by the immensity of his responsibility. He spells out the agenda. Build more universities (eight are planned, four in the greater Paris region called the Ile de France, four at places yet to be determined). Lift the spirits and the public reputation of academics by increasing the pay of able people, perhaps by 25 per cent. Recruit more graduate students, perhaps by offering them better stipends. Improve the quality of academic research by a system of competitive research grants administered by the ministry. Sign contracts with universities so that they can spend their budgets to the best advantage.

There are even plans to change *le bac*. Allègre is proud of a scheme to introduce students to chemistry by asking them to build molecular models; by the time they come to grapple with the laws of multiple proportions and the like, they will at least know what is meant by valency. There are also plans to introduce continuous assessment of students' performance in the awarding of *le bac*, if not in mathematics, then in other fields.

All this is meant to happen quietly. "We are making a revolution", but we say that "nothing much is happening". The more natural course would have been a "big new law", but that tendency is the "French disease", Allègre says.

Allègre does not hide from difficulties, but meets them head-on. Will not a system in which universities' activities are predetermined by a contract with the ministry mean that university freedom is curtailed even more than at present? On the contrary, says Allègre. Universities knowing what they want to do can negotiate an appropriate contract with the ministry, and then be more free than ever to pursue their goals.

He is passionate on this point, complaining that his republican compatriots have consistently failed to appreciate that diversity means *égalité*, and is not antithetical to it. The tendency has been to suppose that *égalité* requires that everybody should follow the same curriculum at the same kind of school. Emphasizing that the participation rate should be high (60 per cent) he says, "Look here, France is a Catholic country, and Jacobin and Napoleonic. . . in the end, the Catholic influence has won through."

Those are the forces in favour of uniformity and centralism. He acknowledges that universities as they are are too much alike. But freely negotiated contracts with the ministry could give universities the right and the opportunity to be different. The first negotiations with universities, in the west and south of France, are now under way within the framework of an elaborate set of parameters conjured by the ministry — 12 m^2 of space for a science·

ACADEMIC LIFE

A new vision or an old mirage?

Academics in France differ in their estimates of whether the government's new promises of support will materialize, but only because there are different degrees of scepticism. Most say, "We have heard all this before. We'll wait and see what happens." Many others will not wait.

What follows is honest reporting of academics' views adapted so as to conceal its sources, for reasons that should be obvious. (It matters less that academics are literally civil servants than that their senior colleagues can still powerfully influence their academic prospects.)

One group of 40 university teachers in literature — a group now responsible for the first-year education of 700 students — is asked (by the university administration) to take responsibility for 1,200 students. That would mean increasing the student to staff ratio from 20:1 to 30:1. There would be no extra teachers.

A teaching group of similar size, most of whose members applied for special contracts on the grounds of special expertise in teaching or research, has found that only two special contracts have so far been awarded. The recipients are both in their fifties, and are people of acknowledged distinction. One is so eccentric that he no longer teaches, and does not publish either.

There is a general complaint at the teaching loads of university professors; ten hours a week of lectures is commonplace. "That's impossible", says one professor at Paris VI. Such a load means that even the teaching must be skimped, while there is literally no time for research — and the funds for supporting research are steadily declining.

The position may be "even worse in Britain, but not in West Germany — there they seem to be spending money more intelligently". In France, there is a crisis. There are "not enough teachers, and those there are thinking of leaving", mostly for international organizations and industrial laboratories.

Other academics protest that the criteria for deciding promotion within the system are far from objective. A proposal that people's competence as researchers should be judged objectively, perhaps by publications records, was rejected by the ministry a year ago. ☐

, for example, but 3.5 m^2 for one in individual universities are making al claims in respect of extra things do.

The contracts, when negotiated, will run or four years which, a little to Allègre's delight, breaks the rule that ministries must not anticipate spending not yet voted by the National Assembly. (One guesses that the ministry's lawyers will deal easily with that subtlety.)

Allègre also agrees that French universities have been too conservative. Scornfully, he notes that molecular biology was taught at and by the Institut Pasteur long before it found its way into the curricula of the universities in Paris and that plate tectonics (his own field) remained in limbo for too long.

The ministry's mechanism for supporting university research is more controversial. Academics from all over France will compete for a share of a pot of money administered by a ministry committee, half of whose members are drawn from European countries other than France. Allègre is fighting for a 15 per cent increase of the funds available in the budget for 1991, now being drafted.

Might not a ministry committee assessing the quality of research proposals be tempted to use the funds at its disposal for solving other than research problems? Would not an independent grant-making agency be safer? Allègre does not agree. For one thing, the committee is international, but its subcommittees will also rely on CNRS assessments when making their decisions.

As proof that the system is working, Allègre notes that it has already drawn blood. "A lot of people are very upset — mediocre people and some universities." But he does not like the US system of competition for research grants; "indirect costs" are "ridiculous", as is the difficulty of finding support for long-term projects.

He is confident that "zero — nought" will be spent on "big programmes". But he would like to encourage research in innovative fields. He rattles off a string of topics — *informatique* in clinical medicine, molecular identification by physical means, cogniscience (the new name for neurobiology), the geophysics of the topmost 100 metres of the Earth's crust and the meteorology of cities.

So why, with these grand plans, does Allègre risk losing friends? Few will dispute the good sense of his ambitions. One worry is that the interventionist habits of the ministry will persist. More important (see below), there is a general fear that the funds for supporting Allègre's quiet revolution will be, as so often in the past, inadequate for the need and, perhaps, even hijacked by the pressing needs for general support in the university system. □

UNIVERSITY REFORM

On the way to open access

In the academic year just ending, there were 1.13 million students at French universities, an increase of 77,000 over last year. Next year, there will be more — just how many more will be known only when high-school students have been told the results of *le bac* this year.

For several years, the system has been growing at about 8 per cent a year. The mounting pressure of numbers is felt even in the highest reaches of the government — the official communiqué from the Council of Ministers (the French government's cabinet) announced that the building of 200,000 m^2 of extra space at universities had been sanctioned against the new academic year.

Since 1960, when there were a mere 215,000 students, the scale of French higher education has multiplied more than five times. The growth has been most rapid in the humanities, whose students account for more than a third of the total. Law and the *sciences économiques* (which include accountancy and management) account for more than 250,000 students. But in 1989 there were 192,000 students following courses in science and engineering, an increase of nearly a half since 1980.

As Mr Kingsley Amis would have predicted had he been French, more has meant worse. Faculties have not grown as quickly as student populations, so that ratios of teachers to students have generally declined. Harassed teachers at institutions other that the *grandes écoles* have been forced to skimp on research and scholarship as teaching and administrative burdens have increased. Who can wonder that many researchers in dedicated research laboratories scorn their nearest-neighbour academic colleagues? Or that, mostly for lack of suitable candidates, there were 2,000 vacant teaching posts in June 1988?

The pressure of numbers is greatest in the early years. Undergraduates follow a three-stage curriculum (the *premier*, *deuxième* and *troisième cycles*). The attrition rate at the end of the first cycle (for many, the end of the first year of studies) is high. For those who stay the course, the *troisième cycle* or fifth year is either a vocational course (such as the preparation for a career in teaching) or, in science fields, a preparation for research.

The education ministry is not for nothing the Ministry of National Education. It operates schemes for the national validation of degrees, the *licence* and *maître* qualifications of the first and second cycles in particular. Those with academic bent follow a course leading to a DEA (see page 122) qualification, previously a sufficient qualification for higher education work, possibly following that by embarking on a PhD thesis, lasting for two or three years.

The government's plan to put right th state of affairs rests on these components: **Salaries and careers.** Teaching posts will ordinarily be filled only by people with PhD degrees. Teaching salaries will be tied to those in the public service and a system has been instituted by means of which the salaries of academics with special responsibility and competence in research, teaching or administration may be augmented if those concerned are offered special contracts of employment by the education ministry. The ministry says it has received 15,000 applications for such contracts, the effect of which will be to increase the salary of a beginning academic from FF8,000 a month to FF13,000. Allègre (see page 133) reckon that the average uplift of salaries will be 25 per cent.

As part of the process of deliberately preparing people for careers as academics, the ministry has set up thirteen *centres d'initiation à l'enseignement supérieur* at which, it is expected, graduate students seeking careers at universities will attend for one week twice a year during the average three-year duration of a PhD course. Graduate students selected for these programmes will be paid extra (a total of FF9,200 a month), but will be expected to teach classes (usually in the *premier cycle*) and to hold small-group seminars while preparing their theses. The plan is to increase the 3,000 people at present following this programme to a total of 6,000 (implying an annual production of 2,000 academics in all fields); graduates of the *grandes écoles* will be extra. — **New universities**. Existing universities earn intangible credit at the Ministère National de l'Éducation by their willingness to fall in with the notion of expansion, but there are limits to what can be accomplished on existing sites. Montpellier (see page 138), with 50,000 students, is pondering whether it could take an extra 20,000; one solution would be to spin off first-year teaching to Nîmes, 60 km away. Nîmes, with ambitions to be a university-city in its own right, is not so sure.

So France, almost alone among industrialized countries, is embarked on creating eight new universities — four in Paris and four elsewhere. The new Parisian universities, which will be multidisciplinary, will be surburban universities — at Cergy-Pointoise, Versailles and Mame la Vallée et Evry with a dependent campus at Melun-Senart. But it is also planned to increase by rebuilding the capacity of the Sorbonne and other universities in central Paris.

The hope is that the four new provincial universities, the locations of which have not yet been chosen, are meant partly to meet the demand for higher education which is, even at present, unsatisfied in west and central France. (There is at present a net movement of students towards Paris, the southwest and the Lyon region.) The problem will be to persuade able academics to move away from the centre.

Research. The government acknowledges the need to "arrest the slow erosion of university research over the past several years". The ministry of education hopes to accomplish this by several means.

There will be a system of competitive grants for research and scholarship administered by a committee (the Conseil Scientifique de l'Education Nationale) under the Nobel prizewinning chemist Jean-Marie Lehn. Salary supplements for academic-researchers should work towards the same end.

It may also help that the government plans to encourage the emergence of new university centres of excellence. It has nominated a handful of places which, "by the quality of their research, the diversity of their teaching and the the attractiveness of their locations", may rival "Oxford, Heidelberg and Berkeley" in the united Europe of 1993. The ministry has so far nominated Grenoble, Strasbourg, Orsay-Polytechnique (southwest of Paris) and Toulouse; it promises further names — but a few of them — before 1993.

Organization. The ministry of education, at the Napoleonic hub of France, is used to redefining and rebalancing the interests of the centre and periphery. The new calculation is that four-year renegotiable contracts with the ministry of education will give universities an incentive to skimp on spending in fields in which costs are elastic, and to invest the funds they save where there are intellectual opportunities, or students to be recruited. The council of ministers, on the recommendation of the ministry, will continue to appoint the rectors of the universities.

Several innovations are promised. A study is under way (with the ministry of economics and finance) to see whether budgetary procedures can be radically simplified and whether real-time ("*en temps réel*") techniques of data processing can assist the administration of universities. (Ways of counting students would be a big help.)

Cosmetics. The ministry, which hopes that it will be possible to double the number of doctoral students preparing theses in the five years ahead, plans to set up an organization for monitoring all theses under preparation. It is hoped that this information (to be published annually) will form the basis for determining university research policy as well as for comparisons between French and other research. ☐

Lyon's hot-house university

WHY should French teenagers compete so fiercely to go to universities that are unable, by their constitution, to award degrees? Because the universities are not universities at all, but *grandes écoles*.

These citadels of French higher education owe their existence to functional considerations: how best can the state secure the services of able people who have been specially trained in certain fields? By recruiting them young and competitively, by making them civil servants for at least ten years and then, by training them. Thus was the *École Polytechnique* Napoleon's device for assuring a supply of artillery officers.

By definition, the *grandes écoles* are in Paris, or at least they were. But in the 1980s the ministry of education embarked on an experiment to see whether they could be transplanted to provincial soil. Now, after more than a decade of heart-searching and hard work, a version of the *Ecole Normale Supérieure* has been transplanted from Saint Cloud, in Paris, to a complex of post-Modern buildings on the site of an old abattoir in this provincial city, now the next largest after Marseille.

The Ecole Normale Supérieure de Lyon has taken in 100 students in each of the past two years. They are a cut from those successful in the national *concours*. Most give themselves an extra two years preparation after *le bac* before entering the competition, which means that *normaliens* are usually 20 years old when they begin their studies. Although most of those entering the annual competition give one of the Parisian schools as their first choice, they (and their teachers) know they come from the top 0.1 per cent of whatever proxy for the national IQ distribution is measured by the *concours*.

Moving the school from Saint Cloud to Lyon has not been trouble-free. The idea seems first to have been mooted in the mid-1970s, and more or less agreed by the arrival of the Socialist government in 1981. At that stage, those threatened with banishment from Paris, and their unions, pleaded with the new government to put a stop to the plan. But the then minister of education, having brooded for some time, decided not merely that the move should go ahead, but that Lyon's floor-area should be increased by 11,000 m^2 to a total of 36,000 m^2.

Guy Aubert, appointed director of the new school two years ago, is an energetic man; among other things, he reckons to travel 50,000 km a year on the autoroute between his laboratory at Grenoble and the school at Lyon. He has high ambitions, not least that of making Lyon the best of this esoteric bunch, as follows:

- **To get the best students**. Even at the top, competition remains fierce. Lyon has to stake its claim on the affections of the brightest few hundred making their way to the *grandes écoles* by the reputation it establishes in the next few years. The counter-attractions of Paris will persist. But even as things are, 3,000 people compete for the 100 places at Lyon. Competence in some foreign language is required. French entrants are paid as junior civil servants.
- **Education through research**. Lyon offers three options — mathematics and *informatique*, science of matter (physics or chemistry) and life and Earth science. From the outset, students at Lyon will be plunged into research (and, during the first two years, taught to write and speak English). The requirements vary from one department to another, but most students spend half of the first three years of the four-year course on laboratory work and research. In the process of doing so, they normally acquire (from the University of Lyon) a first degree and, usually, the *diplôme d'études approfondies* (a necessary but not sufficient qualification for teaching at a university). Students at Lyon follow as a matter of course the laboratory-based *magistère* curriculum. They spend the last of their four years either preparing for a two- or three-year PhD course or in qualifying as fully fledged teachers in higher education (the process known as *Agrégation*. Aubert expects that 9 out of 10 will head towards a PhD.
- **Internationalization**. Like everybody else in France, Aubert is scheming to do his bit for the integration of Europe. One possibility is to recruit students from elsewhere to Lyon, perhaps as many as 50 each year. (The statutes allow foreign students to attend, and to pay no tuition fees, but they would not be paid or other-

Polytechnic Institutes

THREE relatively new institutions, in many ways intermediate in character between the *grandes écoles* and the national universities, have a particular influence. The best known is the Institut National Polytechnique de Grenoble, with roughly 3,000 students and an associated group of *grandes écoles* specializing in technical fields. There is also an Institut National Polytechnique at Toulouse and another in Lorraine.

All three were founded in the early 1970s as a means of stiffening higher technical education and lending coherence to its academic procedures. All are relatively small in terms of student numbers — between them the institutes have about 8,000 students. ☐

alt with as if they were French civil ts.) News of this scheme advertised yon's research network apparently ught 18 university people from else- ere in the European Communities and e European Free Trade Area to an nthusiastic meeting on 7 June. Further developments are awaited.

■ **Liberalization**. To guard against the danger that the *normaliens* will be over-narrowly educated, there is a scheme to mix students from the University of Lyon in with them. But there are no plans to follow, for example, the Massauchussetts Institute of Technology in introducing liberal studies of some kind to the curriculum.

■ **Research**. In the long run, the success of the Ecole Normale Supérieure de Lyon will hang on the reputation it acquires in research. There are almost 150 researchers already at work, two-thirds of them on the payrolls of either CNRS or INSERM. It is a guiding principle that there should be strong links between the school and the national research organization, with the result that two of the university's six laboratories are joint CNRS-Lyon institutes while the others are less formally linked to CNRS. Aubert is entirely content to think of using laboratories at Grenoble as well as Lyon both as research partners for Lyon's academics and as places at which the *école*'s students can follow their *magistère* programmes.

Much thought seems to have gone into the formulation of research programmes which, while having roots in traditional research, are conceptually innovative. For example, the people in *informatique* are concerned with the logic of parallel computers, the physics department with instabilities and order–disorder transitions in liquids.

So has the move indeed confirmed that it is possible to live, and to remain intellectually alive, outside Paris? Almost all the academics at Lyon have moved from Paris, although not from the old campus at Saint Cloud. Interestingly, three people (for this purpose a random sample in that their qualifications were that they speak English) had all used the opportunity of the move to Lyon to change the emphasis of their research. One common goal seems to be the creation of a distinctive line of enquiry, capable of catching national and international attention.

Those who have made the move are youngish people (and Aubert is proud of the average age of the faculty at Lyon). The reason is straightforward: as one explained, "the older people would not move". But even some of those who have done so acknowledge that there are ways in which "Paris is better". What they mean is that the extramural aspects of life in Lyon are not as varied as in the capital. That is perhaps something else on which Aubert should be working. ☐

UNIVERSITY OF PARIS

What's in a number?

Tell the average academic in Chicago, Manchester, Tokyo (and probably anywhere else outside France) that you teach at the University of Paris and he is likely to say "Ah!, the Sorbonne", perhaps adding that it is "the oldest university in the world, isn't it?". In fact, the Sorbonne ceased to exist in 1790 and was given to the University of Paris in 1808.

In troubled 1968, that was divided into 13 campuses or, more precisely, what is now the Académie de Paris comprises 13 universities — each one numbered. But the numbers have verbal equivalents. A researcher in physics might, for example, give his address as "Paris XI", but say he works at "Orsay". And the rector would call himself "*Professeur en Sorbonne*", not at Université de Paris I.

The confusion is even greater than it first appears. While three campuses might still call themselves "the Sorbonne", being on the original campus in the Latin Quarter, Paris I is known as "Tolbiac", Paris III as "Censier" and only Paris IV, the old faculty of letters and arts, still calls itself "Sorbonne". Meanwhile, the Université Pierre et Marie Curie is always known as Paris VI, while Paris VIII, set up as an experimental university after May 1968, is called "Vincennes", after its original location in the eastern suburbs, but is now at St Denis in the north.

Foreign academics would, however, be right in thinking that the University of Paris is, with Bologna, older than other European universities. It began as a theological school attached to the cathedral of Notre Dame. As the number of tutors grew, so did the variety of disciplines. Th whole became known as the university while tutors within a discipline groupe together as faculties.

The Sorbonne appeared in 1253, as theological school founded by Robert de Sorbon, and had a stormy history. It was opposed to the establishment of Jesuit orders in France and sided with the English against Joan of Arc. The Sorbonne was closed by Convention in 1790.

PARIS UNIVERSITY BY NUMBERS

Paris I	Pantheon-Sorbonne	"Tolbiac"
Paris II	(economic law, social sciences)	"Assas"
Paris III	Sorbonne Nouvelle	"Censier"
Paris IV	Sorbonne	—
Paris V	Rene Descartes	—
Paris VI	Pierre et Marie Curie	—
Paris VII	—	"Jussieu"
Paris VIII	Vincennes at Saint-Denis	—
Paris IX	Dauphine	—
Paris X	Nanterre	—
Paris XI	Paris-Sud	"Orsay"
Paris XII	Paris Val de Marne	"Creteil"
Paris XIII	—	"Villetaneuse"

Once integrated into the University of Paris, the "Sorbonne" refused to accept the teaching of new disciplines. Consequently, new universities were founded to teach sciences, humanities and the social sciences. Only after 1968 did universities throughout France become truly multidisciplinary. Today, in the first major reforms since the 1970s, eight new universities are planned, four in the Paris area.

With the growth of the university system as a whole, the numbers game has spread. In Montpellier, for example, there are "Montpellier I", "II" and "III", the first (teaching arts, literature and the humanities) also known as "Université de Paul Valéry".

Peter Coles

MAGISTERES

Gaining distinction by degrees

If universities can do little to select the students they teach, they can at seek to distinguish between those who leave with degrees. That is one function of the *magistère* programme, originally conceived by Jean-Pierre Chevènement in the early 1980s as a way of redressing the balance between the *grandes écoles* and the regular universities.

The result is a highly selective beefed-up diploma for university students called the *magistère*. First introduced in 1985 in 70 selected university departments, in a wide range of disciplines, the *magistère* is meant to prepare students for research or industrial careers no less promising than those of engineers from the *grandes écoles*.

Students enter the *magistère* after the first cycle (first two years) of university education, but must have a special mention in their diploma (DEUG). Because the *magistère* degree is not national, but awarded by the university, students almost always carry on their regular studies.

In the first year, students carry out supervised research at a state laboratory, one half day each week. In the second, they are working full-time in a research laboratory and, in France, are given priority for grants under the European Commission's Erasmus and Comett programmes to study abroad. Students from the Joseph Fourier University at Lyon last year went to the University of Sussex and others to Philips in Eindhoven, for example.

The ministry of education has no plans to expand the scheme at present; much will no doubt depend on an evaluation of the scheme completed by Dr Guy Aubert.

Peter Coles

GRENOBLE

Dissembling Alpine science city

If France were the Soviet Union, this Alpine city would be named Akademgorodok and everybody would be a little self-conscious about its strategic and economic importance. But the city's ambitions seem to lie somewhere between an upmarket ski resort and a smaller version of Paris (to which every provincial city aspires).

As if in that cause, the mayor of Grenoble, M. Carrignon, has in the past few weeks put the city on the national political map by advising members of the Republican (centrist) party to which he belongs to vote Socialist in the local elections so as to defeat the candidates of the extreme-right National Front. For his pains, Carrignon has been suspended from party membership.

But the nature of the place is apparent from the autoroute from Lyon, just over 100 km away. First, there are traditional conveyor belts carrying limestone from a scar on a miniature alp to the east to the cement factories in the valley of the Isère, then the unmistakable outline of a particle accelerator taking shape at about the point at which the exit signs read "*Polygone scientifique*". The circular hole is, of course, the European Synchrotron, the 6 GeV electron synchrotron designed to be a purpose-built source of X-rays and γ-rays when it is commissioned in 1993.

Grenoble has grown to be the place it is by a sequence of accidents, among which the first was its choice as the site for the basic research laboratory of the Commissariat à l'Energie Atomique (CEA). Another influence is more personal — that of Dr Louis Néel, who was still a member of the physics department at the University of Grenoble when he won a Nobel Prize (in 1970) for the discovery of antiferromagnetism. Néel laid the foundations for tempting to Grenoble the half a dozen CNRS laboratories, mostly centred on condensed-matter physics, that constitute the Polygone.

What more natural than that the city should also be the site of the thermal nuclear reactor which, under the name of Institut Laue-Langevin (ILL) is one of Europe's most prolific sources of thermal neutrons, used mostly for structural studies? The institute is jointly financed by France and West Germany, with smaller contributions from other members of the collaboration. Tucked away in the same *polygone* is a Max-Planck Institute of solid state physics, visible proof of West German commitment to the place.

Guessing at the numbers of scientific and technical people is more difficult at Grenoble than at, say, Novosibirsk, but CNRS is thought to employ about 700 qualified scientists here, CEA perhaps twice as many, while the less permanent populations of ILL and, eventually, of the European synchrotron laboratory, may account for a further 1,000. Then there is the university. Allowing for technicians and administrative people, direct employment in Grenoble's public laboratories is probably not far short of 15,000, a substantial proportion of the regional population, estimated at about 400,000.

But that, people are quick to say, overlooks the uncounted scientists and engineers working for the small technical enterprises that have sprung up (with the encouragement of the local authorities) at Grenoble, originally as suppliers of goods and services to the public laboratories, but which have now cultivated national and international ambitions. (The continuation of the autoroute from Lyon is plainly marked "Turin", but francophone Switzerland is even closer.)

Grenoble, in other words, is a living proof that life outside Paris is possible, and can even be rewarding. One benefit has been that the laboratory-based culture has been able to forge a strong relationship with the University of Grenoble, to their mutual benefit. CNRS laboratories regularly have academics among their staff members, while researchers teach courses at the university. (The incentive is not monetary, but the simple consideration that teaching experience counts as a plus when promotions are considered within CNRS.) Similarly, academics and people from the various laboratories sit on each others' assessment, promotion and strategic committees.

The academic links with research are plain to see. At the CNRS Laboratoire d'Etudes des Propriétes Electroniques des Solides, graduate students (from other universities as well as Grenoble) outnumber fully fledged researchers (a third of whom are Grenoble academics).

This fruitful symbiosis rests in part on bread-and-butter considerations: academics have access to more sophisticated equipment than university laboratories can usually provide, while laboratories can profit from the flexibility of the funds provided by the university towards the overhead costs of their academics' and their students' research costs.

But there is more to say than that. Dr Guy Aubert, head of the CNRS Service National des Champs Intenses until two years ago says that, in the physical sciences, CNRS offers the only mechanism in France by which the quality of the research people do can be sympathetically and objectively assessed. To link a university with the CNRS system provides it with a yardstick for the measurement of self-improvement and the means thereto.

It goes without saying that the symbiosis provides the laboratories with recruits who can hit the grounds running. Grenoble is both the originator and an enthusiastic exponent of the *magistère* programme (see opposite) by which students are introduced to research while still working for their first degrees, partly by being taught by researchers and partly by working in research laboratories or at computer consoles. The *polygone* has provided a sparkling new building in which to house the *magistère* students.

There is a general lesson to be learned from all this: CNRS laboratories can profoundly influence a nearby university. It is not just that CNRS laboratories can provide neighbouring academics with facilities for research that would otherwise be lacking (thereby making the universities attractive to potential teachers), but that they can also hope to mould both the university curriculum and the composition of its faculty.

But the symbiosis requires readiness on both sides. Other CNRS laboratories complain that they must take in graduate students from neighbouring universities over whose curriculum they have had virtually no influence. *Formation*, the academics say, "that's our responsibility". Then the symbiosis cannot work. Nor can it when there is no CNRS or INSERM laboratory within reasonable range.

It is no wonder that Grenoble (with Strasbourg, Orsay and Toulouse) has been singled out as one of the outstanding university centres in France. In reality, there are both the Polytechnic University, with 2,000 students, and the three campuses of the University of Grenoble dealing (by numbers) with science and technology (the Joseph Fourier University), with social sciences and with arts and literature. The city has a student population of 30,000.

Not everything in Grenoble is lovely. The worry about salaries, generally through CNRS, quickly bubbles to the surface. Working researchers say that industrial salaries are generally 50 per cent higher than their own. Most people acknowledge that it is worth paying something for the extra freedom and interest that their laboratories allow. But 50 per cent? Guy Aubert says that even laboratory chiefs are now regularly head-hunted — most expect to get one reasonable offer a year.

Promotion is also a constant worry. Becoming a *directeur de recherche* (a salary grade), requires not just a *concours*, but passing through the eye of a needle which appears ever to shrink in aperture.

Some at Grenoble are also alarmed at the shrinking proportion of CNRS's income available for the direct support of research. This relatively well-heeled group of laboratories is well placed to secure outside contracts, and does well, but is alarmed that external dependence may eventually threaten what it considers to be its core research. □

POLIS

uropean Los Angeles?

TPELLIER has all the makings of Los geles, but it has a long way to go. For time being, it differs by a fragment of a bstantial mediaeval city wall, the like of which has never been seen in California, while it is still possible to look at clear blue sky. But not for long, if the fastest-growing city in France can keep up the momentum, it may soon have enough road vehicles to generate a pall of smog.

Montpellier also has the distinction of beginning as a university town. There are 200,000 permanent residents, but 50,000 university students who come and go.

Apart from the abundant youthfulness, the city has gone in for three contrasting and inconsistent architectural gimmicks whose like cannot easily be seen elsewhere. First, the old centre of the city has been covered with a sheet of terrazzo as vast as St Peter's Square, from whose edges protrude the upper floors of modern buildings, most of them apparently triangular, which are founded on solid earth. (The centrepiece of the display is a theatre, the Comédie, in which few plays play.)

Second, there is a gigantic air-conditioned bunker a good 300 m long in a distant corner, said to have cost more than $2,000 million to build. It is a conference centre of the most modern kind, which provides the city with a car park and which is inhabited by the chamber of commerce and industry.

Third, there is the new home of the Conseil Général, the provincial government, constructed to a kind of athenian plan; there are half a dozen post-modern replicas of the portico of the Parthenon (with office suites behind) arranged in a semicircle and separated by a highway and an artificial river from the central office block, in glass and soft brown stone rising to a dozen stories. One Montpellier driver thinks the river a huge joke: "it would take a long time to get to the sea that way".

What is happening is that Montpellier believes it has a chance to become the most important city in the arc of the Mediterranean between Gibraltar and Marseilles. One picquant feature of the development is that the Socialist mayor of the city, Georges Frèche, and the Republican administration of the region, have sunk their political differences in this common cause.

Professor Roger Brunet, a geographer who is the director of the CNRS-financed "public interest group" RECLUS based at Montpellier, explains that there is a "launch-window" within which the city must somehow make its mark. ("RECLUS" stands for Réseau d'Etude des Changements dans lesLocalisations et des Unités Spatiales.)

The window opened in 1988, when the national government devolved to the departments certain responsibilities for education, planning and industrial development, and when Spain and Portugal joined the European Communities, enlarging the city's vision to the West. But growth had begun before that, in 1965, when IBM chose Montpellier for a manufacturing plant (now the chief source of employment after the three universities). Legend has it that somebody at IBM drew a line from the company's research laboratory at Nice to its import base at Bordeaux, and found Montpellier roughly half-way between.

With that beginning, Montpellier's ambition is to become a technopolis — one blessed with sun and sea (5 km to the south, past the airport and through a group of small factories). There are also the Cevennes mountains 10 km to the north. The other assets are the universities and the large group of research council laboratories (INRA is especially well established) scattered about the city. The city is also the main base of CIRAD, with responsibility for the cooperative development of tropical agriculture. The city and the region are setting out deliberately to exploit these assets, seeking to attract small and large enterprises in agriculture, pharmaceuticals and *informatique* to science parks physically designed to be contiguous with the laboratories in related fields.

Brunet, whose unit has general interests (it is using its expertise in cartography to compile an atlas of the world as well as of France, and has advanced the doctrine of territoriality as central to the present development of Europe) is a bystander, but an interested one. One of his projects is the conceptual design of a highway from Gibraltar to Constantinople, on which Montpellier would be a crucial staging-post.

So when will the launch-window close? Montpellier seems realistically to appreciate that the world has become competitive. Toulouse, the centre of the aerospace and much of the electronics industry, is just 100 km to the northwest. More irritating, Nîmes, 50 km in the other direction, and best known for its splendid Roman ampitheatre, is nursing ambitions to expand (as, indeed, it is). The window will close only if the plans now hatched fail to materialize. Nobody in Montpellier believes that will happen. ☐

NUMERACY

Industrial mathematics booms

INDUSTRY seems to have taken to the heavy-duty computer and the techniques of model-building with the enthusiasm with which the French public has embraced Minitel — the ubiquitous domestic videotext service originally devised as an electronic telephone directory, but now used for gathering general information, train times for example. The result is that industrial researchers have set out deliberately to recruit mathematicians to their cause.

The impetus is twofold. Simulation is often much cheaper and quicker than experimental investigation, vividly apparent in the use of simulation by aeroengine manufacturers in the design of turbine blades (whence, in part, the present concentration of interest in fluid dynamics). The recognition of that truth is not unique to France. But what may be is the recognition by French industry that mathematics is one of the country's strongest suits, and that mathematicians are not always as unwilling to bother with practical problems as their reputation suggests.

But how to capture that resource? Elf's Solaize laboratory believes it has found an effective way of doing this, on behalf of the company's research effort as a whole. J-P. Valentin is a regular mathematician on the laboratory's full-time payroll who is not merely allowed, but required, to spend half his time on academic work.

For the rest, Valentin's job is a mix of persuading researchers in the company's laboratories that many of their problems are often essentially mathematical problems and then of recruiting appropriate outside consultants who can help to solve them. He says that he would be unable to perform the second role if he were not himself a practising mathematician, able to mix with others on equal terms at conferences.

He describes the first function as if it were a kind of psychoanalysis. Most researchers, unaware of recent advances in mathematics, are slow and even unwilling to acknowledge that their problems may be mathematical in character. People used to making measurements with an experimental rig prefer to stick with what they know. He also claims to be a kind of midwife, recognizing that one research group may already have a solution to another's problem.

Valentin cites as an important technique in his business the organization of regular meetings at which Elf-sponsored PhD students (there are 120 of them scattered about the universities) present accounts of their research in the presence of their academic supervisors. These serve, he says, not just as ways of recruiting consultants, but as a powerful means of deepen the company's corporate culture of mathematics. ☐

NUCLEAR ENERGY

Reactors hit financial trouble

FRANCE's ambitious nuclear programme has wound up in a curious dispute over the ownership of the chief reactor-builder, Framatome, in whose shares its chief rival, the Compagnie Générale d'Electricité (CGE) has acquired a controlling stake. The government is in a quandary over whether to renationalize Framatome.

This is an unexpected but unavoidable outcome of the past two decades, during which France has striven to make its nuclear energy industry second only to that of the United States. But now, with a slump in oil prices and a worldwide wariness after the Chernobyl accident, it has found itself with knowhow nobody wants and more electricity than it needs.

The 53 reactors belonging to the nationalized EDF (Electricité de France) — mostly of the pressurized water type, but including one fast-breeder reactor — supply 75 per cent of the country's 342,000 million kilowatt-hours of electricity production. With very few coal, gas and oil resources, France began strengthening its nuclear capability during the 1970s oil crisis. Successive governments continued the expansion policy, supported by a generally enthusiastic public.

France also has stakes in all aspects of the generation cycle. Cogéma, the industrial subsidiary of the Commissariat à l'Energie Atomique (CEA), the state research agency, has almost cornered the world market in irradiated fuel reprocessing at its La Hague plant on the coast of Normandy, on the English Channel, with a capacity intended to be 1,600 tonnes a year by 1992 and as much as 40,000 tonnes by 2000.

Just as France's own construction programme matured, the Chernobyl accident led other countries to freeze their construction programmes, leaving France's two major manufacturers of nuclear technology, Framatome and CGE, with little hope of critical export orders. The situation was made worse by a saturated home market. In the 1980s, ten new reactors were commissioned to meet an expected demand that never materialized. And a new generation of fast-breeder reactors was planned to follow the experimental 1,200 MW Superphénix plant at Creys-Malville on the Swiss border. But soaring costs, unreliability, cheap uranium and national overproduction led this programme to be shelved.

To add to the slump in enthusiasm for nuclear reactor construction, doubts have now been raised about the safety of existing reactors. Earlier this year, it was revealed that the wrong bolts had been used in maintenance on safety valves at the Gravelines site on the English Channel coast near the Belgian border. A report commissioned by EDF revealed similar incidents elsewhere and that the risk of a major accident in the next 20 years at one of the French reactors could be much higher than previous estimates. There are six 1,300 MW reactors on the Gravelines site; even the remote threat of an accident has made France's neighbours twitchy.

But the need to replace old reactors, combined with expectations that industrial growth will increase energy demand in the next decade, means that the reactor construction programme is not dead. Only last week, EDF promised that a new 1,400 MW reactor at Civaux would get the go-ahead next year after long delays.

The prospect of renewed growth has put Framatome and CGE at the heart of a political storm. Last month, CGE bought out shares in Framatome held by Dumez, giving it a 52 per cent of the company, a controlling stake. The government feels uncomfortable with its 45 per cent minority share (35 per cent CEA and 10 per cent EDF) and is now wondering whether to intervene by nationalizing Framatome again, so as to gain control over little-valued but potentially critical expertise.

CGE, privatized in 1987, is against such a move and, in any case, nationalization is likely to run up against a ruling of the present government guaranteeing neither privatizations nor nationalizations of industries in the current mandate.

Peter Coles

Science parks multiply

RESEARCH may not immediately make nations prosperous, but it can do wonders for the prosperity of cities. That seems to be the principle on which several municipal governments are now working, from Lille and Rennes in the north and Lyon in the centre to Montpellier in the southwest.

So science parks are multiplying. At Montpellier, there are no fewer than three, conceptually centred on the city's intellectual assets.

The presence of IBM has stimulated the city, in the 1980s, to persuade small companies in *informatique*, robotics and artificial intelligence to what it calls its Parc du Millénaire.

Agropolis is the name for the similar effort in agronomy and agricultural biotechnology, the core of which is the complex of government laboratories with interests in food and agriculture, between them employing an estimated 1,800 people.

There is also what Montpellier calls its Euromedicine park, to which the city has attracted more than 20 businesses and research laboratories in the fields of pharmaceuticals and medical instrumentation.

What stands out from these endeavours is that the public laboratories are more than merely compliant, they are encouraging. It is public policy not only that France should increasingly rely on technology for its prosperity, but that neighbours with interests in research may be a source of research contracts, perhaps even of better jobs. ☐

INDUSTRIAL RESEARCH

Getting back to business

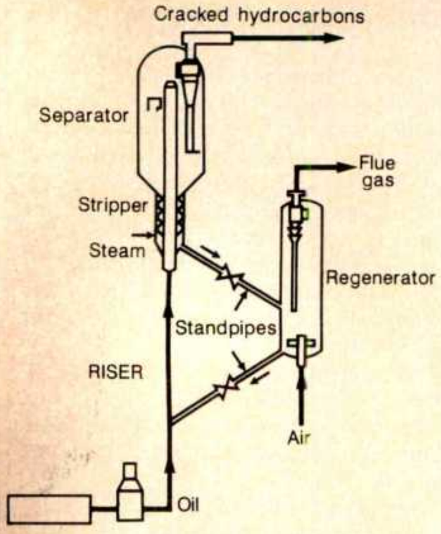
CRUDE oil refiners in France have been driven into a corner — and into research — by the nuclear energy industry, and by the collapse in the market for heating oil. Elf-Aquitaine, which operates three refineries in France, says that the annual throughput of crude has fallen from 100 million tonnes a year to only 80 million tonnes, and demand for heating oil has fallen even more drastically.

The problem is how to win a greater yield of saleable products, notably petrol (gasoline, otherwise *essence*) by the intelligent cracking of crude. The company claims to be a pioneer in the automatic control of refinery operations. Now, at its research laboratory at Solaize, south of Lyon, it has a team of eight people perfecting the operating parameters of catalytic petroleum crackers, believing that understanding will lead to a greater yield of lighter fractions.

The research programme has been a joint effort by Elf and CNRS since 1956. A group of four CNRS researchers have been seconded to the Elf laboratory. When their project finishes two years from now, the CNRS people will return to their laboratories not merely with a better appreciation of industrial problems, but with an expertise in the operation of large pilot plants. Nobody seems alarmed that they will also be the better able to advise Elf's competitors.

The problem of optimizing the design and operating parameters of a cat cracker is complex. J.R. Bernard, the Elf researcher who leads the group, likens it to the problems that arise in the design of nuclear fuel rods and the fixing of operating parameters.

The catalysts are zeolites, used in the form of 60-μm grains which give the material the appearance of a brownish-pink powder. Standard practice entails the use of heavier distillation fraction of the crude to support an upward-moving fluidized bed of catalyst in what is inevitably called a 'riser'. The cracking process appears to require as little as 2 seconds, which is a pointer to the speed at which materials are circulated through the plant. Petroleum products are stripped from the catalyst by steam and the catalyst recycled



Catalytic cracking plant Elf style.

through an air-driven regenerator whose chief function is to remove solid carbon, or 'coke', from the catalyst (see figure).

In the drive for increased gasoline output, schemes for the hydrogenation of heavier crude fractions are being canvassed, further complicating the optimization of cracking plants.

At Solaize, the joint Elf-CNRS team has been forced back to basics, fitting a pilot-plant housed in a hangar-like building with instruments and using radioactive tracers for tracking the movement of zeolite through its cycle. The objective is to refine a mathematical model of a cracking plant which is being elaborated, with the objective of fixing the parameters of more efficient cracking plants linked with hydrogenation units. The same model will eventually be the basis of programs for the automated control of refinery operations.

Bernard enthuses about the niceties of the operation of standard cracking plants which the study has brought to light. Even questions such as the effect of the riser walls on the movement of zeolite had previously gone unanswered, he says. That there should be friction had been expected, but the velocity profiles across the riser that have now been measured, and the patchiness of zeolite concentration across the riser, were not expected.

Nobody at Solaize is able to say what the economic benefits of the programme will be. Rather, the assumption seems to be that a business which depends on the successful operation of machines such as cat crackers had better understand them in as much detail as it can.

Elf is not alone among French companies in having taken a deliberate decision in the past decade to spend more of its effort on basic research. Claude Jablon, corporate director of research, says that the company (which differs from more conventional oil companies in its strong interest in chemicals and pharmaceuticals) employs 4,500 people in research laboratories scattered through France, elsewhere in Western Europe and in North America. Of this effort, engaging some 4 per cent of the company's total staff, he reckons that 10 per cent is devoted to projects that will yield benefits only in the long term.

Just where the project to develop better asphalt fits in this is not clear. The company appears to have something of a success with a material called 'Styrelf', selling 300,000 tonnes a year of it. The idea is that hydrocarbon molecules of regular asphalt (non-volatile refinery fractions) have been covalently linked with styrene to form a kind of three-dimensional molecular network in which road metal (graded granite fragments) for highway surfaces can be embedded. Energy is being spent on the materials testing of various compositions of road surfaces, but, in the absence of a full understanding of why highway surfaces wear out or become distorted, faith is required to assure highway authorities that polymeric asphalt will last longer. ☐

SPACE

Is there profit as well as pride?

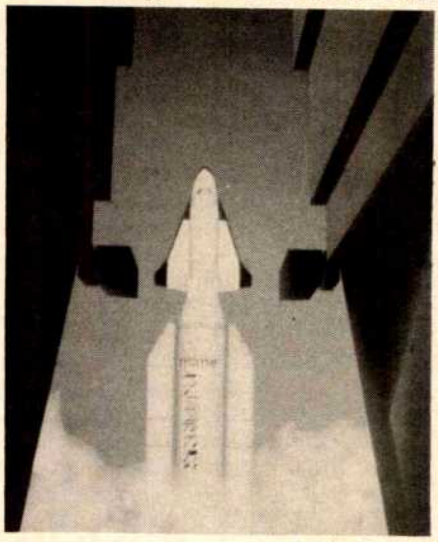
Over the past 25 years, France has emerged as the European leader in space technology, continuing to push forward and take expensive risks while its neighbours got cold feet. This fits with the high profile given to technology.

The academic elite graduating from the *grandes écoles* are called 'engineers', and electronic gadgetry sprouts regularly in Paris, from video in the metro stations to cable television. The Minitel telephone-linked interactive videotext system is the most successful in the world and France's high-speed trains (TGV) and modern metro systems are often cited as models elsewhere. High technology is seen as the key to economic survival in the next century.

France has had its own space programme since 1962, when the Centre National d'Etudes Spatiales, the national space agency, was founded. In 1975 it abandoned its own domestic rocket programme to cofound the 13-member European Space Agency (ESA).

Now, France contributes almost a third of ESA's $1,700 million budget, ahead of Germany and Italy and four times as much as Britain. It is no accident that ESA headquarters are in Paris, that the European commercial launch consortium — Arianespace with 50 per cent of the world market — is based in France, or that the first European cosmonaut was a Frenchman.

Always an enthusiastic partner in ESA, France pulled out all the stops at the 1987 ministerial meeting in The Hague, at which the agency's long-term plan was approved. The Hermes space plane developed by CNES was chosen to service the Columbus platform, intended as Europe's contribution to the US Freedom space station, despite criticism from Britain that the technology was out of date and that the plane was too small.



ESA

Ariane 5 will launch Hermes — both products of French initiatives.

But the price of the acceptance of Hermes is that France has to foot 45 per cent of the bill, a cool FF597 million in 1990. Furthermore, Hermes depends on a new generation of heavy-lift launcher, Ariane 5, to get into space and this, too, is 45 per cent French, with costs to France running at FF1,812 million this year.

But while Britain decided that the Hermes and Ariane 5 package was simply too expensive and dropped out, France found it had money to spare to boost its domestic space programme. In the 1990 civil research budget, CNES received FF7,187 million — almost 16 per cent of the entire budget and 11 per cent more than 1989.

Of this, FF352 million will go towards a fourth generation of the SPOT commercial remote-sensing satellite owned by CNES, which will have cost an estimated FF2,500 million by the time it is launched in 1995. Although SPOT loses money, its freely available high-resolution photographs have proved a thorn in the side of superpower defence departments and a way to vaunt France's prowess.

As European space technology has a distinctive French tinge, it is fitting that the new director of ESA should be a Frenchman, Jean-Marie Luton, who came from CNES. And with some tough negotiating ahead as the full costs of Hermes and Ariane 5 emerge, Luton will need all the backing he can get. **Peter Coles**

ORSTOM

INSTITUT FRANÇAIS DE RECHERCHE SCIENTIFIQUE POUR LE DEVELOPPEMENT EN COOPERATION

L'ORSTOM, Institut Français de Recherche Scientifique pour le Développement en Coopération, est un établissement public national à caractère scientifique et technologique, placé sous la double tutelle des Ministères de la Recherche et de la Coopération.
Il a pour mission de conduire des recherches de base finalisées, contribuant au développement des régions de la zone intertropicale en particulier par l'étude des milieux physiques, biologiques et humains de ces pays et par des recherches expérimentales visant à la maîtrise du développement.
Ces recherches sont conduites en coopération en fonction des choix scientifiques et technologiques définis en accord avec des partenaires français et étrangers. L'ORSTOM contribue également à la formation à la recherche et par la recherche de spécialistes français et étrangers.

Diffusion-Librairie
72, route d'Aulnay, 93143 Bondy Cedex
Fax. 48.47.30.88

ORSTOM, the French Scientific Research Institute for Development through Cooperation is a national public establishment of science and technology depending on both the Ministries of Research and Cooperation.
It is responsable for the conduct of finalized basic research, as a contribution towards the development of regions in the intertropical zone, through experimental research aimed at controlling the processes involved in development, and more precisely concerned with the study of the physical, biological and human environments in these countries.
This research is conducted through cooperation between French and foreign partners based on scientific and technological choices decided by mutual agreement. ORSTOM also provides assistance for training to or by research for French and foreign specialists.

NEW SCIENCE FROM MANCHESTER

Fractals in the physical sciences
HIDEKI TAKAYASU

This book is an introduction to fractals using over 30 examples from the fields of physics, biology, earth sciences and economics. Computer simulated fractals are also used and mathematical techniques are explained with concrete examples.

1990 176 pp. 0 7190 2485 4 Hb **£35.00/$70.00**

Soliton theory: a survey of results
Edited by ALLAN P. FORDY

Contains the basics of soliton theory but is primarily concerned to review the most important topics of current research interest under section headings: Solution methods; Physical applications; Hamiltonian theory; Algebraic and geometric structures; and Testing for complete integrability.

1990 449 pp. 0 7190 1491 3 Hb **£65.00/$130.00**

Oscillatory evolution processes
Quantitative analyses arising from applied science
I. GUMOWSKI

A guide to the use of evolution equations in modelling the behaviour of real systems (including analyses of experimental results) which will be of significant help to the many workers in empirical sciences.

1989 329 pp. 0 7190 2212 6 Hb **£55.00/$95.00**

Almost periodic operators and related nonlinear integrable systems
V. A. CHULAEVSKY

Deals with recent advances in the mathematical theory of non-ideal crystalline structures: the spectral theory of differential and finite-difference operators with almost periodic coefficients.

1989 105 pp. 0 7190 2667 9 Hb **£29.95/$65.00**

Human navigation and magnetoreception
R. ROBIN BAKER

Robin Baker's book is the most complete ever written on the subject of 'natural' navigation in humans. It presents detailed evidence and suggests how humans might perceive and use the Earth's magnetic field. Major points of contention are discussed and the result is a fascinating insight into the way new ideas are conceived, developed, tested and contested.

The arid–humid transition in the Sahara and the Sahel during the last deglaciation

Françoise Gasse*, Régis Téhet*, A. Durand†, Elisabeth Gibert* & Jean-Charles Fontes*

* Laboratoire d'Hydrologie et de Géochimie Isotopique, Bâtiment 504, Université Paris-Sud, 91405 Orsay Cedex, France
† Centre des Sciences de la Terre, Université de Bourgogne, 6, Boulevard Gabriel, 21000 Dijon, France

At the time of the Last Glacial Maximum, the Sahara and Sahel regions of North Africa were extremely dry. New records of rainfall show that, during the subsequent deglaciation, the transition from arid to humid conditions in these regions occurred synchronously in two main steps. Comparison with other records of palaeoclimate in Europe and the North Atlantic Ocean shows that certain common factors controlled changes in ocean and atmosphere dynamics during the deglaciation.

THE structure and timing of the last deglaciation is now well documented by numerous oceanic records and continental sequences between middle and high latitudes[1]. The last glacial-interglacial transition is not a simple linear response to astronomical forcing, and the two-step deglaciation model is now supported by detailed evidence[2-7]. Results of general circulation models suggest that climate change in the regions around the North Atlantic Ocean has been influenced greatly by changes in the northern Atlantic Ocean dynamics associated with the meltwater history of the Laurentide Ice Sheet. The effects of cold melt water may explain much of the nonlinear response of climate to astronomical forcing at high latitudes, but they do not provide a complete explanation for the sequence of change observed over North Africa[8].

In the Sahara and the Sahel, the Last Glacial Maximum (LGM) coincides with an episode of extreme aridity, whereas humid conditions prevailed during the early and mid-Holocene[9]. From simulated hydrological budgets, precipitation over the Sahel at 9 kyr BP (before present) was estimated at 125-130% in comparison with today[10]. The last deglaciation period thus corresponds to a major arid-to-humid transition (AHT).

Sediment cores of several tropical lakes span this transition[9]. In western sub-Saharan Africa (~5-15° N) and in the Tibesti mountains, the return of humid conditions before 12 kyr is well known from palaeolake and river-terrace studies[11-16], detailed palynological offshore profiles[17], and increases in the discharge of large rivers to the ocean[18]. A sudden drop in the level of several tropical lakes around 11-10 kyr has been tentatively linked to changes in the ocean circulation[19]. Large inputs of melt water from the Laurentide Ice Sheet in the northern North Atlantic would have reduced the North Atlantic Deep Water (NADW) formation during the Younger Dryas event[20], slowing down the North Atlantic's conveyor-belt circulation and inducing anomalies of sea surface temperature (SST)[19,21]. A colder North Atlantic may have stabilized the lower atmosphere and helped block the advection of moisture over North Africa[8] and may be responsible for a weaker monsoon rainfall over the northern tropics[19]. But few results ascertained from African lands provide a sufficiently defined chronology of the late Glacial to allow for high-resolution correlations with the oceans. Also, very little is known north of 15° N before 10-9 kyr. Because there are no continuous records from the early Holocene in the northern Sahara, the concept of a progressive reinstatement of a humid climate between the Equator and the Maghreb from 13 to 6 kyr has been advanced[22,23]. This hypothesis was followed by several authors[24,25], and developed in terms of general atmospheric circulation[23,26]. We show here that the re-establishment of wet conditions occurred before 12 kyr over both the northern and the southern margins of the Sahara, and that the climate evolution of the Sahel has been more complex than previously thought.

Although local hydrological factors may largely influence their water level and water chemistry[27,28], groundwater-fed palaeolakes of the Sahara and the Sahel can be very sensitive climate indicators provided that: (1) the extent of the recharge zone of the aquifer is relatively restricted to allow climate reconstruction at a local scale; (2) the response time to rainfall events is negligible; (3) the chemical and, in favourable cases, isotope characteristics of the ground water are known; (4) variations in hydrological conditions are not masked by evaporite dissolution; and (5) the hydrology is not influenced by sea level fluctuations. These conditions are met in two closed depressions selected from numerous sites studied in the PALHYDAF project[14,29], in the northern Sahara (Site 1, Sebkha Mellala, Algeria) and in the Sahel (Site 2, playa of Bougdouma, Niger), respectively (Fig. 1). Cores from the centre of these depressions provide continuous profiles from the late Glacial to the Holocene through sediments of aquatic origin (Fig. 1).

Crucial problems raised in ^{14}C dating in such environments, especially ageing by groundwater supplies and recrystallization due to water-table fluctuations, have been thoroughly discussed[15,29,30]. For carbonate dating, authigeny and the absence of recrystallization were verified by scanning electron microscopy (SEM) and the authigenic fraction (generally $<80\ \mu m$) was separated by sieving. The ^{14}C dates (conventional and accelerator mass spectrometry (AMS), uncorrected for secular variations) are regarded as valid when the ^{13}C content indicates that the total dissolved inorganic carbon (TDIC) of the water body was in (or close to) equilibrium with the atmospheric CO_2. In a given section, interpolated and extrapolated ages were calculated in intervals of similar lithofacies.

Three types of palaeohydrological indicators are considered: lithofacies and mineralogy, stable isotopes on carbonates, and biological remains. The stable isotope (^{13}C, ^{18}O) contents on authigenic inorganic carbonates are normalized with respect to calcite using the proportions, determined by X-ray diffractometry (XRD), of aragonite and dolomite and applying the proper isotope fractionation factors[31]. Carbonates from temperate lakes with very high turnover rates may reveal variations in the heavy isotope content of rains that are temperature-dependent[32-35]. In seasonally dry climates, the enrichment of the groundwater supply in heavy isotopes by evaporation is the major factor controlling the ^{18}O content[36]. In both cases, the crystallization temperature is not an important factor because the temperature dependence $\Delta\delta^{18}O_{carb}/\Delta T$ is much smaller than the variation in $\Delta\delta^{18}O_{carb}/\Delta\delta^{18}O_{water}$. In most North African lakes, the ^{18}O content of carbonates must be regarded as an indicator of the ratio of groundwater input to evaporation. The ^{13}C content gives further information on environmental conditions[15,28,30] such as water mixing, residence time and the intensity of biogenic production. Among the biological remains, attention is given to diatoms found in the Sahel sediments which allow chemical variables to be inferred from stratigraphic profiles by using calibration functions established from 200 modern African samples (refs 37, 38 and F.G., unpublished data).

Northern Sahara records: Sebkha Mellala, Algeria

Site 1 (32°11′ N, 5°12′ E, ~128 m.a.s.l. (metres above sea level); Fig. 1) is a closed depression, wind deflated through Cretaceous and Tertiary limestones and sandstones. It is hyperarid, with rare precipitation of northern origin (mean rainfall 42 mm yr^{-1}; mean evaporation 2,000 mm yr^{-1})[39]. The basin, dry today, is a discharge zone of the large confined aquifer of the 'Continental Intercalaire' which has its source mainly in the M'zab heights ~150 km to the west, but also in the Saharan Atlas mountains (Fig. 1)[40,41]. This deep (−1,000 m) aquifer supplies the local unconfined aquifer (water table at ~−6 m) through upward leakage of fossil water[40]. The basin has thus registered, with no lag, changes in precipitation in the recharge zones of the aquifer of the 'Continental Intercalaire'. The ground water, of $\mathrm{Na^+}$-$\mathrm{Mg^{2+}}$ or $\mathrm{Na^+}$-$\mathrm{Ca^{2+}}$ and $\mathrm{SO_4^{2-}}$-$\mathrm{Cl^-}$ type[41], is slightly saline (2.5-3.5‰). The stable isotope contents are −8.8‰ relative to standard mean ocean water (SMOW) for ^{18}O of the water and −11.5 to −9.1‰ relative to the PDB standard for ^{13}C of the TDIC. The ^{14}C content of the TDIC is below the detection limit[40,41]. The dimension of the aquifer suggests that these values apply to the Holocene.

The depression is filled by 8 m of sebkha and lake sediments (Fig. 1) that lie on the bedrock. Detailed results on the sedimentology, mineralogy, stable isotopes on inorganic and biogenic carbonates, element geochemistry of ostracod valves, and palaeobiology are discussed elsewhere[42,43]. The mineralogy and stable isotope variations are shown in Fig. 2. Radiocarbon ages on carbonates are accompanied by ^{13}C values > −4‰, far above that of the TDIC of the aquifer. Changes in ^{18}O content (−7.29 to +4.83‰) indicate large fluctuations in the ratio of groundwater influx to evaporation.

An arid climate is first registered (~15 kyr BP) by the dominance of aeolian sand, in association with gypsum which indicates a discrete and probably continuous discharge of $\mathrm{SO_4^{2-}}$-rich ground water. The overlying sediments are mainly composed of chemically precipitated minerals. The absence of detrital material indicates that the supply of local runoff is negligible, and suggests that the dunes of the Great Eastern Erg (Fig. 1) were colonized by vegetation. From 14.5 to 11 kyr, gypsum precipitation predominated in a saline water body, although minor amounts of authigenic carbonates allow AMS dating and stable isotope analyses. The filling of the depression at ~14.5 kyr, is recorded by a drastic drop in δ^{18}O (+0.31 to −7.21‰) and by high values of the ratio of groundwater input to evaporation at 12.8-12.7 and at ~12 kyr. The interval 10.6-9.3 kyr contains mostly gypsum and dolomite. SEM observations show that dolomite crystals are idiomorphic, and thus authigenic. The primary or early diagenetic dolomite represents the thermodynamically stable carbonate species in the Sebkha Mellala deposits after calcium removal through gypsum precipitation has increased the Mg/Ca initial ratio of 0.7 (ref. 41) in the highly concentrated residual solutions[44]. This disordered ($\mathrm{Mg_{44}}$, $\mathrm{Ca_{56}}$) dolomite is thus considered to be a post-gypsum evaporite. The interval 10.6-10.3 kyr has the highest δ^{18}O values (+1.72 to +4.83‰) in the whole section, and is considered to be the period of maximum local aridity. Arid conditions ended suddenly after

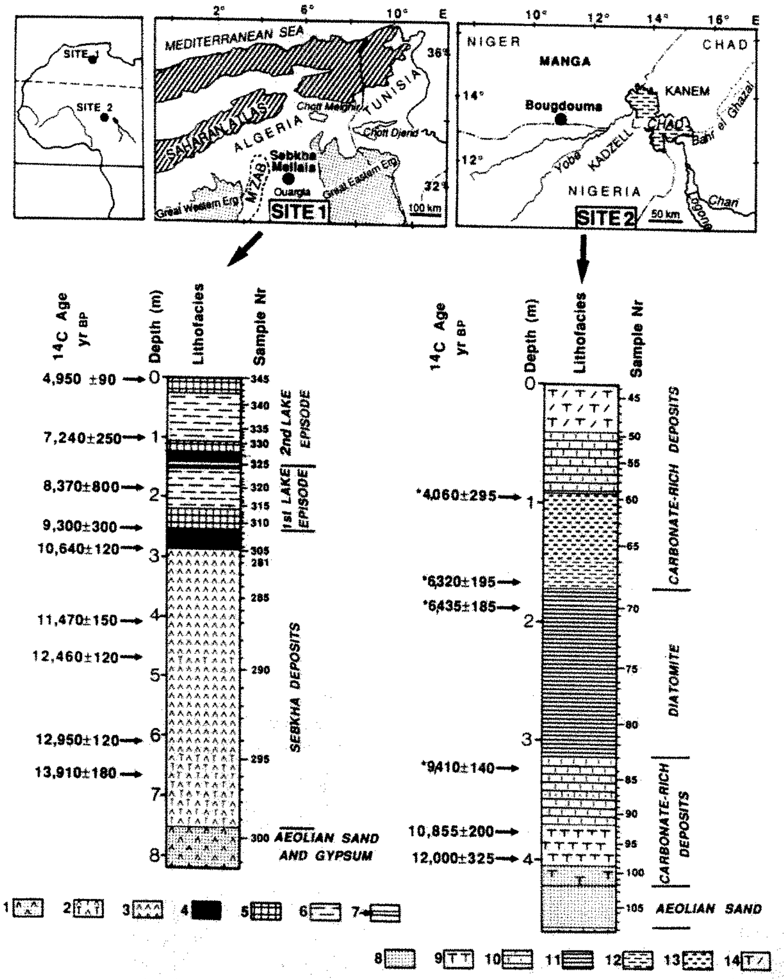

FIG. 1 Location map of the sites and simplified stratigraphy of the cores. Asterisks indicate radiocarbon ages of organic matter, others are ages of authigenic inorganic carbonate. Lithofacies: 1, aeolian sand and gypsum: 2, massive carbonate-rich gypsum deposit; 3, massive carbonate-poor gypsum deposit: 4, laminated gypsum and carbonates: 5, laminated carbonates free of mollusc shells: 6, alternation of shell beds and of carbonate and gypsum layers: 7, palaeosoil: 8, aeolian sand: 9, sandy carbonates: 10, diatomaceous carbonates: 11, diatomite-free carbonate: 12, calcareous clay: 13, calcareous sand: 14, carbonates and evaporites.

~9.3 kyr allowing the establishment of a lake, which was maintained until ~7.5 kyr. The humid episode (9.3-7.5 kyr) is registered by an abrupt decrease in $\delta^{18}O$ (+4.51 to −4.76‰), abrupt mineralogical changes and by the appearance of biological remains. Gypsum is still present, but the dilution of the solutions is indicated by the precipitation of Mg-calcite (associated with aragonite) and of calcite, which successively predominate in the sediments. The biological community reflects a saline shallow, but permanent, water body. No diatoms were found, possibly in response to secondary dissolution. The co-occurrence of freshwater organisms (such as the gastropod *Hydrobia* sp.) and of species able to tolerate marine-like conditions (such as the bivalve *Cerastoderma glaucum*, the foraminifera *Ammonia becarii, Triloculina* sp.) or hypersaline conditions (such as the gastropod *Potamides conicus*, the ostracod *Cyprideis* gr. *torosa*, or the charophyte *Lamprothamnium* cf. *papulosum*) indicates large short-term fluctuations in salinity, a common character of Holocene lakes of the northern Sahara[27,28]. The lake dried up at ~7.5 kyr, as recorded by a palaeosoil bracketed by dolomite-rich deposits, before the commencement of a new cycle of carbonate sedimentation dated from ~7.2 to 4.9 kyr. The top of the sequence is wind deflated.

We therefore identify two major steps in the transition from arid to humid conditions at ~14.5-12 (AHT1a) and 9.3-8.4 (AHT1b) kyr, the first one corresponding to several dry-wet oscillations. A third, smaller, step occurred at 7.5-7.2 kyr (AHT1c).

The Sahel records: Bougdouma, Niger

Site 2 (13°19′ N, 11°40′ E, 337 m.a.s.l; Fig. 1) lies in the Sahelian zone where most of the precipitation is due to summer squalls (75%) and monsoon rainfall[45] (mean rainfall ~250 mm yr; mean evaporation 2,000 mm yr^{-1} (ref. 46). The Manga plateau (Fig. 1) is the eroded surface of an old erg, probably of early Pleistocene age, and lies between ~400 (northwest) and 300 (southeast) m.a.s.l. over 120 km. The low gradient and the high vertical permeability of the aeolian sand do not allow for the development of a surface-drainage network. The unconfined aquifer is exclusively recharged by local rainfall[47], and crops out in numerous closed interdunal depressions. This was also the case during the late Quaternary, contrary to previous opinion[48] and the results of a related climate simulation[49], according to which the plateau was submerged by Lake Chad (present altitude 282 m.a.s.l.)[15,50]. Presently, the deepest depressions are occupied by small water bodies ranging from freshwater to hyperalkaline swamps, or playas with trona crusts (such as Site 2). In January 1989, ground water (Na^+-HCO_3^- type, conductivity = 5,800 μS cm^{-1}, pH 8.41, $\delta^{18}O = -4.01$‰ relative to SMOW, $\delta^{13}C \approx 0.0$‰ relative to PDB) was found 2.80 m below the surface.

The late Glacial climate evolution is deduced from a 4.58-m core (Fig. 1) whose detailed analyses are given elsewhere[51]. Figure 3 shows the stable isotope and diatom data. The diatom flora, of fresh to mesosaline water of the Na^+-CO_3^{2-} type, from a neighbouring core have been previously discussed[52]. Sudden peaks of the planktonic form *Cyclotella stelligera* var. *glomerata* reflect abrupt influxes of dilute ground water[52]. High absolute diatom contents coincide with high percentages of freshwater planktonic species (mainly *Melosira ambigua, M. granulata* and varieties), and indicate stages of relatively deep and dilute waters. The diatom influx was lower during phases of shallow saline waters. Very low diatom contents associated with bad frustule preservation (between ~12 and 11 kyr, for example) are probably the result of partial dissolution under fluctuating, ephemeral saline conditions[52].

At the base of the core, a calcareous diatomite could not be reliably dated, even by AMS, because of obvious traces of aquifer diagenesis on the carbonates, and despite the presence of a few millimetre-sized charcoals which are highly vulnerable to impregnation by hydrosoluble organic matter[51]. An episode more arid than today is registered by an overlying pure aeolian sand.

A sudden groundwater influx occurred before 12 kyr, and led to shallow saline conditions, with aeolian sand still predominant in the sediments. A second isotopic dilution is registered at ~12 kyr, and coincides with the base of a calcite-rich (15-50% of bulk sediment[51]) sedimentary episode. A water body, possibly ephemeral as suggested by the presence of the ostracod *Heterocypris salinus* and the bad preservation of diatom valves, persisted up to ~11 kyr under highly evaporative conditions. A new rise in the aquifer is recorded at 10.9-10.6 kyr. The isotope concentration then increased and reached the maximum value observed in the section at ~10.3 kyr. Diatoms show that generally dilute open-water conditions persisted up to that date, however, probably because of seepage of heavy solutions through the permeable lake bottom which may have regulated the salinity, as in the case of Lake Chad today[46,53]. At ~10 kyr, ~300 years later than the maximum isotope concentration, diatoms indicate a brief episode of very shallow saline-alkaline conditions. This is attributed to the leaching, by local rainfall or groundwater influx, of a highly soluble Na^+ carbonate crust deposited during a short but marked dry phase between ~10.3

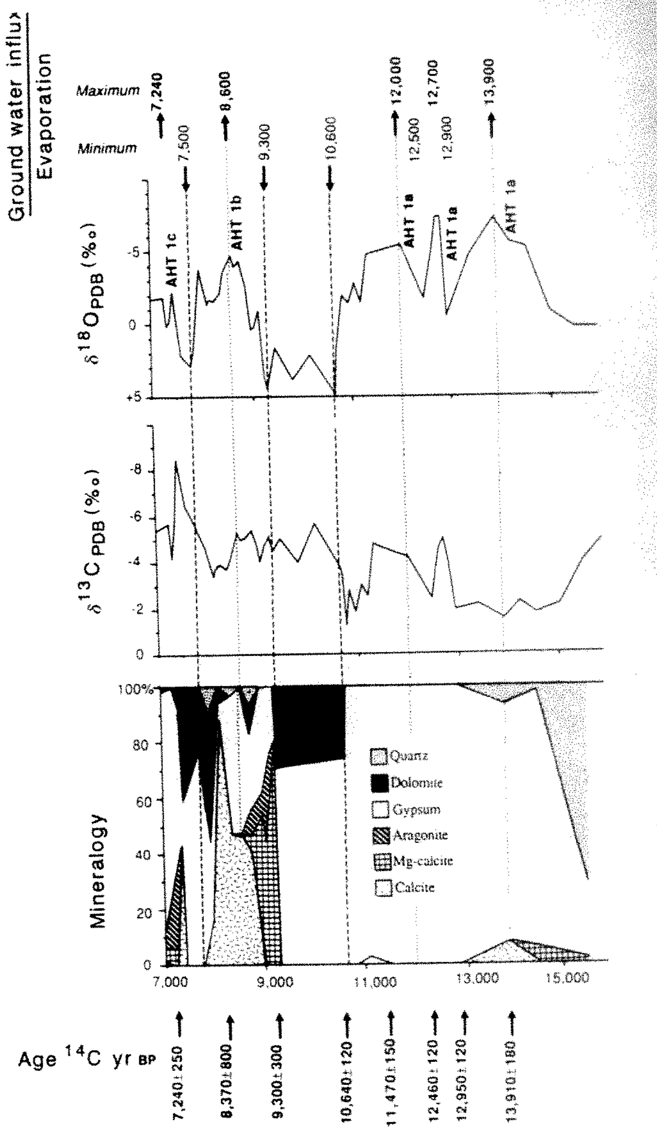

FIG. 2 Palaeohydrological indicators plotted against ^{14}C ages (16–7 kyr BP) for Site 1 (Sebkha Mellala, Algeria). Bottom, Mineralogy (XRD peak areas) of bulk sediment (biological remains excluded). Middle and top, Stable isotope contents of inorganic carbonates (fraction <80 μm) normalized to calcite[31] ($\delta^{13}C$(‰) = $[(^{13}C/^{12}C)_{sample}/(^{13}C/^{12}C)_{standard}] - 1$; $\delta^{18}O$ defined similarly). Arrows at the top mark the direction of the major hydrological events.

and 10 kyr. From ~9.7 kyr, the establishment of an early Holocene freshwater lake is registered first by a sharp peak of *Cyclotella stelligera* var. *glomerata*, increased diatom content and salt dilution, and then by a sudden stable isotope decrease. The hydrological turnover peaked at ~9.2 kyr when the calcite sedimentation was replaced by the accumulation of a diatomite almost free of carbonate. The freshwater lake persisted until ~8-7 kyr when the salinity began to fluctuate. Calcite reappears in the sediments at ~6.4 kyr. The top of the sequence records several hydrological fluctuations, including a sudden rise of the aquifer at ~4 kyr.

During the last deglaciation, two major phases of hydrological changes, ≤12 kyr (AHT1a) and ~9.7-9.2 kyr (AHT1b), are recorded in the Bougdouma core, bracketing a period of generally high evaporative conditions. During the Younger Dryas, however, there was a brief but clear humid phase dated from ~10.7-10.3 kyr. This is also recorded in individual interdunal depressions along the northwestern margin of Lake Chad[15,52] and was of regional extent.

Timing of the major climate events

The hydrological settings of our selected sites makes their hydrology and sedimentology dependent on the local rainfall. The two lacustrine records illustrate the extreme rapidity of the climate fluctuations that occurred over the Sahara and the Sahel during the last major arid-humid transition. The shifts from arid to humid conditions occurred in a few centuries, possibly in a few decades. Abrupt climate changes occurred at both sites at >12 (AHT1a) and at ~9.3 (AHT1b) kyr, with a reversal (H-A) centred on 10.5-10 kyr (Fig. 4). Both the northern and southern margins of the desert have thus experienced periods of excess input before 12 kyr, and probably since ~14 kyr. Our

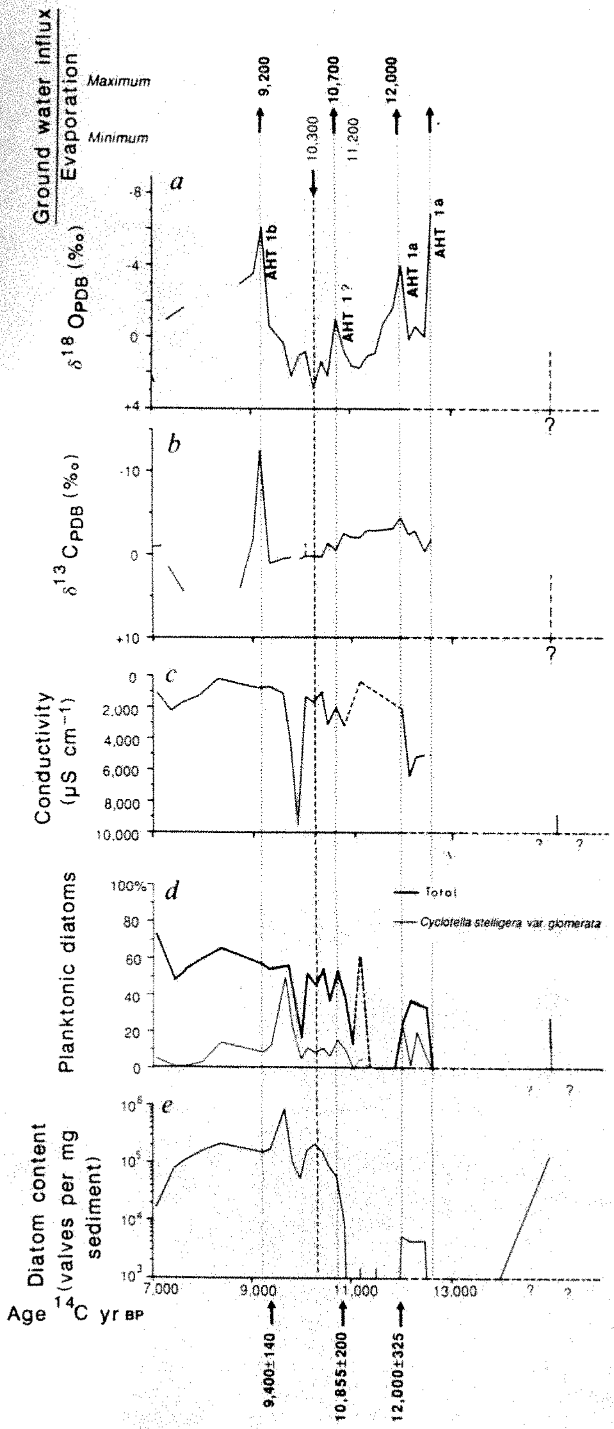

FIG. 3 Palaeohydrological indicators plotted against ^{14}C ages (16-7 kyr BP) for Site 2 (Bougdouma, South Niger). *a*, *b*, Stable isotope contents or inorganic carbonates (fraction <80 μm). *c*, Diatom-inferred water conductivity based on transfer function (refs 37, 38, and F.G. unpublished data). *d*, Relative percentages of planktonic diatoms. *e*, Sediment diatom content. The results in *c* and *d* are uncertain between 12 and 11 kyr owing to partial selective dissolution. Arrows at the top mark the direction of the major hydrological events.

data agree with previous data documenting the presence of early Holocene lakes in the northern Sahara[27,28,54], and do not support the hypothesis of a progressive re-establishment of wet conditions from the Equator to the Maghreb between 13 and 6 kyr[22,23].

Relationships to global climate change

Although stratigraphic uncertainties still exist, a comparison between our African sequences and the Atlantic and European records (Fig. 4) suggests that common factors have controlled the major changes in the ocean and atmosphere dynamics at low and high latitudes during the last deglaciation. The principal steps of the arid-humid transition, AHT1a and AHT1b (Figs. 4*c–e*), seem to have occurred at the same time as two intervals of rapid sea level rise deduced from coral-reef drilling and described as meltwater pulses 1A (12 kyr) and 1B (9.5 kyr)[6] (Fig. 4*h*). They coincide with the latter part of Termination 1A, and with Termination 1B as defined from deep-sea ^{18}O records[2-5] (Fig. 4*f*, *g*). Our chronology is also consistent with changes in the mean annual air temperature in Britain (reconstructed using beetle remains) which show two abrupt rises at ~13–12.2 kyr and ~10.2–9 kyr[55] (Fig. 4*b*), and with the European subdivisions based on cold-warm oscillations[56,57,34,35] (Fig. 4*a*). In both African sites, the phase of maximum aridity falls in the cold European Younger Dryas chronozone.

In the northern Sahara, the beginning of the first step (AHT1a) at ~14.5 kyr corresponds to the first signal of Termination 1A in the North Atlantic[2,20] and to the first appearances of hydro-thermophilous species in the pollen records from southwestern Europe[58]. The phase of maximum aridity started at ~10.6 kyr during the first part of the European Younger Dryas, and ended at ~9.3 kyr when warm conditions were fully re-established in Europe (Fig. 4*b*, *c*). These changes in rainfall, of Mediterranean or Atlantic origin, may have also influenced the vegetation of southwestern Europe.

In the Sahel, the interval 12–10 kyr corresponds with generally high evaporative conditions (Fig. 4*d*). The maximum aridity recorded at Site 2 between 10.3 and 10 kyr seems to match a maximum in the ^{18}O content of foraminifera and a minimum

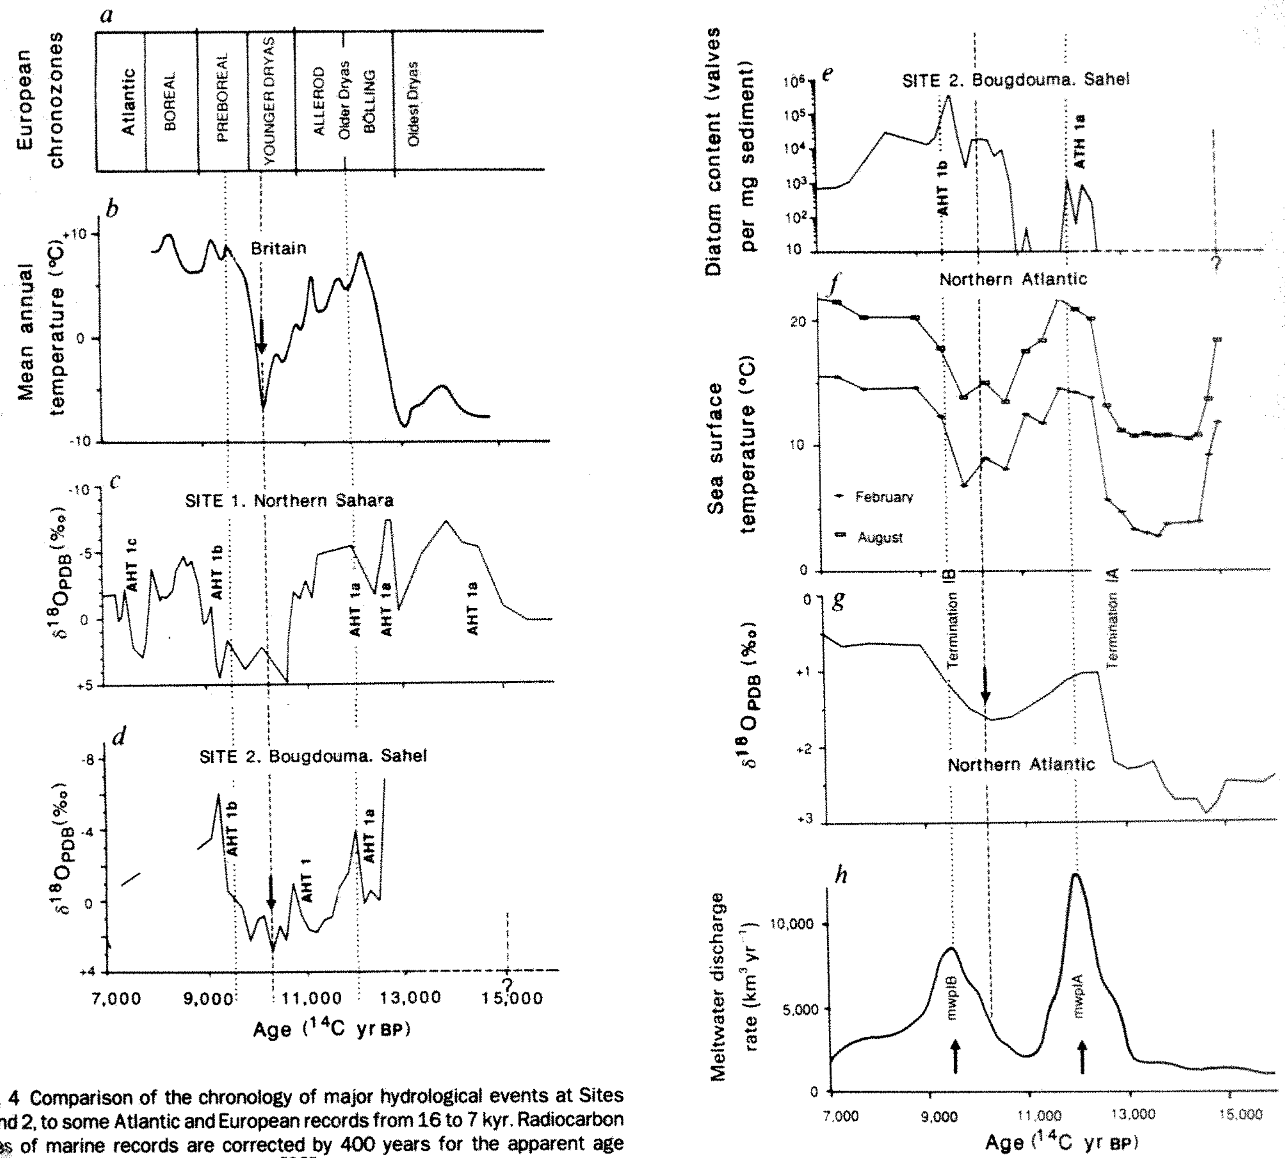

FIG. 4 Comparison of the chronology of major hydrological events at Sites 1 and 2, to some Atlantic and European records from 16 to 7 kyr. Radiocarbon ages of marine records are corrected by 400 years for the apparent age of sea water. *a*, European chronology[56,57]. *b*, The mean annual air temperature in Britain estimated from beetle remains[55]. *c*, Oxygen isotope profile of inorganic carbonate at Site 1, as an indicator of the ratio of groundwater influx to evaporation. *d*, Oxygen isotope profile of inorganic carbonate at Site 2, as an indicator of the ratio of groundwater influx to evaporation. *e*, Sediment content in the freshwater planktonic diatom *Cyclotella stelligera* var. *glomerata*, as an indicator of sudden rises of the aquifer[52]. *f*, The record of February and August sea surface temperature from the AMS ^{14}C-dated core SU81-18 located offshore of Portugal based on a palaeontological transfer function (ref. 4, and L. D. Labeyrie, personal communication). *g*, Oxygen isotope record of *G. bulloides* from core SU81-18 located offshore of Portugal[4]. *h*, The rate of the glacial melt water discharge calculated from Barbados sea level curve[6]. mwp = melt water pulse.

in sea surface temperature in the ocean core SU81-18[4], and the minimum mean air temperature in Britain[55] (Figs. 4*b*, *d*, *g*). In contrast with Site 1, however, sudden reversals are observed at Site 2, as in neighbouring sites[15,52], during the interval 12-10 kyr. A humid episode, from ~10.7 to 10.3 kyr, started in phase with the abrupt termination of the Younger Dryas recorded in Greenland ice cores[59]. Modern rainfall on the Sahel is statistically correlated with global SST anomaly patterns[60]. In the North Atlantic (core SU81-18) (ref. 4 and L. D. Labeyrie, personnel communication), the general drop in SST between 12 and 10 kyr is not monotonic (Fig. 4*f*). An increase of August SST observed from 10.7 to 10.3 kyr might be associated with the synchronous Sahelian humid phase.

Discussion

Major climate changes in North Africa during the last deglaciation seem to be in good chronological agreement with events deduced from deep-sea sediments, ice cores and European climatology. This indicates that the North African climate is largely subject to global (oceanic) control. The effects of cold Laurentide Ice Sheet melt water on the North Atlantic dynamics[8,20,21] have been invoked to explain the reduction in monsoon rainfall on the Sahel during the Younger Dryas[19]. But this does not account for the hydrological evolution at Site 1 because it is supplied by precipitation on the M'zab and on the Saharan Atlas Mountains, and is therefore difficult to attribute to a monsoonal climate. Nor does it explain the brief, but well defined, humid phase from ~10.7 to 10.3 kyr at 13-15° N, which shows that the concept of a unique recession synchronous with the Younger Dryas cannot be applied to the tropical latitudes of the Sahel. Other minor factors and feedbacks have to be investigated to explain the abrupt climate changes in this region between 11 and 10 kyr. Furthermore, the apparently variable timing of these events calls into question the notion that the Younger Dryas was a global event.

The principal factor inducing rainfall changes over Saharan and sub-Saharan Africa seems to have been the evaporative power of the atmosphere over the major production zones of air moisture. The atmospheric vapour made available by the global warming was distributed over Africa in response to several mechanisms: monsoon, squall lines, westerlies and Mediterranean depressions. We are now investigating the efficiency of air conveyors capable of carrying the vapour masses onto the African continent, especially in the central Sahara where the relative contributions of these effects may have varied during the year. Detailed surveys of laminated sediments are necessary to refine the seasonal variations for coupled atmosphere-ocean general circulation models. Such investigations are expected to reveal whether the different latitude belts of the Sahara and the Sahel could have been influenced by several distinct rainfall seasons during each year in the humid periods recorded by lacustrine events. □

Evidence for interaction of different eukaryotic transcriptional activators with distinct cellular targets

Katherine J. Martin*, James W. Lillie* & Michael R. Green*

Department of Biochemistry and Molecular Biology, Harvard University, 7 Divinity Avenue, Cambridge, Massachusetts 02138, USA

The adenovirus E1a protein (E1a), a potent transcription activator, contains a transcriptional activating region. Compared with previously described cellular and viral activators, E1a's activating region has unusual structural properties. It seems that E1a's activating region interacts with a cellular target not required for the function of transcriptional activators with 'acidic' activating regions. By contrast, the target of an acidic activating region is required both by acidic activators and by E1a. It is proposed that the cellular target of E1a's activating region is an 'adaptor' that allows E1a to interact with the basic transcriptional machinery.

THE 289-amino-acid E1a protein is required for the efficient expression of early viral genes[1-3]. Recent experiments provide evidence that E1a functions at the promoter and has the two essential properties of typical cellular activators: amino acids 121-223 contain both a promoter-binding region that directs E1a to its target promoters and a transcription activating region[4].

The transcription activating region of E1a[4] fused to the DNA-binding domain of GAL4 (amino acids 1-147)[5] increases transcription 200-fold from a core promoter bearing GAL4 binding sites. In contrast, this GAL4-E1a fusion protein does not activate transcription from a core promoter lacking GAL4 sites. The activating region revealed by these experiments is also required by the full-length E1a protein to activate an early viral promoter. Mutations that disrupt E1a's activating region can be rescued by the addition of a heterologous acidic activating region. Thus, E1a's activating region satisfies all the criteria used to define the activating regions of typical cellular activators.

Activating regions of several transcriptional activators have been mapped and grouped loosely into classes on the basis of their amino acid compositions. Activating regions defined to date are rich in acidic residues (GAL4, GCN4, VP16), glutamines (Sp1) or prolines (CTF/NF-I) (see ref. 6 for a review).

The acidic activating regions have been characterized most extensively. Studies of intact GAL4 and GCN4 show that the strength of an acidic activating region decreases only gradually upon deletion[7-9]. Analysis of the weak activating region of GAL4, region I, and activating regions generated at random from fragments of *Escherichia coli* DNA have verified the importance of acidic residues[10-13] but, in general, single amino-acid substitutions have little effect. These results suggest that activating regions are not highly structured, although some elements of structure are important for activity[10,11,14].

Although different acidic activating regions share no common sequence, they can substitute for one another and probably have a common cellular target[14]. Overexpression of an acidic activating region, for example, can inhibit the function of another acidic activator[11,15,16]. This inhibition, termed 'squelching', is thought to result from titration of the cellular target of the activating region. Accordingly, stronger activators inhibit (squelch) more effectively than weaker ones[11]. Overexpression of an intact activator can also have an inhibitory effect as a result of 'self-squelching'[14].

Here we present the results of mutational studies of E1a's activating region, revealing its unusual structural features. We also present squelching experiments indicating that the activating region of E1a interacts with a cellular target different from that of acidic activating regions.

Activating region of E1a

Boundaries. Our previous study showed that sequences of E1a between amino acids 139-223 comprise an activation region[4]. To define the boundaries of this region, we constructed derivatives of the previously described GAL4-E1a fusion protein which consists of amino acids 121-223 of E1a[4]. Figure 1 shows that the N-terminus of the activating region lies between amino acids 140 and 142: progressive N-terminal deletion to amino acid 140 resulted in a modest reduction in activity relative to intact GAL4-E1a. A drastic decrease in activity was observed on further deletion to amino acid 143. Activity was completely eliminated by deletion to amino acid 147. Site-directed mutagenesis of the two acidic residues at positions 140 and 141 shows that these positions are not critical for activation by E1a (see below). Thus, the N-terminal boundary of the activating region of E1a is located between amino acids 141 and 142.

Figure 1 also shows that the C-terminus of the activating region lies between amino acids 178 and 173: progressive C-terminal deletion to amino acid 178 did not decrease activity, whereas further deletion to amino acid 172 completely eliminated activity. We conclude that the core of the activating region has discrete boundaries and lies within E1a amino acids 141 and 178.

Sequences required for activation. The boundaries of the activating region indicate that it is contained within E1a region 3, a stretch of amino acids highly conserved among different adenoviruses[17] (Fig. 2*a*). To confirm the importance of these conserved amino acids for the function of the activating region, we constructed GAL4-E1a derivatives that contain single or multiple amino-acid substitutions. Figure 2*b* shows that with one exception (substitution of an arginine for the aspartic acid at position 168) mutation of one or more of the conserved amino acids disrupted the function of the activating region. With one exception (substitution of a cysteine for the tyrosine at position 159), mutations of the non-conserved amino acids had no effect.

Amino acids of all classes are conserved (Fig. 2*a*). Of the conserved amino acids, three are acidic, three are basic, and eighteen are uncharged. Mutational analysis (Fig. 2*b*) indicated that acidic, basic and neutral amino acids all contribute to form the E1a activating region. For example, basic amino acids at positions 160, 161 and 177, and neutral amino acids at positions 151, 154, 157, 165, 169, 170, 171 and 174 are all important for activity.

It was of particular interest to determine whether acidity is a determinant of the activating region of E1a. Substitution of acidic residues at positions 140 and 141 had little or no effect on activity. Changing the aspartic acid at position 168 to a basic residue did not substantially reduce activation. Substitution of a glycine for a conserved glutamic acid residue at position 148 (conserved in five of the six adenoviruses) reduced activity fivefold, whereas substitution of an alanine for the invariant aspartic acid at position 145 (conserved in all six adenoviruses) decreased activation fortyfold. Substitution of a glutamic acid for this aspartic acid reduced activity threefold, indicating that the role of this amino acid is not to provide negative charge *per se*. In summary, although at least one acidic residue (aspartic acid 145) is essential, net negative charge is not a determinant of E1a's activating region.

---

* Present address: Program in Molecular Medicine, University of Massachusetts Medical Center, 373 Plantation Street, Worcester, Massachusetts 01605, USA.

Four of the conserved amino acids within the activating region are cysteines. These cysteines are the ligands of a metal binding site ('Zn finger') that is required for function of the E1a protein[18]. We find that these cysteines are essential for the function of E1a's activating region: changing one, two, or all four cysteines to alanines eliminated activity (Fig. 2*b*). As model studies have shown that the cysteine residues of Zn fingers are required for metal binding[19,20], we conclude that the binding of a metal ion is essential to the formation of the activating region.

Representative activating region mutants were tested for the stability of their protein products; each was expressed comparably to GAL4–E1a (Fig. 2*c* and data not shown). The small variations observed (less than threefold) cannot account for the large differences in activation. From the sum of these results we conclude that the E1a activating region is not acidic, is highly structured, and includes an essential metal-binding site.

Cellular target of the activating region of E1a

Inhibition by wild-type E1a. The significant structural differences between the activating region of E1a and those of other proteins, suggested that E1a might interact with a unique cellular target. To investigate the nature of this target we performed squelching experiments similar to those that have been carried out with other activators[11,14,21].

GAL4–E1a can efficiently activate the GAL4–E1b TATA reporter plasmid, whereas wild-type E1a cannot[4]. Presumably, this is because wild-type E1a is not efficiently directed to this synthetic promoter. We could therefore use wild-type E1a to compete with GAL4 derivatives for the target of its activating region. High levels of E1a inhibited transcription directed by the GAL4–E1a activator (Fig. 3*a*). In contrast, activation by strong (GAL4–VP16 and GAL4–regII) or weak (GAL4–regI) acidic activators was either unaffected or not significantly inhibited by coexpression of E1a (Fig. 3*a*). These results suggest that the activating region of wild-type E1a protein competes for the target of the identical activating region carried by GAL4–E1a. They further suggest that E1a's target is not required by the acidic activators, regions I and II of GAL4 or VP16.

Immunoprecipitation and immunoblot experiments indicate that the various GAL4 derivatives (GAL4–E1a, GAL4–VP16, GAL4–regII and GAL4–regI), which contain the same 147 N-terminal amino acids, were expressed at comparable levels (data not shown; see refs 4, 15). Moreover, when the amount of transfected DNA encoding the activator was reduced nearly 1,000-fold, the same specificity of inhibition was observed (see Fig. 6). Thus, the specificity of inhibition cannot be accounted for by variations in the levels of the different activators.

A prediction of these results is that GAL4–E1a would not be able to activate transcription in cells that express high levels of wild-type E1a. Figure 3*b* shows that in 293 cells, GAL4–VP16 but not GAL4–E1a can activate transcription from the GAL4–E1b–TATA reporter.

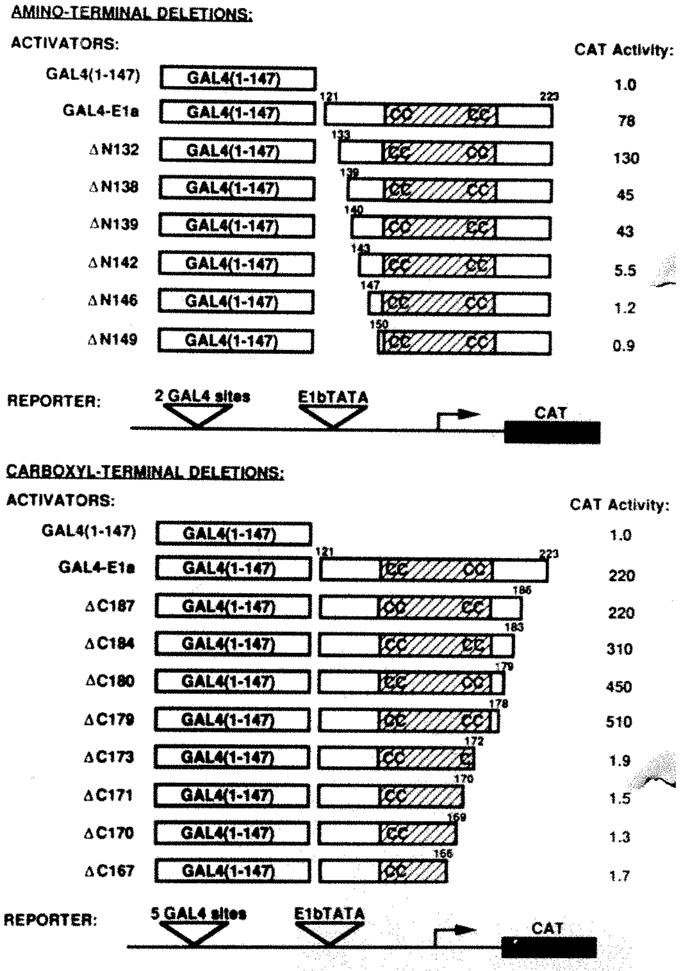

FIG. 1 The E1a transcriptional activating region lies between amino acids 140 and 178. A reporter CAT plasmid containing a core promoter (E1b TATA box) and two or five GAL4 binding sites was cotransfected with a plasmid encoding an activator protein. Relative CAT activity was measured and is indicated next to the diagrammed activators. The reporter plasmids are diagrammed below the sets of activators.

METHODS. Each GAL4 binding site is the 17-base pair (bp) oligonucleotide (MH100) previously described[33] and is inserted immediately upstream of each target promoter as indicated. The E1b TATA promoter contains an oligonucleotide comprising the E1b TATA box (5'-AGGGTATATAATG-3') inserted immediately upstream of the *CAT* gene in pSP72. GAL4 (1–147) is expressed from plasmid pSG147 or pSG424 (ref. 15). GAL4–E1a (pSGE1a) is E1a amino acids 121–223 fused in frame to the C-terminus of GAL4 (1–147), and was constructed by linking the *Cla*I–*Xba*I fragment of an adenovirus 5(Ad5) E1a 13S cDNA plasmid[34] downstream of GAL4 (1–147). GAL4–E1aΔN132, GAL4–E1aΔN138, GAL4–E1aΔN139, GAL4–E1aΔN142 and GAL4–E1aΔN146 are progressive 5' *Bal*31 deletions of the 13S cDNA *Cla*I–*Xba*I fragment, fused in frame to GAL4 (1–147). The GAL4–E1aΔC deletions are progressive 3' *Bal*31 deletions of the 13S cDNA *Cla*I–*Xba*I fragment, fused in frame to GAL4 (1–147). Unless otherwise stated, 2 μg per plate each of the reporter and activator plasmids were transfected by the DEAE dextran technique[35] into chinese hamster ovary (CHO-DUKX) cells grown on plates with a diameter of 10 cm. Cells were maintained below 50% confluency in α-MEM plus nucleotides and were split 1:8 24 h before transfection. Unless otherwise stated, 48 h post-dimethylsulphoxide shock cells were collected and assayed for CAT activity as described[36]. After autoradiography of the separated acetylated chloramphenicol forms, spots were excised and quantitiated by liquid scintillation counting. All assays presented have been repeated at least three times with comparable results.

Sequences required for inhibition. If the inhibition is due to squelching, then the sequences required for inhibition should be identical to those required for activation. To delineate the E1a sequences required for inhibition, we used as inhibitors the GAL4–E1a derivatives described above and assayed expression levels (Fig. 2*c*). We used a reporter chloramphenicol acetyl transferase (CAT) plasmid that contained six LexA sites upstream of the E1b–TATA box and was therefore activated by LexA–E1a but not by GAL4–E1a. The LexA–E1a activator contains the DNA-binding domain (amino acids 1–202) of the *E. coli* LexA protein fused to E1a (amino acids 121–223) (Fig. 3*c*).

Mutations within the E1a activating region, including the metal-binding site, reduced the ability of GAL4–E1a to inhibit LexA–E1a function. In contrast, mutations outside the E1a activating region did not affect inhibition by GAL4–E1a. Significantly, the degree to which each mutated activating region inhibited activation correlated with the strength of the mutated activating region. The cysteine mutations, for example, which completely eliminated activation (Fig. 2*b*), also completely eliminated inhibition (Fig. 3*c*). The E1a mutation 145A, which caused an intermediate level of activation (Fig. 2*b*), also caused an intermediate level of inhibition (Fig. 3*c*). We have tested all mutations in Fig. 3*a* that decrease activation and the rank order

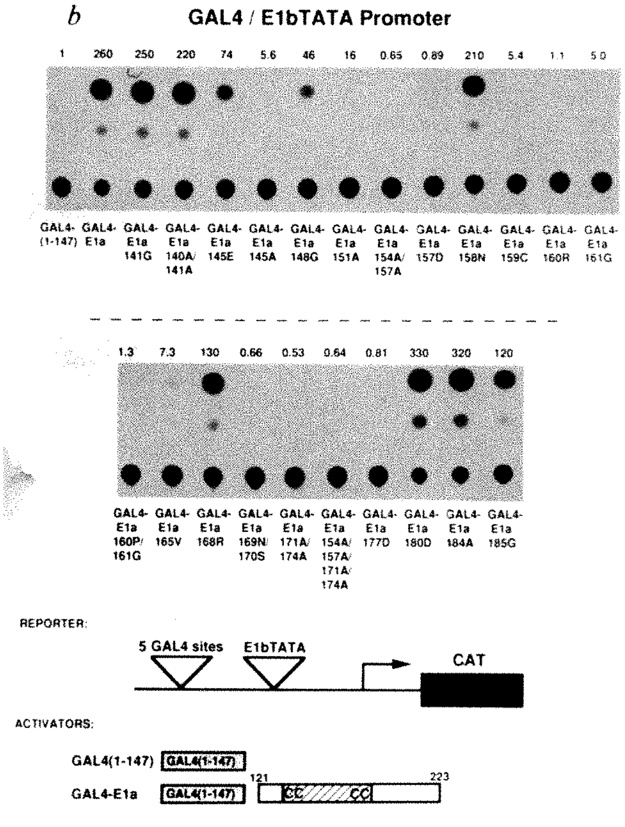

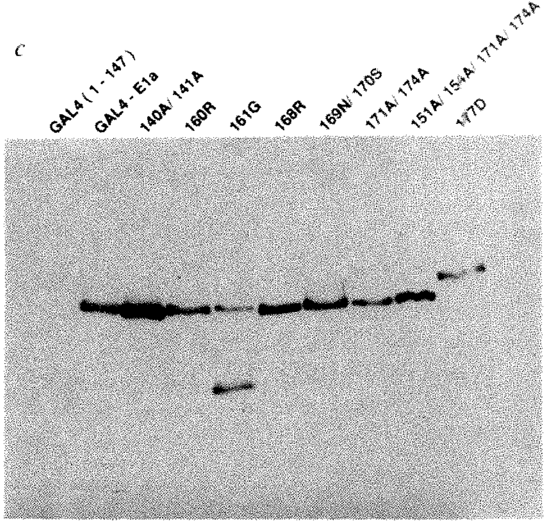

FIG. 2 Effects of amino-acid substitutions within Ad5 region 3. *a*, Region 3 amino-acid sequences (single-letter code) of six different adenoviruses[37,38]. The shaded regions represent those amino acids that are either strictly conserved in at least five of the six adenoviruses, or that have undergone conservative changes. The numbers below the sequences refer to the amino-acid position of Ad5. The bold Cs beneath the sequences indicate the positions of the four cysteines that chelate Zn^{2+}. The letters above the adenovirus sequences represent single, double and quadruple amino acid hanges we have constructed in Ad5 E1a region 3. Letters located above he mutated amino acid represent the residues that have been substituted. nes connecting letters indicate that multiple amino-acid substitutions have een made within the same molecule; circles that include more than one tter indicate that all enclosed substitutions were made in the same molecule. Letters not connected by lines or circled together represent single-residue substitutions. Those substitutions that had a greater than threefold effect on the ability of GAL4–E1a to activate transcription from a promoter containing GAL4 sites are circled. *b*, Transcriptional activity of mutant GAL4–E1a proteins. A reporter CAT plasmid containing a core promoter (E1b TATA box) and five GAL4 binding sites was cotransfected with a plasmid encoding an activator protein. Relative CAT activity was measured and is indicated above each lane of the autoradiogram. *c*, Expression levels of mutant GAL4–E1a proteins. ^{35}S-labelled GAL4–E1a derivatives from transfected COS cells were immunoprecipitated with an anti-GAL4 (1–147) antibody and fractionated on a polyacrylamide gel.

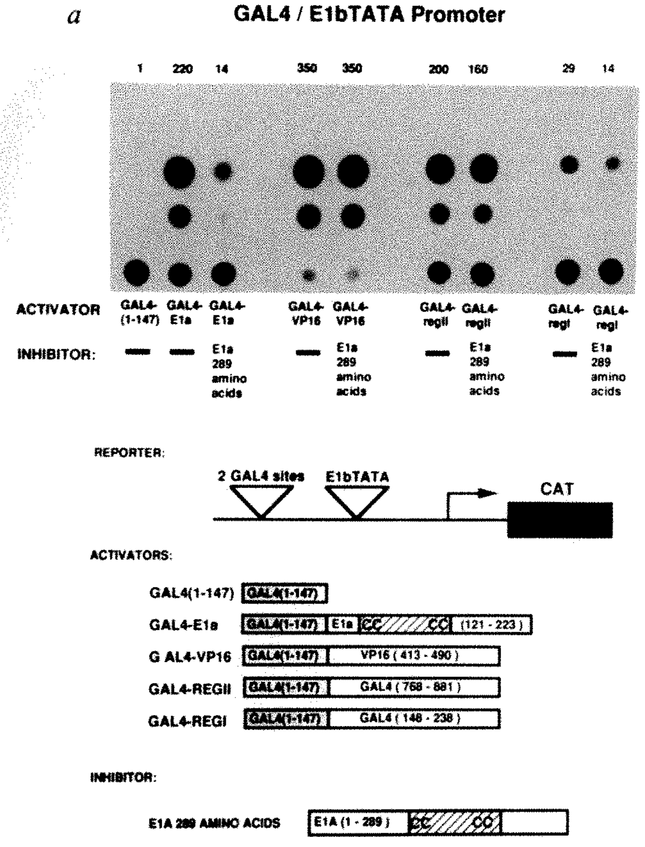
METHODS. *b*, GAL4–E1a180D contains a substitution at E1a amino acid 180 (G → D) and was constructed by replacing the *ClaI-XbaI* fragment of GAL4–E1a with the *ClaI-XbaI* fragment of the E1a activation mutant pH3G-13S-1098. All other mutations within region 3 were generated by site directed mutagenesis with mismatching oligonucleotides[39] or by random chemical mutagenesis[40]. *c*, COS cells were used to quantitate protein levels since higher levels of proteins are produced, facilitating detection. COS cells were transfected as described in the legend to Fig. 1. At 72 h post-transfection, cells were incubated with 200 μCi ml^{-1} of [^{35}S]methionine for 3 h. Labelled GAL4–E1a derivatives were immunoprecipitated[4] with an α-GAL4 (1–147) antibody (a gift of I. Sadowski) and fractionated on a 10% polyacrylamide gel. Unlabelled whole cell extracts were also prepared from COS cells cotransfected with plasmids encoding each activator and the GAL4–E1b-TATA–CAT reporter. These were assayed for CAT activity and results were identical to those obtained in CHO cells (data not shown).

in which they affected inhibition was the same as the rank order in which they affected activation (Fig. 2*b*, 3*c*, and data not shown). We conclude that the same E1a sequences are required for activation and inhibition. (This inhibitory effect is unrelated to the previously described E1a-mediated repression of enhancer-dependent transcription, which does not require conserved region 3 sequences[22-24].)

Figure 4 presents a control experiment which shows that coexpression of wild-type E1a with an E1a fusion protein (in this case LexA–E1a) did not alter the amount of fusion protein capable of binding to DNA. This assay made use of a reporter with a LexA site located between the TATA box of the SV40 promoter and a *CAT* gene. Proteins that bind to this LexA site inhibit transcription[35]. Under the identical conditions that resulted in a large inhibition by the wild-type E1a of LexA–E1a activation (Fig. 4, left panel), there was no change in the level of DNA binding by LexA–E1a (Fig. 4, right panel). At the level of LexA–E1a that was used (0.5 µg DNA), this binding assay was sensitive to changes in protein levels (Fig. 5, bottom panel of graph). Neither LexA–E1a nor wild-type E1a affected transcription from an SV40-*CAT* reporter lacking LexA sites, and wild-type E1a did not affect transcription from the SV40-LexA-*CAT* reporter (data not shown).



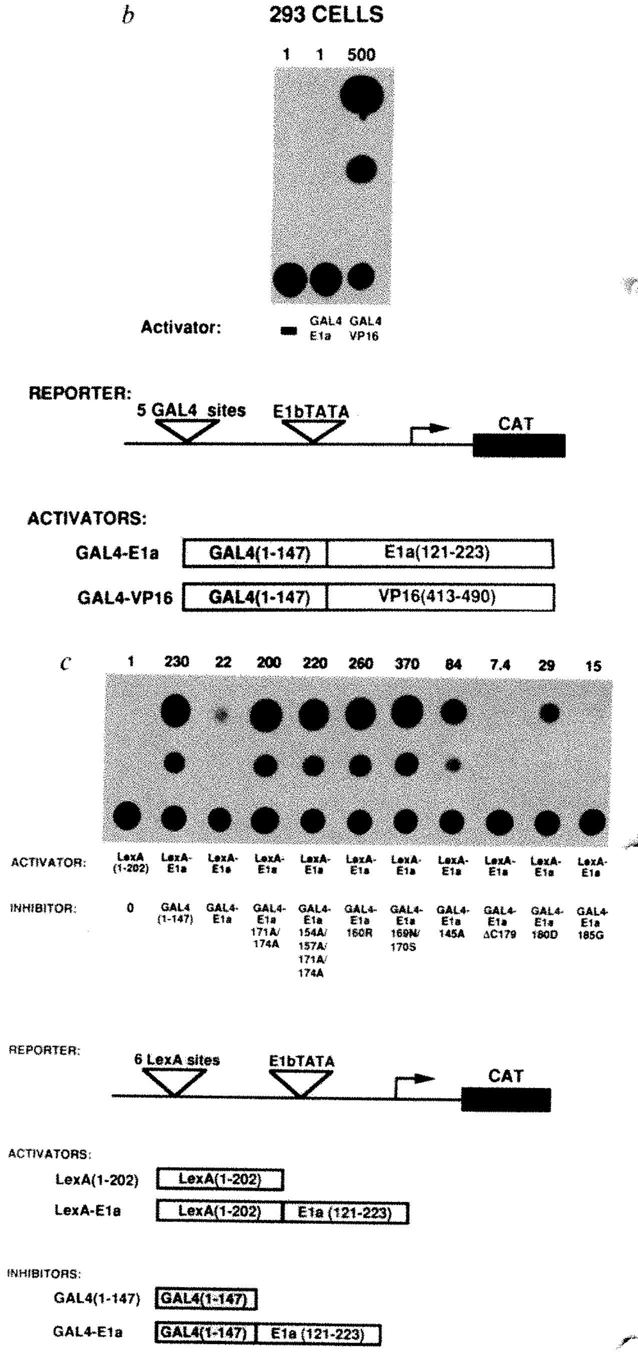


FIG. 3 Inhibition of transcription by E1a. *a*, Wild-type E1a. Reporter CAT plasmid (2 µg) containing a core promoter (E1b TATA box) and two GAL4 binding sites was cotransfected with 2 µg of a plasmid encoding a GAL4 derivative and, where indicated, 2 µg of either an E1a expression plasmid or the pSP64 (Promega) vector. Relative CAT activity is indicated above each lane. The structures of the target promoters and activator proteins are diagrammed below. *b*, 293 cells. The reporter diagrammed (1 µg) and 2 µg of the specified activator were transfected into 293 cells by the DEAE dextran technique[35]. In the absence of activator, 2 µg of vector was transfected. Cells were collected 72 h post-dimethylsulphoxide shock. *c*, GAL4–E1a and E1a mutants. Reporter CAT plasmid (1 µg) containing a core promoter (E1b TATA box) and six LexA binding sites was cotransfected with 40 ng of a plasmid encoding an activator protein and, where indicated, 1 µg of plasmid encoding an inhibitor protein. In the absence of inhibitor, 1 µg of vector was added. Cells were collected 72 h after DMSO shock.

METHODS. GAL4–regI is the weak GAL4 activating region fused to GAL4 (1–147) and is expressed from pSG238 (refs 5, 7). GAL4–regII is the strong GAL4 activating region fused to GAL4 (1–147) and is expressed from pSG236 (refs 5, 7). GAL4–VP16 contains the 78 C-terminal amino acids of the HSV1 VP16 protein fused in frame to the C-terminus of GAL4 (1–147)[15]. Wild-type E1a is the 289-amino-acid E1a protein expressed from a plasmid (pSP613S) that contains the E1a region of adenovirus type 2 (minus the 13S intron) inserted into pSP64 (Promega). The LexA–E1bTATA reporter (pL6EC; a gift from P. Broad) has a triplicated insert of a 41-bp *Xho*I fragment, which contains two LexA sites derived from the *colE1* promoter[41] in the *Xho*I site of the E1b TATA reporter. LexA (1–202) comprises LexA amino acids 1–202 and 12 amino acids coded for by a polylinker and is expressed from the plasmid pBXL1 (gift from P. Broad). This plasmid is analogous to pSG424 (ref. 42), but contains LexA (1–202) in place of GAL4 (1–147). LexA–E1a is E1a amino acids 121–223 fused in frame to the C-terminus of LexA (1–202) and was constructed by inserting the *Eco*RI-*Xba*I fragment of pSGE1a (GAL4–E1a) downstream of LexA (1–202), between the *Eco*RI and *Xba*I site of pBXL1.

Self-squelching of E1a derivatives. We next determined the effect of overexpressing a single E1a derivative. Figure 5 shows that increasing the amount of transfected DNA expressing either GAL4-E1a or LexA-E1a led at first to increased activation and subsequently to inhibition. The bottom panel of the graph confirms that the level of LexA-E1a protein correlated with the amount of transfected DNA. The intracellular level of LexA-E1a protein increased steadily over the course of the titration as assayed by its ability to bind *in vivo* to a LexA site located between the SV40 promoter and a *CAT* reporter gene[25]. Proteins that bind to this LexA site inhibit CAT expression. Expression from an SV40-*CAT* reporter that lacks LexA sites was unaffected by cotransfection of the plasmid expressing LexA-E1a (data not shown).

These results suggest that, as the intracellular concentration of the E1a derivative is raised, activation of transcription increases until all DNA sites or all activation targets are saturated. After that, overexpression of the E1a derivative reduces the level of activation as the unbound E1a derivative begins to sequester the activating target. Self-squelching by LexA-E1a and GAL4-E1a show that E1a squelching is not a consequence of the coexpression of two different E1a derivatives (for example, by formation of inactive heterodimers).

Cellular target of the activating region of VP16

Expression of the E1a activating region can inhibit transcription directed by GAL4-E1a or LexA-E1a but not by the acidic activating regions of GAL4-VP16, GAL4-regI or GAL4-regII (Fig. 3). This indicates that the target of the E1a activating region is not required for transcription directed by acidic activators. To address whether acidic activators use targets that are required for transcription directed by E1a, we asked whether VP16 can squelch E1a.

Figure 6 shows that, as expected, VP16 can compete for its own activation target: LexA-VP16 inhibited transcription activation by GAL4-VP16. The target of VP16's activating region is also required for activation by E1a: LexA-VP16 inhibited activation by GAL4-E1a. As with the full-length E1a protein, an E1a fusion protein competed for its own activation target (LexA-E1a inhibited GAL4-E1a), but did not inhibit transcription directed by the VP16 activating region. We are not merely observing an ability of the inhibitor to squelch any activator of equal or weaker strength than itself, as neither E1a nor LexA-E1a can squelch the relatively weak GAL4-regI, or GAL4-regII (Fig. 3*a* and data not shown). Thus, we conclude that E1a's activation target is not required by VP16, whereas VP16's activation target is required by E1a.

Discussion

Activating region of E1a. The activating region of E1a has relatively discrete boundaries and is inactivated by a number of single amino-acid substitutions. These essential amino acids are of several classes. Taken together, our mutagenesis experiments suggest that the E1a activating region is highly structured and that this structure is important for activity. It is likely that the metal-binding site, which is essential for function, has an important structural role. Metal-binding sites can allow proteins to form highly structured and essentially independent domains from a limited number of amino acids[20].

Many sequence-specific DNA-binding proteins contain metal-binding sites, termed Zn fingers[19,20,26]. It is not clear whether E1a's metal-binding site is involved in DNA binding. Although E1a is not a sequence-specific DNA-binding protein,

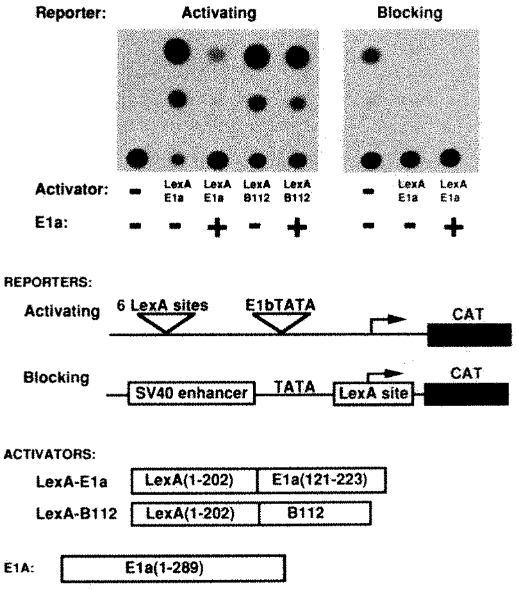

FIG. 4 *In vivo* DNA-binding assay. The diagrammed reporter (1 μg), 0.5 μg of the specified activator or vector DNA, and 1 μg of E1a expression plasmid or vector DNA were transfected into CHO cells. Cells were collected 56 h post-DMSO shock. The two panels represent transfections done in parallel with identical procedures, only the reporter DNAs differ. LexA-B112 (a gift from P. Broad) is LexA (1-202) fused at its C terminus to B112, which is an acidic amphipathic amino-acid sequence derived from random *E. coli* DNA that functions as an activator of transcription[10].

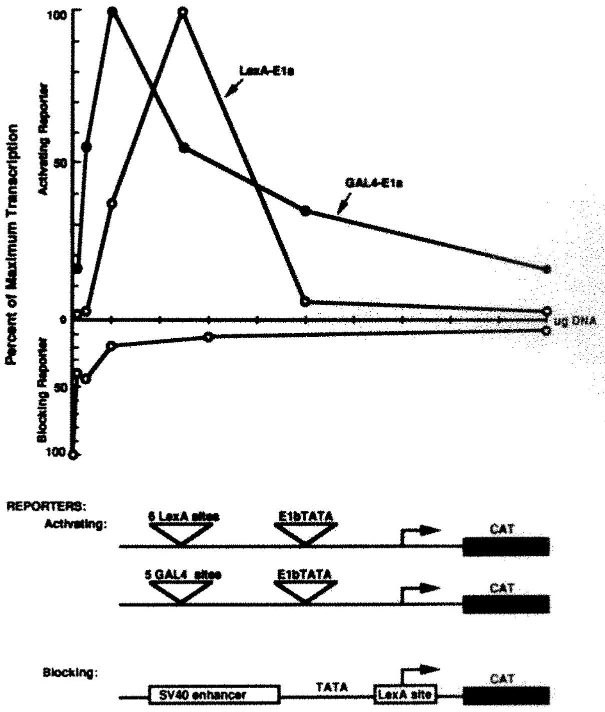

FIG. 5 High levels of either GAL4-E1a or LexA-E1a inhibits transcription activation. Activating reporter CAT plasmids (1 μg) containing a core promoter (E1b TATA box) and either six LexA sites or five GAL4 sites were cotransfected with varying amounts of plasmids encoding the appropriate E1a fusion protein, LexA-E1a (○) or GAL4-E1a (●). The total amount of DNA transfected was held constant by including an appropriate amount of vector DNA. Each mark on the x-axis represents 1 μg of activator DNA; a minimum of 100 ng and a maximum of 10 μg of activator DNA were transfected per 10 cm plate of cells. Cells were collected 72 h post-dimethylsulphoxide shock. Relative CAT activity was measured and is graphed as a percentage of the maximum level of CAT activity for each DNA titration. The data plotted below the x-axis are CAT expression levels from a cotransfection of the blocking reporter diagrammed, also called VV(X)CO[25], and varying amounts of DNA encoding LexA-E1a. Relative CAT expression levels are reported as a percentage of the level of CAT expression observed in the absence of LexA-E1a. The lower plot is an indication of the intracellular concentration of the LexA-E1a protein. Structures of the target promoters are diagrammed below.

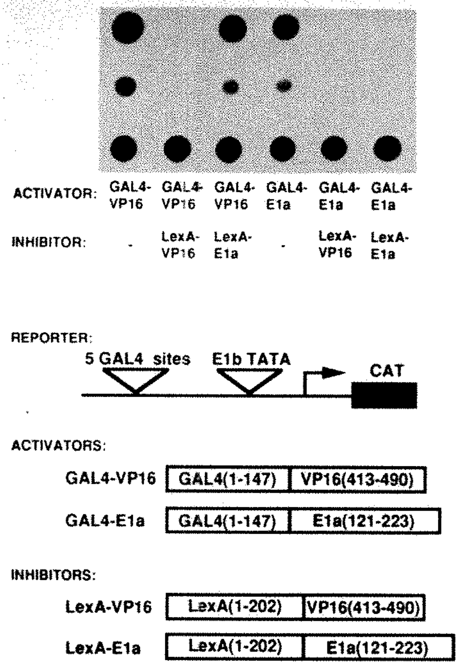

FIG. 6 Inhibition by VP16 and E1a transcriptional activating regions. A reporter CAT plasmid (1 μg) containing a core promoter (E1b TATA box) and five GAL4 sites was cotransfected with plasmids encoding an activator and, where indicated, an inhibitor protein. 3 ng of the GAL4-VP16 activator and 10 ng of the GAL4-E1a activator were used. The inhibitors were both used at a level of 3 μg.

METHODS. LexA-VP16 (gift from P. Broad) and contains the 78 C-terminal amino acids of HSVI VP16 protein fused in frame to the C-terminus of LexA (1-202) in the expression vector pBXL1. Cells were collected 72 h post-DMSO shock. CAT assays of the GAL4-E1a activators (lanes 4-6) were performed with 25-fold more cell extract than those of the GAL4-VP16 activator (lanes 1-3).

it may bind to DNA nonspecifically[27]. The E1a region responsible for DNA binding and its relevance to transcription remains to be determined. Berg[20] has pointed out that E1a's metal-binding site bears structural similarities to the metal-binding site of aspartate transcarbamylase, which is not a DNA-binding protein. The metal-binding site of aspartate transcarbamylase is at a surface involved in protein-protein interaction[28]. We favour the idea that the principal role of E1a's metal-binding site is to form a surface that interacts with other proteins.

Adaptors. We suggest that the inhibition observed at high concentrations of the E1a activating region is caused by sequestration of its cellular target. Our interpretation is like those reached in studies of other activating regions[11,14-16]. We recognize that neither our nor previous results prove the existence of a limiting cellular target, or that competition for it caused the inhibition. We cannot, however, think of an alternative interpretation that adequately explains these results. Moreover, our demonstration that there is specificity to squelching significantly strengthens this interpretation as it rules out the possibility that the inhibition is caused by cytotoxicity or a nonspecific inhibitory effect on transcription, for example.

We refer to E1a's target, inferred from these experiments, as an 'adaptor' because it is not required for transcription directed by acidic activators. E1a's target is therefore an auxiliary, rather than an essential, transcription component. In contrast, the target of acidic activating regions is required for transcription directed both by VP16 and by E1a. This could be explained if acidic activating regions directly interact with an essential transcription component. In fact, DNase I footprinting studies provide evidence for an interaction between an acidic activating region and the TATA-box binding factor, TFIID[29].

We imagine that E1a's adaptor binds to E1a and also interacts directly with the basic transcription machinery. For example, the adaptor may contain, in addition to an E1a binding surface, an acidic activating region. A precedent for such an adaptor is the viral VP16 protein, which contains a potent acidic activating region[15,16] and a second region that interacts with the cellular transcription factor Oct-1[30,31]. By itself, Oct-1 cannot activate transcription from a typical promoter containing a TATA box. The same promoter can, however, be activated by Oct-1 in the presence of VP16[32]. It is conceivable that other nonacidic activating regions, such as those rich in glutamines or prolines, may also act through specific adaptors. Such adaptors would explain how diverse protein motifs can all activate transcription through the same basic transcription components. □

Opaque spiral galaxies

Edwin A. Valentijn

European Southern Observatory and Kapteyn Astronomical Institute,
PO Box 800, 9700 AV Groningen, The Netherlands

SPIRAL-galaxy disks have long been thought to contain only a modest amount of light absorbing dust, meaning that they are transparent to their own starlight, and that observers see light from their far sides. This view was based on studies of the variation of the average surface brightness as a function of the galactic inclination along the line of sight in small samples of galaxies[1,2]. We[3] have digitized the photographic images of a carefully selected sample of about 16,000 galaxies and determined an extensive set of photometric parameters. These data allow a re-analysis of the effective transparency, using the measured surface brightness profiles for much larger, more strictly defined samples. Several tests provide evidence that the major parts of many spiral disks are opaque, and that in many cases perhaps only the outer layer of stars is observable. This invalidates most determinations of mass-to-light ratios. Various photometric properties point to an obscuring component with a larger exponential scale length than that of the stars, possibly composed of cool compact opaque clouds. This result diminishes the evidence for dark haloes around spirals, as inferred from rotation curves.

Classically, the extinction inside the disks of spiral galaxies is studied by selecting a group with supposedly similar intrinsic properties and analysing how various parameters change with the inclination relative to the line of sight, the inclination angle being derived from the observed axial ratio a/b. For a transparent disk the apparent total blue magnitude B is constant, whatever the inclination, but for an optically thick disk, B varies approximately as $B_{\rm obs} = B_{\rm face} + 2.5\,D \log(a/b)$, where $D \doteq 1$ for a fully opaque disk. The variation of the local surface brightness μ^B as a function of inclination is reversed. For the optically thick case, μ^B is constant with inclination because the observer will always see about one mean free path into the system. In the transparent case, the longer line of sight through inclined systems will brighten the apparent μ^B approximately as

$$\mu^B_{\rm obs} = \mu^B_{\rm face} - 2.5C \log(a/b) \qquad (1)$$

where $C = 1$ if there is no extinction at all.

Disney *et al.*[4] recently reviewed the weak evidence for transparency of spiral galaxies and pointed out that various standard models[1,2,5,6] correspond to values of C in the range 0.46–0.9 (semi-transparent to transparent). The models are based on Holmberg's original studies[1] of the relationship between the 'projected surface brightness' $\mu^B_{\rm proj}$ and axial ratio for a sample of 119 spiral galaxies. He measured the total magnitude within the $\mu^B = 26.5$ isophote together with the major and minor diameters a and b, and from these derived $\mu^B_{\rm proj} = B + 2.5 \log a^2$. Anticipating semi-transparent systems, he successfully fitted an 'absorbing screen' model to $\mu^B_{\rm proj}$ as a function of a/b. If disks are fully opaque, however, a is not expected to vary with inclination. This implies that the variation of $\mu^B_{\rm proj}$ with a/b can in fact represent the expected variation of B in the opaque situation. For axial ratios up to $a/b = 5$, Holmberg's original data points can be fitted quite well with an exclusive (opaque) $D = 1$ correction to B. With the thousands of data points from the ESO-LV survey (ref. 3), Holmberg's measurements of the regression of $\mu^B_{\rm proj}$ with a/b is confirmed, but this classical test, which for several decades has been thought to indicate that the disks of spiral galaxies are transparent, can be interpreted equally well using the optically thick model. The ambiguity arose because of the use of the average surface brightness to study a/b-dependent terms, but now measures of the local surface brightness are available.

Here I report tests using the diameter-complete sample of 9,381 late-type galaxies extracted from the ESO-LV survey, that is, a sample of galaxies for which full surface-brightness profiles have been measured. Three measures were used: the extrapolated central surface brightness $\mu_0^{B,\rm fit}$ found by fitting an exponential to the two-dimensional light distribution, the μ_0^B within a 1″ aperture converted from the measured surface brightness within an aperture of radius 5″, $\mu^B_{5''}$, and the observed surface brightness at the half-total-light radius μ_e^B. Table 1 lists the means of these three independently derived values of the central surface brightness for different morphological types. For pure exponential disk systems without a bulge, $\mu_0^B = \mu_e^B - 1.822$. Columns 4, 6 and 7 demonstrate the consistency between the three different techniques and column 5 shows the very small standard deviation of μ_0^B. A comparison of μ_0^B with the other two measurements shows that the presence of bulges in early-type spirals (types 1 and 2) increases the actual central flux by only ~0.3 m (m is relative magnitude); but results for these types could be affected by bulges. For the later types, no significant contribution from bulges is observed.

The key test, the analysis of the relationship between surface brightness and axial ratio, is presented in Fig. 1. This provides the strongest evidence that the disks of spiral galaxies are not transparent and, as the surface brightness at the half-total-light radius (diameter D_e) hardly brightens with a/b, this must be so for large parts of the disks. For different morphological types, equation (1) has been fitted to both μ_0^B and μ_e^B as function of $\log(a/b)$. The resulting coefficients, μ at $a/b = 1$ and C, are listed in Table 1. The central areas of all spirals of types 1–6 behave as would be expected for opaque conditions; this result was also found using the uncorrected $\mu^B_{5''}$. This condition seems to relax at the half-total-light radius of Sc and later types and at the centres of Sd galaxies. Beyond the half-total-light radius, any further radiation variation of C can be estimated using the distance-independent ratio D_{26}/D_e where D_{26} is the diameter

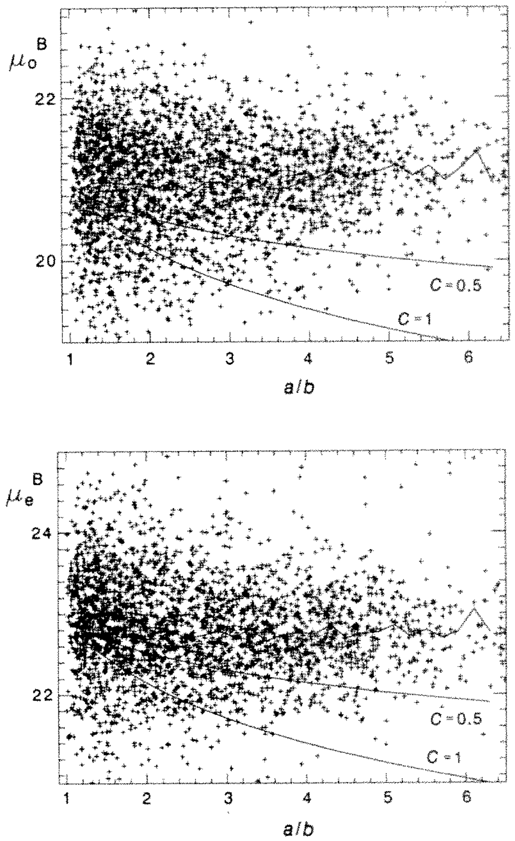

FIG. 1 The distribution of 2,639 type 2.5–5.0 (~Sb) galaxies in the surface brightness (left, at centre; right, at half-total-light radius) a/b diagram. The mean μ in a/b bins of 0.2 is indicated together with two curves representing the expected trend for transparent disks with $C = 1$ and $C = 0.5$.

at $\mu^B = 26$ isophote. The a/b dependency of this ratio is related to the variation in transparency between the two diameters. The ratio is roughly constant for equal transparency and the ratio increases with a/b for all situations of radially increasing C. For types 2–6, no significant variation of D_{26}/D_e with a/b is found, which implies that the C_{μ_e} values listed in Table 1 must also apply to the outer regions of these galaxies.

The formal statistical errors of the listed C values are very small (≤ 0.03) and the implications of the low values obtained are so crucial for understanding the contents of spiral disks that a detailed evaluation of the tests is necessary. First, the tests were repeated using only those objects for which a free fit indicated that they possess a perfect exponential light profile. This reproduced the C values within the uncertainties and makes it very unlikely that the result is affected by the presence of bulges, at least for types 3–10. Second, the position of D_e could depend on a/b. In general, however, for both transparent and opaque systems the definition of D_e precludes such a dependency. As a check, C values were determined using $\mu_0^{B,\mathrm{fit}}$, which resulted from a fit to the two-dimensional light distribution between $r = 5''$ and the 25th isophote. These values are insensitive to the actual location of D_e and reproduce those obtained from μ_e^B, within 0.03. Because for most systems D_e is located in the middle of the area used for the fit, this also confirms the small radial variation of C.

Finally, selection effects inherent in a diameter-selected sample[3] may have influenced the result. At fainter magnitudes the survey has a bias against bright μ_0 and low-a/b systems (Fig. 2). By reducing the total sample to 1,867 objects, with $\mu_B < 21$ for types 1–5 and $\mu_B < 22$ for types 6–10, these selection effects are avoided. This 'control' sample has a distribution of observed a/b ratios very close to that expected from a randomly acquired sample of intrinsically round disks. Moreover, it is most complete with respect to its selection criteria. As seen in Table 1, the control samples reproduce the C values from the total sample very well, also demonstrating that axial-ratio selection effects are not affecting the result.

Another way of visualizing the result, using the total sample, is by counting the number of objects that are positioned on the right side of the curve $\mu_{\mathrm{lim}} = 26$ in Fig. 2. An intrinsically round and face-on exponential disk galaxy will be a part of the sample if it lies to the left of this 'inclusion boundary'[3,7,8]. All 4,873 galaxies (52%) on the right side of this curve, if they were intrinsically round, passed that boundary because of inclination effects. As their a/b is known the surface brightness and/or the magnitudes of these galaxies can be adjusted to their face-on values. When a 'transparent' correction ($C=1$) is applied to μ_0^B, 36% remain on the right side, for a 'semi-transparent' correction ($C=0.5$, $D=0.5$) the fraction is 23%, whereas for the 'fully opaque' correction on B_T ($D=1$), it is only 9%. As the curve describes the prime selection effect of a diameter-selected sample, this demonstrates that the data fully match the selection effect for opaque spirals, whereas transparent systems would lead to a serious inconsistency.

The low C values for large radii also imply a rather modest dependency of isophotal diameters on a/b (contrary to ref. 5) This allows an independent check on the result, by analysing for which magnitude correction the scatter in the "absolute total magnitude intrinsic diameter" reduction is a minimum. For a subsample of 1,582 spirals a minimum scatter is found fo $D=0.85$. For simple models, $C=1-D$, and estimates of C_{1-D} calculated from D are listed in Table 1. Magnitudes that were not corrected for inclination ($D=0$, transparent) resulted in a r.m.s. scatter of 0.64, whereas for an opaque ($D=1$) correction the scatter was reduced to 0.47. This reduction is highly significant (8.5σ) and confirms that most parts of the disks are opaque.

The tabulated C values can be used as an overall diagnostic on the effective transparencies at different locations for different types and can be applied directly to estimate face-on magnitudes for inclined systems. If $C \leq 0.2$ for large parts of the disks, as found for Sb and Sc galaxies, very strong obscuration is implied, requiring a dramatic revision of the interpretation of the surface-brightness profiles. For the centres, detailed modelling indicates that negative C values can occur, due to extinction of the light originating from opaque layers by surrounding semi-transparent layers. The amazingly small variation of μ_0^B (refs 9, 10) is also confirmed (contrary to refs 11, 12) albeit with the refinement that the average μ_0^B becomes larger with increasing type, which for later types (7–10) is also correlated with larger M. For opaque

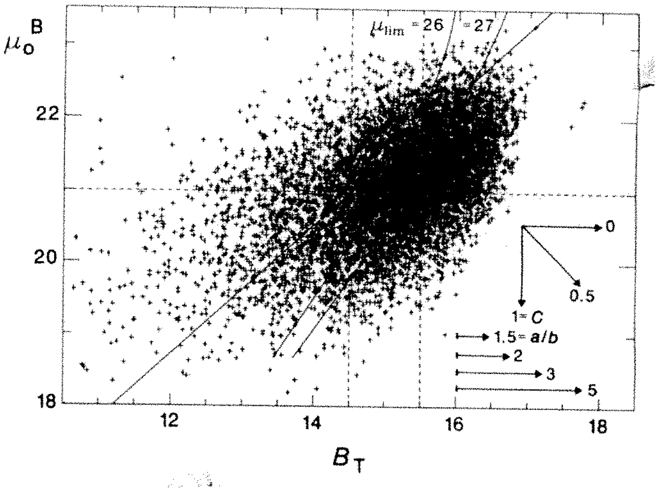

FIG. 2 A plot of central surface brightness against total magnitude for 8,061 spiral galaxies (type 0.5–8.5). Direct observational data, not corrected for inclination. The $\mu_{\mathrm{lim}} = 26$ curve represents the theoretical inclusion boundary for circular face-on exponential disks and corresponds to the 1′-diameter selection criterion of the survey. The vectors show how intrinsically circular disks move in the diagram for various transparencies (direction) and inclinations (amplitude). The positions of 4,873 galaxies to the right side of the $\mu_{\mathrm{lim}} = 26$ curve can only be understood if most of them represent inclined opaque disks. The straight line shows the observed regression for face-on circular disks. At fainter magnitudes the survey has a bias against bright μ_0 objects and low-a/b systems.

conditions, this small variation would result from a limited range of star-to-dust ratios for each morphological type, which on average should then also vary with type.

An observed value of $C = 0.2$ for large parts of Sb and Sc disks with a modest radial variation has even greater consequences. The observations cannot result from opaque layers with a small scale height compared to the stellar distribution, because the photometric properties of such disks would then be like those of transparent systems (μ_B decreasing with increasing a/b, contrary to the observations) and we would not even notice that we miss half of the starlight. A measurement of $C = 0.2$ at a particular radius could result from a two-layer situation in which 80% of the detected light originates from a fully opaque layer with optical depth $\tau \gg 1$ and the rest from a surrounding transparent layer. Calculations[13] also demonstrate that the effect of multiple scattering on dust grains can produce a C value around 0.2 in $\tau \gg 1$ disks. Models incorporating a $\tau \gg 1$ layer would predict constant surface brightness profiles, however, given the observed modest radial variation of C. This also applies to the models of ref. 4 where the absorption is thought to be due to cirrus-like distributed dust. Areas of equal surface brightness can indeed be found along the arms of various spirals and a flat profile is also seen in several central areas. But many exponential light profiles are observed in $C = 0.2$ disks. This implies that the detected light and its corresponding C should originate mostly from a single layer of well mixed stars and obscurers, with $\tau \approx 1.3$ corresponding to ~0.6 m total face-on extinction, in which case about half of the system would be detected when face-on and one-sixth when at 80° inclination. The radial exponential intensity distribution should then be related to the radial volume density of the stars (ρ_*), the volume density ρ_0, and cross-section σ_0 of the obscuring material by $I(r) \approx (\rho_*(r)/\rho_0(r)\sigma_0(r))(1-e^{-\tau})$. For a modest variation of τ this implies either a radially decreasing star-to-obscurers density ratio, or increasing σ_0, or both. In fact, the obscuring bodies must have the property $\tau = T\rho_0\sigma_0 = 1.3$, with T of the order of a hundred parsecs. This condition can be evaluated for all scales and the most reasonable match is with compact opaque clouds with, for instance, diameters of the order of 50 pc and $\rho_0 \approx 6\times10^{-6}\,\mathrm{pc}^{-3}$. These clouds should contain dust and stars that are in turn embedded in a sea of stars. As the distance to the galactic centres increases, the ratio of the volume density of the clouds to that of 'the sea of stars' should increase. The expected low temperatures for such clouds predict a substantial flux of submillimetre-wavelength radiation from Sb and Sc disks, which has indeed been observed[14].

Whatever the true nature of the light-absorbing bodies, if they carry mass the implication is that the mass distribution in the disks will have a larger exponential scale length than that indicated by the observed light profile. In other words, the observed mass-to-luminosity ratio will increase with radius, despite the fact that the result implies an increase in true luminosities. This indicates a mass component that can produce flat rotation curves without the introduction of haloes of dark matter[15]. Successful fits of the rotation curve, with only disk material and obeying the extinction properties as presented here, have been made[16]. This result seriously weakens the evidence for dark haloes in Sb and Sc galaxies. Neither does it require alternative theories of gravity[17] to explain the flat rotation curves. This result does not effect the evidence for dark haloes in elliptical galaxies[18,19] (rotation velocities of which are, however, very difficult to explain with modification to Newton's law) or the missing-mass problem in spiral-poor clusters of galaxies, like the Coma cluster. ☐

Electronic properties of junctions between silicon and organic conducting polymers

DIODES formed from semiconductor/metal interfaces often display non-ideal electronic properties. For instance, silicon/metal (Schottky) diodes made from n-type silicon and a variety of contacting metals exhibit only small differences in their rectification properties, despite theoretical and practical expectations that changes in the metal should effect changes in device properties[1,2]. Similarly, Schottky diodes formed on p-type silicon generally exhibit ohmic behaviour with poor rectification characteristics. This lack of electrical response to changes in the properties of the contacting metal phase is generally attributed to interfacial reactions that take place during the high-temperature thermal or electron-beam deposition of metals onto silicon[3]. Here we describe the fabrication of diodes using a low-temperature chemical procedure, in which contact to the semiconductor is made by a layer of the conducting organic polymer, polyacetylene. Unlike conventional metals, the electrical properties of polyacetylene can be manipulated through choice of the polymer dopant. The resultant organic/inorganic interfaces behave more ideally than contacts with conventional metals, in that changes in the electrical properties of the conducting polymer exert a large and predictable effect on the electrical properties of the resulting semiconductor/polymer diodes.

Junctions were formed by preparing a layer of polyacetylene, $(CH)_x$, on Si (3.15 Ω cm (100) n-Si, or 2.45 Ω cm (111) p-Si, etched three times in 48% aqueous HF for 20 s, ref. 4) through the ring-opening metathesis polymerization of cyclooctatetraene[5]. Neat cyclooctatetraene was polymerized under nitrogen using the soluble tungsten carbene catalyst $W(CHC(CH_3)_3)(NR)(OR_F)_2$, where R is 2,6-$C_6H_3(CH(CH_3)_2)_2$ and OR_F is $OCCH_3(CF_3)_2$ (ref. 6). The catalyst (8 mg) was added to the liquid monomer (100 µl), and the desired substrate coated with the resulting solution. After 10 min, an ~300-µm-thick film of polymer formed on the Si surface. The excess monomer was removed under vacuum and the polyacetylene made conductive[7] either by exposure to iodine vapour followed by vacuum pumping, producing $(CHI_{0.17})_x$, or by exposure to a potassium benzophenone ketyl solution in 2-methyl tetrahydrofuran, producing $(CHK_{0.06})_x$. Conductivities of these doped films were determined by standard four-point-probe methods; for $(CHI_{0.17})_x$, $\sigma = 150\,\Omega^{-1}\,cm^{-1}$, and for $(CHK_{0.06})_x$, $\sigma = 50\,\Omega^{-1}\,cm^{-1}$. Electrical contact to the polyacetylene was made by immersing a gold wire in the cyclooctatetraene; the wire became encapsulated by the polymer during polymerization, and was held in place satisfactorily by the set polyacetylene film. Separate measurements determined that the doped polymers made low-resistance ($<50\,\Omega$) contacts to gold. The polyacetylene devices were always handled initially in a dry nitrogen atmosphere to avoid the decomposition reactions known to occur on exposure of doped and undoped polyacetylene to air[8]. When devices were to be handled in air, degradation was prevented by sealing the junctions with a coating of epoxy. Using these procedures, no degradation of electrical properties was noticed until at least two weeks after junction formation.

Previous work has shown that the rectification properties of n-Si and p-Si junctions with conventional metals are relatively insensitive to the contacting metal, even though such behaviour is not expected based on the ideal Schottky model of these junctions[1-3]. Figure 1 shows schematic energy diagrams for several types of Si junctions. In an ideal system, the position of the equilibrium Fermi level (E_F) in the Si is directly related to the work function of the contacting metal. The Si-band edge energies can be determined from the known values of the electron affinity of Si (4.05 V) and the Si band gap (1.12 eV)[2]. As can be seen in Fig. 1*b*, *c*, a change in the work function of the contacting phase should change the equilibrium position of the Si Fermi level. But for Si contacts to conventional metals, the Fermi level is found to be pinned to a small energy region. Metals ranging from copper to platinum (with work functions from 4.0 to 5.5 eV) all form low-barrier ohmic contacts to p-Si and rectifying junctions (with barrier heights of 0.7–0.9 eV) to n-Si, whatever the actual value of the metal work function (see Fig. 1*a*). High-barrier-height contacts to p-Si and low-barrier-height contacts to n-Si, as depicted in Fig. 1*c*, cannot be formed from direct Schottky contacts to these metals. Typical data for Si/Au junctions obtained in our laboratory are in agreement with these non-ideal properties (Fig. 2). The insensitivity of current density as a function of voltage (J–V properties) for a large variation in metal work function is termed Fermi-level pinning, and has generally been ascribed to the tendency of silicon to form metal silicides with most metals of interest[2,9-11]. The metal silicide layer then determines the J–V properties of the semiconductor/metal contacts, and precludes manipulation of the device properties by changing the metal.

Figure 2*a* displays the J–V properties of p-Si/$(CHI_{0.17})_x$ and p-Si/$(CHK_{0.06})_x$ contacts. A unique feature of a conducting polymer such as polyacetylene is that it can be doped with either oxidants or reductants, making it a material with a variable work function. The high-work-function[12] $(CHI_{0.17})_x$ overlayer yields a poorly rectifying contact to p-Si, as expected from the ideal band-equilibration model presented in Fig. 1*b*. Similarly, the low-work-function[13] $(CHK_{0.06})_x$ overlayer yields excellent rectifying properties on p-Si (Fig. 1*c*). A quantitative analysis can be made using the diode equation $J = J_0[\exp(qV/AkT) - 1]$, where k is the Boltzmann constant, T is the temperature, J_0 is the exchange (saturation) current density, A is the diode quality factor, and q is the electronic charge[2,3]. Better rectification corresponds to lower values of J_0 and ohmic contacts result from high J_0 values. The p-Si/$(CHK_{0.06})_x$ contact yielded a J_0 value of 6×10^{-7} A cm^{-2}, which is at least three orders of magnitude lower than the J_0 of conventional p-Si/metal contacts (typically 10^{-3} A cm^{-2}; see Fig. 2 and ref. 2). In contrast, the p-Si/$(CHI_{0.17})_x$ contact exhibited a J_0 value of 3×10^{-3} A cm^{-2}, providing a low-barrier contact.

The model in Fig. 1 also predicts that complementary behaviour should be observed with n-type Si as the semiconductor, where low-work-function contacts should yield ohmic contacts and high-work-function materials should provide rectifying diodes. Figure 2*b* displays the data for n-Si/$(CHI_{0.17})_x$ and n-Si/$(CHK_{0.06})_x$ contacts. The J_0 values for three separate n-Si/$(CHI_{0.17})_x$ samples were 2.9×10^{-8}, 2.7×10^{-8} and 2.4×10^{-8} A cm^{-2}, whereas the n-Si/$(CHK_{0.06})_x$ system had a poorly rectifying, ohmic J–V response, with a total resistance of 200 Ω. The range of J_0 values obtainable on conventional n-Si/metal interfaces is limited to about three orders of magnitude, whereas the J_0 values reported here span six orders of magnitude for the n-Si/$(CH)_x$ system (iodine and potassium dopants) and are in qualitative accord with the predictions of Fig. 1.

The behaviour of these conducting polymer/inorganic semiconductor interfaces is significant because it shows that restrictions on Schottky barrier devices can be overcome by using conducting organic polymer contact layers. Further, the ability to manipulate the properties of these interfaces by changing the polymer dopant allows switchable devices to be made. For instance, we have switched a device from rectifying to ohmic and back to rectifying behaviour by alternate iodine/alkali metal/iodine treatment of the $(CH)_x$ layer of an n-Si/$(CH)_x$ contact. A few previous studies of polyacetylene contacts to inorganic semiconductors have been reported using

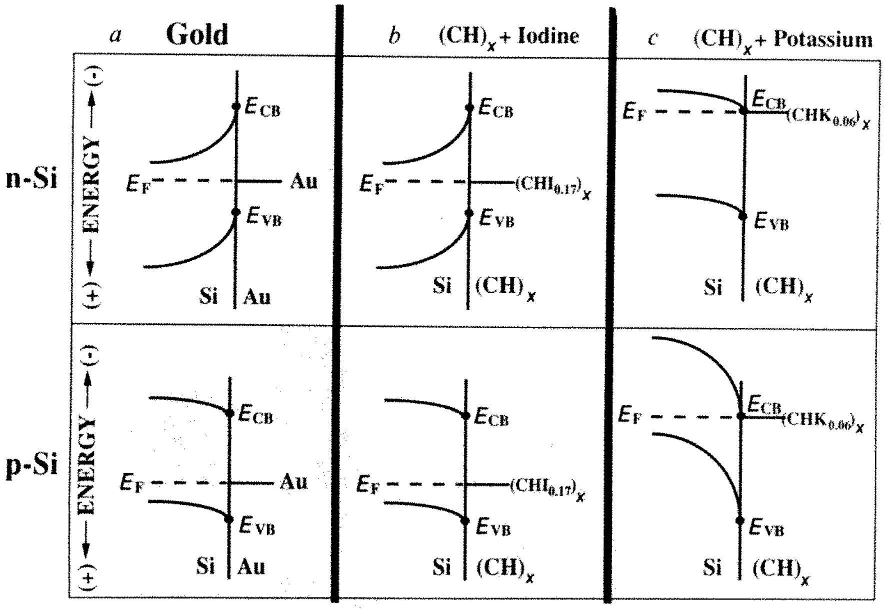

FIG. 1 Band-bending diagrams for n- and p-Si contacts to Au and $(CH)_x$ (I_2- and K-doped). The barrier height on n-Si is defined as the energy difference between the conduction-band edge, E_{CB}, of the Si and the equilibrium Fermi level, E_F of the contact. The barrier height for a p-type semiconductor is equal to $E_{VB} - E_F$. The energies of the conduction band (4.05 eV) and the valence band (5.17 eV) are obtained from experimental values of the electron affinity and band gap of Si. See text for discussion.

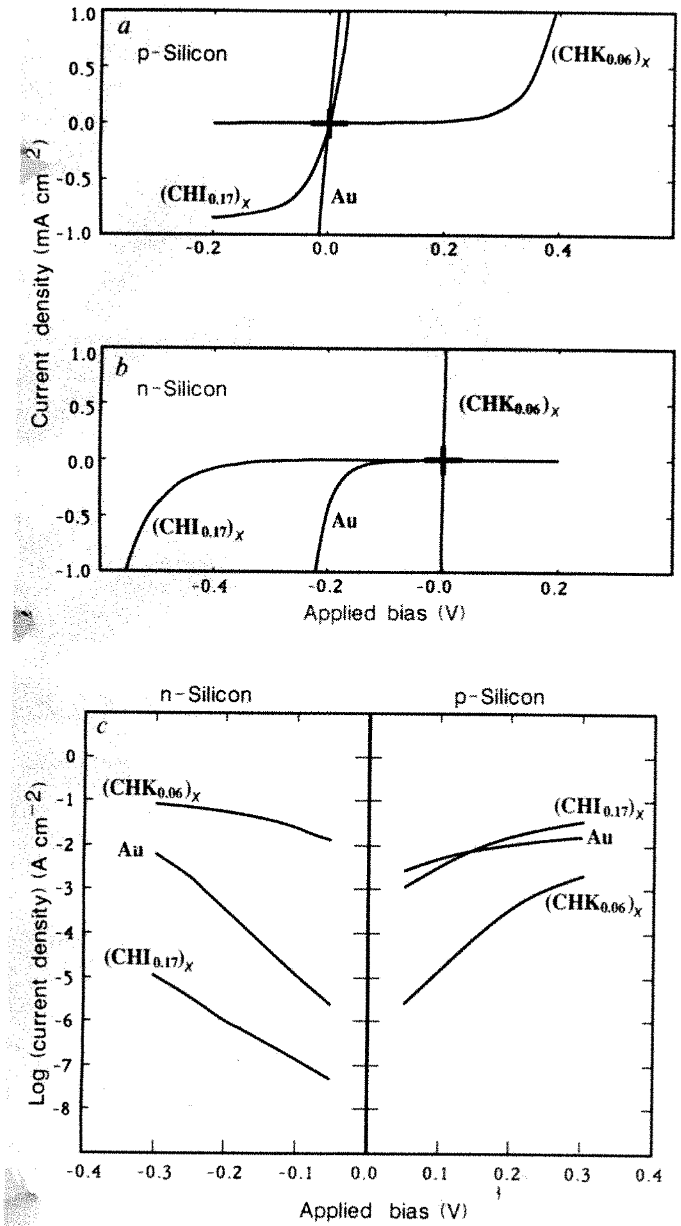

FIG. 2 Current density as a function of voltage for (*a*) p-type and (*b*) n-type Si/polyacetylene interfaces. The rectification characteristics change with the identity of the polymer dopant. The current-voltage curves for Si/Au diodes (typical of most Si/metal contacts) are added for comparison. The intercept (at zero applied bias) of the plot of log (current density) against forward bias (*c*) is a measure of the exchange (saturation) current density (J_0) for each interface. Curvature in the log plots at higher current densities arises from series-resistance effects in the diodes. The ratios of forward to reverse rectification (at ±1 V) are: p-Si/$(\mathrm{CHK}_{0.06})_x = 6\times10^3$, p-Si/$(\mathrm{CHI}_{0.17})_x = 2\times10^2$, n-Si/$(\mathrm{CHI}_{0.17})_x = 5\times10^4$. The diode quality factors are: n-Si/$(\mathrm{CHI}_{0.17})_x = 1.8$, p-Si/$(\mathrm{CHK}_{0.06})_x = 1.2$.

polyacetylene prepared by the Shirakawa route[14-16], although the ability to manipulate the device properties by varying the polymer dopant was not described. The Shirakawa polyacetylene has been used in photoelectrochemical cells to inhibit photocorrosion and to mediate charge transport between the semiconductor and a solution redox species[17], but the electrical properties of the isolated semiconductor/conducting polymer junction were not reported. New synthetic routes to polyacetylene have resulted in materials with superior processing and electronic characteristics. For instance, the recent fabrication by Burroughes *et al.*[18] of transistors and metal-insulator-semiconductor capacitors using polyacetylene as the active element relied on the Feast precursor method to generate homogeneous defect-free polyacetylene films[19,20]. Our work uses the recently developed liquid-phase ring-opening metathesis method of polymerizing cyclooctatetraene, which is more controllable than the gas-phase polymerization of acetylene[5]. This allows for uniform coverage of material over the semiconductor surface and for facile control of the morphology of the layer of doped organic polymer. The ability to prepare junctions with well defined electrical properties is a key step towards the development of polymer-based electronic devices. □

Coherent structures at the ocean surface in convectively unstable conditions

Alexander V. Soloviev

P. P. Shirshov Institute of Oceanology USSR Academy of Sciences,
23 Krasicova, Moscow 117218, USSR

THE turbulent boundary layer at the ocean surface has some dynamical similarities to the atmospheric boundary layer[1-4]. The atmospheric turbulent boundary layer may exhibit not only random fluctuations but also spatially coherent, organized motion[5,6]. Thorpe[1] conjectured that such organized motion should also be found in the upper ocean boundary layer in convectively unstable conditions. Here I report on observations made in the tropical Atlantic Ocean which confirm this view. Horizontal temperature profiles obtained at a depth of 2 m at night revealed ramp-like structures. Vertical velocity profiles in the upper few metres of the ocean was determined using a free-rising profiler, and exhibited abrupt changes corresponding to sudden changes in temperature. These features are known[5,6] to be characteristic of spatially coherent, organized motions in turbulent boundary layers.

Laboratory experiments[7] in a coordinate system moving with the average convection velocity of coherent structures show that the typical organized motion in the unstratified turbulent boundary layer resembles an inclined three-dimensional horseshoe vortex. In stratified conditions the vorticity features are accompanied by density ones. Measurements[6] using a fixed probe in

U_0 is the speed of probe relative to water, θ_0 the angle of ship's motion with respect to wind; V_{10} is the wind speed at a height of 10 m; T_w, T_s and H_w, H_s are the periods and the heights of wind waves and swell, respectively; Q_R is the solar insolation, Q_n the heat loss from the ocean surface owing to latent, sensible and long-wave radiative heat fluxes; $u_*=(\tau/\rho)^{1/2}$ is the friction velocity, where τ is the wind stress and ρ is the density of water; $T_*=Q_0/xu_*c_p\rho)$ is the friction temperature, where Q_0 is the heat flux in the upper layer of the ocean defined as $Q_0=Q_n+(1-A)(1-f(z_0))Q_R$, $A=0.05$ is the albedo of the ocean surface, f is a function describing volume absorption of solar radiation in the upper layer of the ocean, $z_0=2$ m, $x=0.4$ is von Karman's constant and c_p is the specific heat; $L_*=u_*^3/(x\gamma gQ_0/c_p\rho)$ is the Monin–Oboukhov length scale, where γ is the coefficient of thermal expansion of water and g is the acceleration due to gravity. Friction velocity was calculated as: $u_*=(\rho_a/\rho)^{1/2}C_{10}^{1/2}V_{10}$ where ρ_a is the density of air and C_{10} is the drag coefficient calculated in ref. 15, 1.04×10^{-3}. The latent and sensible heat fluxes were calculated from the air–ocean observations using standard bulk formulation[16]. Radiation fluxes were measured directly. Volume absorption of solar radiation was calculated as in ref. 17. Parameters of surface waves were obtained visually by a meteorologist.

* wind direction was unstable.

the convectively unstable atmospheric boundary layer show that the temperature has a characteristic ramp profile—a gradual rise followed by a relatively sharp decrease downstream—which leads to a skewed temperature derivative[1]. The sharp change of temperature occurs when a frontal interface of the horseshoe vortex passes the temperature probe. The temperature ramps in the atmospheric boundary layer were suggested[5] to be a signature of organized large-scale motion. In the surface ocean only the coherent structures of day-time stably stratified conditions have so far been observed[1,8].

An underwater probe[9] was mounted on the bow of the RV *Akademic Kurchatov* at a depth of 2 m (Fig. 1). The probe measured the temperature and conductivity fluctuations ahead of the moving vessel. The uncertainty on the temperature measurement was ~±0.001 °C; the response time was 0.1 s. An acceleration sensor registered vertical motions of the probe caused by the pitching of the vessel. The acceleration signal was doubly integrated and processed by a digital high-pass cosine filter with a 0.02-Hz cut-off frequency (to avoid low-frequency trends) and therefore gives information about the depth variation of the probe with respect to a mean hydrostatic level of the ocean.

At the probe mount the radius of curvative of the vessel's hull is ~10 cm, with a frontal angle of 16° (Fig. 1). In front of a moving sphere the streamlines are not appreciably disturbed at the distances greater than ~3 radii[10]. Owing to a 'knife-edge' hull, the *Akademic Kurchatov* produces practically no bow wave ahead of itself, as confirmed by photographs. No turbulent or wave perturbations from the vessel's body are therefore expected in the measurement zone.

A free-rising profiler[4] (Fig. 1) measured vertical profiles of conductivity and the vertical component of velocity fluctuations in the frequency range 2–250 Hz. The vertical velocity of the profiler was 2.2 m s^{-1}. Temperature profiles were calculated from the conductivity profiles neglecting salinity variation[4,11]. The uncertainties on the temperature and velocity fluctuations were ~0.001 °C and 1 mm s^{-1} respectively. The profiler tends to follow the wave-induced orbital motion in the long surface waves[4]. This reduces the influence of surface waves on turbulence measurements in the upper boundary layer of the ocean; the vertical profiles may be found relative to a moving coordinate system following long waves (details are given in ref. 4).

Measurements with the underwater probe were made at 37° W between 1° N and 20° N in June 1985. At several points along this section the measurements were also made into the wind direction. Here I ignore data obtained when it was raining or in regions of oceanic fronts.

At night the temperature fluctuations in the upper ocean appreciably exceeded the noise level of the probe only at wind speeds ≲5–7 m s^{-1}. In particular the measurements made in the

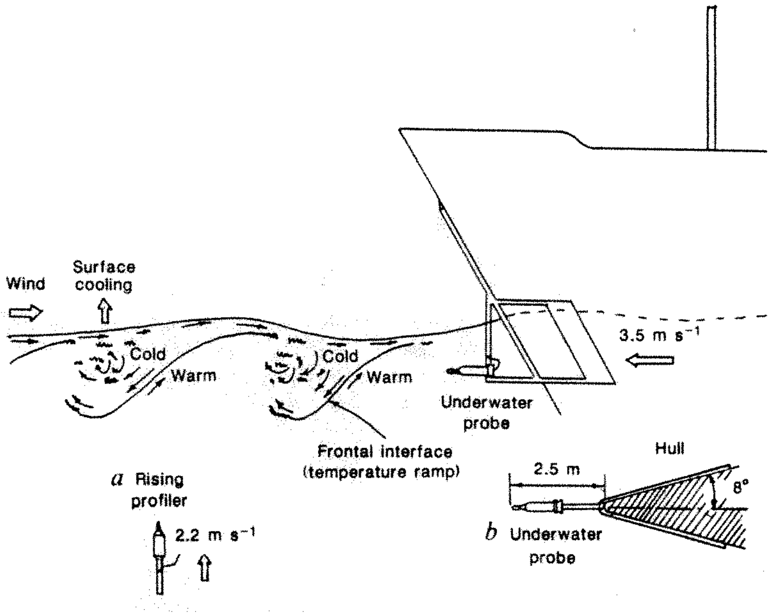

FIG. 1 Schematic representation showing spatially coherent organized motion in the upper ocean boundary layer and experimental techniques and devices used in measurements. *a*, Free-rising profiler, *b*, Top view at the probe mount (2 m below).

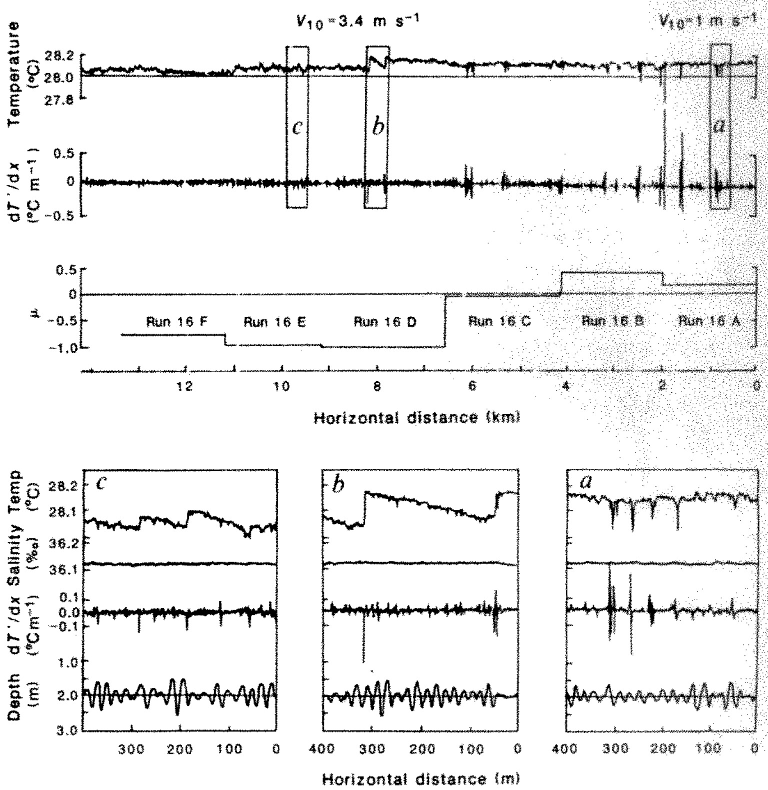

FIG. 2 Top, records of temperature (T), fluctuation-temperature derivative (dT'/dx) and skewness (μ_3) of the derivative obtained at 2 m depth in the early morning of 21 June (run 16 in Table 1). The graphs are plotted from right to left. Below, the marked regions (a, b and c) from above are shown in more detail along with the appropriate salinity records and depth variations of the probe relative to the mean hydrostatic level of the ocean, calculated from the accelerometer signal.

night of 20/21 June met this requirement (runs 16 and 17 in Table 1). Run 16 shown in Fig. 2 was made with the vessel heading into the wind at a speed of 3.5 m s^{-1}, after diurnal thermocline deepening. The real thickness of the seasonal mixed layer was ~50 m. The initial part of the record (run 16 A, B) obtained in almost calm weather conditions was typical of buoyancy-driven convection ($z_0/L_* \approx -40$, where z_0 is the mean depth of the probe, L_* is the Monin-Oboukhov scale), isolated narrow regions of cooler water of ~1-m scale (Fig. 2a) being ascribed to intersection of so called 'thermals' previously observed on the vertical temperature profiles in the convectively unstable upper boundary layer of the ocean[11,12] and of a lake[13]. A ramp-like structure with negative skewness μ_3 of the temperature derivative appeared in the temperature record (run 16, D-F in Fig. 2) after the wind speed increased. The value of $z_0/L_* \approx -1.3$ indicated that in this case the shear could have an important role.

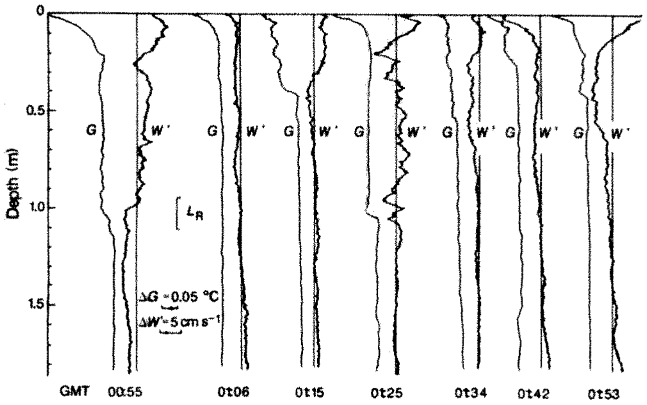

FIG. 3 Vertical profiles of temperature (G, calculated from conductivity profiles assuming constant salinity) and vertical component of velocity fluctuation (W') in the upper ocean in convectively unstable conditions. A positive $\Delta W'$ indicates a positive velocity change of the flow along the profiler. The vertical length scale (L_R) represents the relaxation time of velocity sensor, calculated using $L_R = W_0/(2\pi f_1) = 17.5$ cm, where $W_0 = 220$ cm s^{-1} is vertical velocity of profiler, $f_1 = 2$ Hz is lower frequency limit of the sensor.

Patterned on Fig. 4 of ref. 8, which shows processes of the vertical transport in a stably stratified shear boundary layer of the upper ocean, Fig. 1 reconstructs water circulation in unstably stratified conditions. As the ship moves upwind the ramps are observed as the probe passes from the 'warm water' to the 'cold water' side of the inclined sharp interfaces (Fig. 1). The ramps on the temperature record shown in Fig. 2 (run 16, D-F) are also consistent with this sketch.

The skewness of the temperature derivative for run 16 D-F falls in the range −0.7 to −1.0. In the convectively unstable atmospheric boundary layer the skewness in the presence of the coherent structure is near the latter value[14]. As expected, the mean value of μ_3 measured in the night-time convectively unstable conditions depended on the direction of the ship's motion relative to the wind (compare run 16, D-F with run 17, A-C in Table 1). During the day the μ_3 became positive (see runs 13 and 14), the values being near those obtained previously[1,8] in day-time stably stratified upper ocean in similar wind conditions and towing angles.

The vertical velocities measured by the free-rising profiler complement the ship-borne observations. This instrument was deployed 91 times in wind speeds of 2-7.5 m s^{-1} in the vicinity of 20° N, 37° W. Thirteen measurements (7 on 16 May and 6 on 23 May) were made under weather conditions very similar to those during the runs on 20-21 June (see Table 1). Figure 3 shows a series of seven successive measurements of temperature and vertical velocity fluctuations made by the free-rising profiler in the early morning of 16 May. The time interval between successive measurements was ~10 min and the vessel wind drift during this period was several tens of metres. The investigated coherent structure had time and spatial scales of the same order, and therefore no determinable connection between any of the series profiles is expected.

The abrupt change of temperature and vertical velocity component at the depth of 1.08 m observed on the profiles obtained at 01:25 GMT (Fig. 3) can be ascribed to vertical intersection of a frontal interface (see the sketch on Fig. 1 showing eddies and frontal interfaces in the upper ocean boundary layer). The temperature change at this interface was $\Delta\theta \approx -0.05$ °C, the appropriate change of the vertical velocity being $\Delta W \approx 2.5 \text{ cm s}^{-1}$. The sign of the vertical velocity change at 1.08 m depth indicated that the cold water was moving along the interface away from the ocean surface. This coincides with water circulation induced by the large-scale eddies in the upper ocean boundary layer (Fig. 1).

Similar profiles obtained at 00:55 GMT (Fig. 3), but having the opposite sign of the vertical velocity change at 0.95 m depth and the same sign of the temperature change as the profiles discussed above, may be interpreted as a result of intersection of the region where the cold water was moving along the frontal interface toward the ocean surface (see Fig. 1).

The profiles obtained at 01:06 GMT have no substantial changes either in temperature or in vertical component of velocity. These profiles can be interpreted as referring to a space between the large-scale eddies. The other four pairs of profiles shown in Fig. 3 apparently are concerned with cases when the profiler passes through less pronounced regions of the organized vortex structure. Vertical profiles obtained on 23 May had similar temperature and velocity features. □

Consumption of atmospheric methane by tundra soils

S. C. Whalen & W. S. Reeburgh

Institute of Marine Science, University of Alaska, Fairbanks,
Alaska 99775-1080, USA

EMISSION of methane from tundra soil contributes about 10% of the global atmospheric methane budget[1]. Moreover, tundra soils contain 15% of global soil carbon[2], so the response of this large carbon reservoir to projected global warming[3,4] could be important. Coupled biological models[3–6] predict that a warmer climate will increase methane emission through increased rates of methanogenesis. Microbial oxidation of methane is, however, a possible control on emissions that has previously been overlooked. Here we report the results of field and laboratory experiments on methane consumption by tundra soils. For methane concentrations ranging from below to well above ambient, moist soils were found to consume methane rapidly; in non-waterlogged soils, equilibration with atmospheric methane was fast relative to microbial oxidation. We conclude that lowering of the water table in tundra as a result of a warmer, drier climate will decrease methane fluxes and could cause these areas to provide a negative feedback for atmospheric methane.

Methane is one of several radiatively active trace gases undergoing an atmospheric concentration increase of 1% yr^{-1} or more[7,8], and has the potential to cause climate change through atmospheric warming[9–11]. Global methane budgets balance net CH_4 sources to the atmosphere against the atmospheric photochemical sink, using ^{14}C and ^{13}C contents, and isotope fractionation factors as constraints[1,12] on the source terms. Other methane sinks (consumption by soils and marine sediments) are incorporated in the net source terms and are not explicitly identified in these budgets. Some climate models incorporating greenhouse gas increases predict higher temperatures and drier summer conditions for high northern latitudes[13–15]. Coupled biological models predict increased CH_4 emission as a result of increased rates of methanogenesis[3–6], but CH_4 oxidation was neglected in these models. Net consumption of atmospheric CH_4 has been reported in some soils of temperature forests[16–18] and swamps[19], tropical forests[18,20–22], savannah[23] and tundra[24,25]. The areal extent of the soil CH_4 sink is poorly understood, but it is estimated to account for <1–58 Tg yr^{-1}, or up to 11% of the global photochemical sink[16,17,21].

Our observations were made in a moist tundra meadow on Unalaska Island, Aleutian Islands, adjacent to Skan Bay (53° N, 167° W). Plant cover was a continuous mat of mosses invaded by lichens, cottongrasses (*Eriophorum* sp.), low-lying ferns and dwarf shrubs (*Vaccinium* sp). The air temperature ranged between 5 and 8 °C; the soil temperature was 7 °C and uniform in the upper 15 cm.

We collected syringe samples of gas from three static chambers at 0.25-h intervals and analysed them by gas chromatography[26] on board the RV *Alpha Helix*. The chambers were fitted with a capillary bleed to equalize pressure following sampling. Chamber measurements yield net fluxes—in the measurements reported here, the methane concentration decreased with time, indicating that consumption exceeded production in the moist

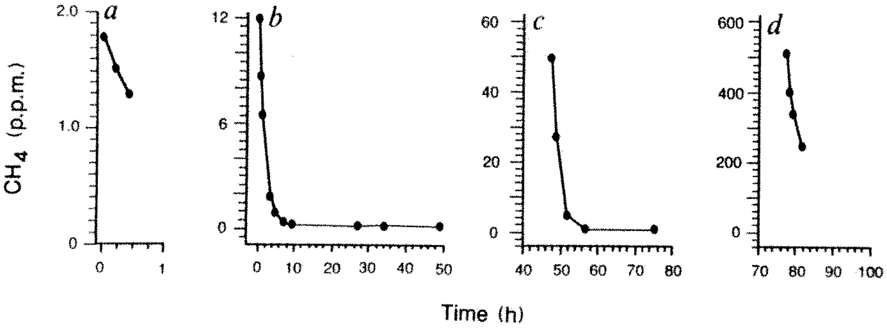

FIG. 1 Consumption of headspace methane in a field experiment using a static chamber. *a*, consumption of atmospheric CH_4 to sub-ambient levels on 8 October 1987. *b–d*, Results of subsequent experiments (9–12 October 1987) in which the headspace of the same chamber was adjusted to initial CH_4 concentrations of 10, 50 and 550 p.p.m., respectively. Chamber temperatures differed from ambient temperatures by <2 °C during the experiment.

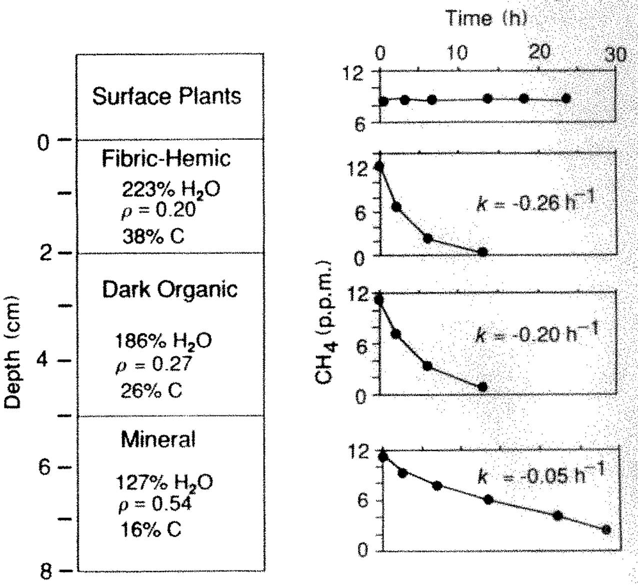

FIG. 2 Soil characteristics and depth distribution of CH_4 consumption in a soil core. Maximum consumption rates occur in the top 5 cm of the core. No CH_4 was consumed by the vegetation. Water content ([wet weight/dry weight] − 1), organic content ([loss on ignition]/[dry weight]) and bulk density (ρ represents [oven-dried mass]/[field volume] in g cm^{-3}) are given for each of the soil units.

soils studied. In all cases, the concentrations eventually level off to a small but non-zero value. Figure 1 shows the results of an experiment on one of two chambers where atmospheric methane (~1.7 p.p.m.) was consumed, and subsequent experiments where the chamber headspace was adjusted to initial CH_4 concentrations of 10, 50 and 500 p.p.m. by injection of millilitre quantities of a 95% Ar:5% CH_4 mixture. Headspace concentrations in chambers with 10 p.p.m. CH_4 became sub-ambient in 4-7 h and decreased to 0.14 p.p.m. in as little as 8 h.

Soil cores from the same site were collected in plastic tubes (6.7-cm inner diameter, 2-mm wall) for laboratory studies of CH_4 oxidation and the depth distribution of CH_4 oxidizing potential. We avoided sample disturbance by cutting around the tube perimeters with a serrated knife as the tubes were inserted. The cores collected were 2-12 cm long, and showed a 2-cm fibric-hemic layer below the surface vegetation followed by a 3-cm dark organic-rich layer that graded into a weathered mineral horizon extending below the sample (Fig. 2). These cores were capped at the base and were placed in ~1-l Mason jars, the lids of which were equipped with valves and a septum. The jar headspaces were maintained at constant pressure by introducing ambient air following sample removal; this headspace dilution was negligible. Because only the soil surface was in contact with the jar atmosphere, the cores in jars were physically equivalent to the field chambers. The ratios of headspace volume to soil surface area for the chambers and jars agreed to within 5%, so CH_4 uptake kinetics for both are comparable. The response of whole cores to CH_4 additions at ambient air temperatures was repeatable and identical to the field chambers—the first-order rate constants for methane consumption in both were ~−0.25 h^{-1} and headspace methane concentrations as low as 0.7 p.p.m. were observed in 6-13 h.

Methane consumption by core segments representing the various soil horizons was measured in jar experiments using initial headspace CH_4 concentrations of ~10 p.p.m. Microlitre quantities of the same Ar:CH_4 mixture that was used in the chamber experiments were added to the jars. The results are shown in Fig. 2. The surface vegetation consumed no CH_4. Methane was consumed by all soil layers, with the highest rates in the 0-2 cm and 2-5 cm layers. A portion of each core segment was autoclaved; these samples consumed no CH_4 in 24 h, indicating that CH_4 consumption is biologically mediated.

We performed a tracer experiment to determine the products of methane oxidation and their distribution in soils. Two cores with nearly identical methane uptake kinetics (cores C and E) were used in this experiment, one to follow CH_4 decreases and the other to follow changes in headspace $^{14}CH_4$ and $^{14}CO_2$. The experiment was conducted in the dark to prevent photosynthetic uptake of $^{14}CO_2$. The headspaces of the jars containing both cores were adjusted to an initial CH_4 concentration of ~10 p.p.m., but stable CH_4 was added to core C whereas core E received CH_4 containing $^{14}CH_4$ (2.8×10^8 d.p.m. cm^{-3}; d.p.m., disintegrations per minute). Core E was sampled at time intervals based on decreases in the stable CH_4 concentration of core C. Headspace samples (10 cm^3) were injected into a metal and glass stripping/oxidation line[27] and were carried in a helium flow through bubbler traps and a quartz combustion tube filled with CuO heated to 800 °C. The $^{14}CO_2$ was trapped in 1N NaOH before combustion and the $^{14}CH_4$ was trapped in Woeller's solution[28] as $^{14}CO_2$ following combustion. The jar headspaces were maintained at constant pressure by introducing ambient air following sample removal. The results are corrected for dilution (1.6% per sample). The experiment was terminated after 11 h when the CH_4 concentration reached 0.4 p.p.m. and 95% of the added $^{14}CH_4$ had been consumed. The remaining headspace $^{14}CH_4$ and $^{14}CO_2$ was recovered with a series of helium flushes; the jar and core were frozen and the ^{14}C incorporated in the core was assayed by dry combustion of freeze-dried homogenized samples of core segments.

Figure 3 shows the results of the tracer experiment. Core C showed a decrease in headspace CH_4 that parallels the $^{14}CH_4$ decrease in core E. The headspace $^{14}CO_2$ activity indicated that part of the consumed $^{14}CH_4$ was retained by the core. We accounted for 96% of the $^{14}CH_4$ added to core E; 46% of this was respired as $^{14}CO_2$ and 54% was recovered by dry combustion. The fraction recovered by dry combustion represents $^{14}CH_4$ assimilated into microbial biomass, organic matter and inorganic matter. We made no attempt to independently assay the inorganic fraction; these soils are carbonate-free and soil pH values of 5.7 suggest that this fraction is small.

Interpretation of experiments involving amended atmosphere requires an understanding of the timescale of equilibration between the soil and headspace for added gases. The equilibration time was evaluated for core E with a relaxation technique[29] that involved inhibiting methane oxidation and following equilibration of added CH_4. Acetylene, a well-known inhibitor of CH_4 oxidation[30], was added to the headspace (30 p.p.m. final concentration) before sectioning core E for freeze-drying and dry combustion. Methane was then added and headspace concentrations were measured at 1-min intervals until the changes could not be resolved (6 min). This approach shows that equilibration is a two-step process: a fast ($k = -1.54$ min^{-1})

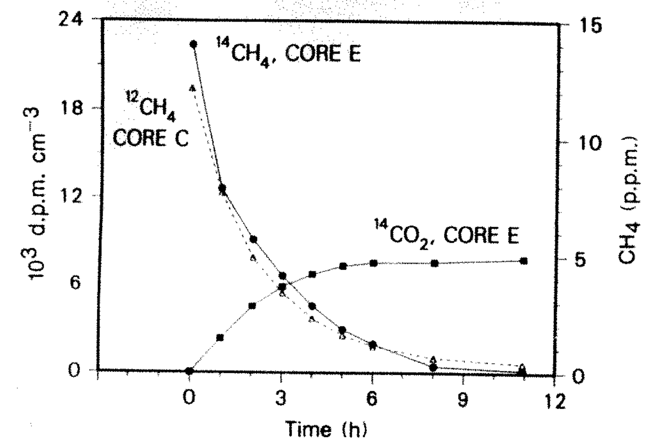

FIG. 3 $^{14}CH_4$ oxidation as a function of time. This jar experiment was conducted on 12 October 1987, using two cores with almost identical CH_4 oxidizing characteristics. The headspace of core C was amended with CH_4 and was used to guide sampling core E, which was amended with $^{14}CH_4$.

process, presumably involving the porous surface material or large voids, followed by a slower ($k = -0.75\ \text{min}^{-1}$) process involving more compact material or adjacent smaller voids. These first-order equilibration or relaxation constants show that equilibration is much faster than biological consumption ($k = -0.004\ \text{min}^{-1}$). Thus, CH_4 consumption is not controlled by transport in tundra soils. The initial samples in the chamber, jar and tracer experiments (taken 15 min after adjusting initial concentrations in the chamber and jar experiments; 5 min after tracer addition) contain no bias owing to incomplete equilibration.

The ability of these soils to respond to methane increases without a lag and to consume a wide (thousand-fold) range of concentrations with no indication of saturation (all follow first-order consumption kinetics) indicates that they could be an important sink. These methane consumption measurements were made at the low end (7 °C) of the reported temperature range (2–30 °C). Methane consumption rates of 2.7 mg m^{-2} d^{-1} for our unamended chambers lie in the middle of reported ranges (0.2–4.2 mg m^{-2} d^{-1})[16-25], indicating that methane oxidation can be important in cold soils. Final methane concentrations as low as those observed in our chamber and jar experiments (0.1–0.4 p.p.m.) have not been reported in previous chamber experiments, but similar concentrations have been observed in soils[16]. Static chambers are rarely allowed to 'run down', so the high final concentrations in previous studies can be expected when static chambers are used for only short periods to avoid disturbing sub-surface gradients[31]. Our results demonstrate that soil oxidation of atmospheric CH_4 is microbially mediated and point to a population capable of oxidizing CH_4 at concentrations ten times lower than ambient atmospheric concentrations. Kinetic properties of cultured methanotrophs are not consistent with growth using atmospheric CH_4 as the sole carbon source, implying a threshold for growth well above atmospheric levels[32]. Mixotrophic growth, co-oxidation by non-methanotrophs such as ammonium-oxidizing bacteria, or induction of high-methane-affinity enzyme systems are processes that may be important in maintaining these low CH_4 concentrations[30,32,33].

These measurements have implications important to tundra systems under the projected warmer drier conditions. The subsurface CH_4 oxidizing activity is important in controlling upward CH_4 fluxes at sites where vascular plants are absent. Vascular plants transport CH_4 and effectively bypass the CH_4 oxidizing zone. Tussock and low-shrub tundra (35–50% vascular plant cover) are expected to show larger consumption effects than wet meadow tundra (80–90% vascular plant cover)[26]. Our previous observations at relatively wet permanent sites have not shown net oxidation[26]. Methane fluxes from tundra[34] and swamp[19] sites, however, are positively correlated with the level of the water table, and the 20% of the stations occupied during a high-latitude transect study[24], all with a lowered water table, had zero or negative CH_4 fluxes.

Consumption of atmospheric CH_4 by soils depends on transport to zones of consuming activity. Transport in waterlogged tundra soils is by aqueous molecular diffusion. Waterlogged tundra sites have a methane consumption maximum centred near the water table (the oxic/anoxic boundary), sustained by upward diffusion of dissolved CH_4. By contrast, transport in dry tundra soils is by gas-phase diffusion (10^5 times faster than aqueous), so porous low-resistance tundra soils do not limit the supply of methane. Expected consequences of atmospheric warming (such as a lowered water table, increased seasonal thaw depth, or permafrost melting) will increase the vertical extent of oxidized tundra soil and enhance oxidation of CH_4. Our measurements demonstrate that the oxidation of atmospheric CH_4 occurs in oxic soils and is not limited by diffusion in non-waterlogged soils, so a negative feedback on atmospheric CH_4 concentration is possible. Furthermore, the CO_2 produced by oxidizing CH_4 is 20 times less effective as a greenhouse gas[8]. □

Uranium and ^{10}Be enrichments by fluids in Andean arc magmas

VOLCANIC rocks from subduction settings frequently contain ^{10}Be enrichments that have been attributed to sediment subduction[1-6], and are often characterized by (^{238}U/^{230}Th) ratios greater than unity, in contrast to mid-ocean-ridge and ocean-island basalts[7,8]. Here we report such an excess of ^{238}U over ^{230}Th in historic lavas from the Southern Volcanic Zone of Chile (33–42° S). The greatest uranium excess is found south of 39° S, where ^{10}Be/^{9}Be ratios are highest and the trench is filled with sediment. These features suggest that both U and ^{10}Be enrichments result from preferential partitioning of U and Be into a fluid phase during dehydration of the recently subducted sediments. The presence of strong ^{238}U–^{230}Th disequilibria in basaltic magmas of the Southern Volcanic Zone suggests that the timescale for dehydration, melting and eruption in this arc is probably less than ~20,000 yr.

Andean Southern Volcanic Zone (SVZ), where subduction-related volcanism has occurred continuously since the Jurassic, is a single arc segment underlain by continental crust (Fig. 1). North of 37° S, the crust ranges in age from late Palaeozoic to Triassic and its thickness increases sharply from 35 km to 55–60 km between 34 and 36° S (ref. 9). South of 37° S, the crust is of Mesozoic to Cenozoic age and has a relatively uniform thickness of 30-35 km until 40° S where it thickens slightly to ~40 km (ref. 10). Throughout the SVZ the geometry and rate of subduction and the distance of the volcanic front from the trench remain nearly constant, although in the northern part between 33-37° S the age of the subducting crust is ~40 Myr and the trench is sediment-poor, whereas in the southern part between 37 and 42° S the age of the subducting crust is ~18 Myr and the trench is filled with sediment[11]. The absence of a significant accretionary prism inboard of the trench indicates that sediments are subducted beneath the arc[12].

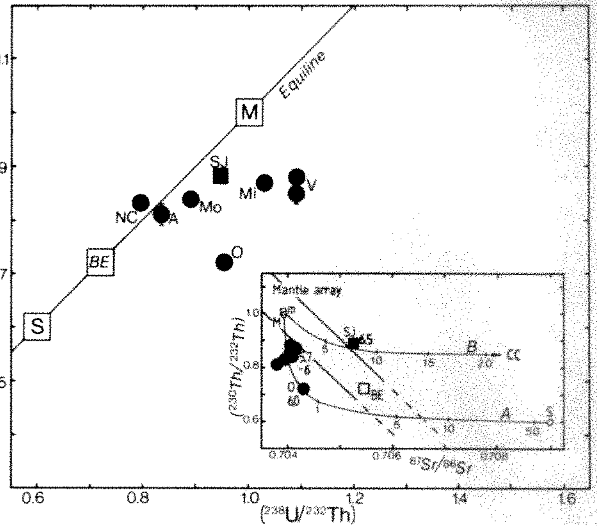

FIG. 2 Data for the SVZ volcanoes in the (^{230}Th/^{232}Th)–(^{238}U/^{232}Th) isochron diagram. Samples in U–Th radioactive equilibrium would plot on the equiline. NC, Nevados de Chillan; A, Antuco; Mo, Mocho; SJ, San Jose; O, Osorno; Mi, Mirador; V, Villarrica. BE is the 'Bulk Earth' value[18]; M, mantle of ocean-island-basalt (OIB) type; S, sedimentary component. The SVZ mantle source on the equiline can have been modified by addition of ancient sediments to an OIB-like mantle. Inset, Th–Sr isotope diagram of the same samples. The numbers adjacent to data points indicate the δ^{18}O values of the samples. Curve A: Hypothetical model explaining the modification of the mantle sources under the SVZ by mixing between an OIB-like mantle source (M), with (^{230}Th/^{232}Th)=1.0, ^{87}Sr/^{86}Sr=0.7039, Th=0.04 p.p.m., Sr=20 p.p.m., and a sedimentary component (S) with (^{230}Th/^{232}Th)=0.6 (inferred from Th/U ratio), ^{87}Sr/^{86}Sr=0.709, Th=15 p.p.m., and Sr=300 p.p.m. (from ref. 19). Curve B: Crustal contamination model for the San Jose magma: A mantle melt (m), having (^{230}Th/^{232}Th)=1.0, ^{87}Sr/^{86}Sr=0.7039, Th=0.5 p.p.m., Sr=400 p.p.m., assimilates Palaeozoic–Triassic crustal rocks (CC) with (^{230}Th/^{232}Th)=0.8, ^{87}Sr/^{86}Sr=0.770, Th=10 p.p.m., and Sr=100 p.p.m. (from ref. 9). The numbers on curves A and B refer to the percentage of contamination by sediments and continental crust, respectively.

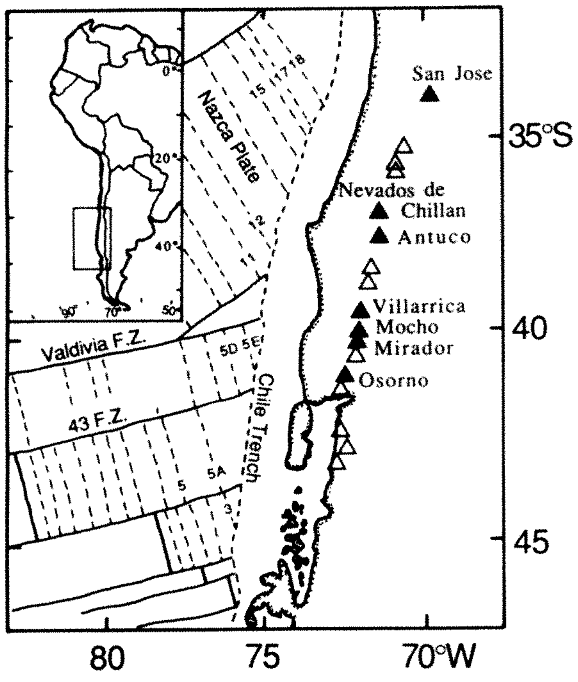

FIG. 1 Map of a part of the Southern Volcanic Zone of the Andes showing the volcanoes discussed. Nazca plate features are taken from ref. 11.

Our samples are lavas from eight historic eruptions at seven volcanic centres between 33 and 42° S (Fig. 1). The samples are calc-alkaline, high Al basalts and basaltic andesites, with two andesites and a dacite included in the suite. Only one volcano, San Jose is situated to the north of 37° S and, therefore, has been constructed on a thicker and older crust than the other volcanoes. For the six volcanic centres south of 37° S, medium-K lavas consist of anhydrous mineral assemblages composed predominantly of olivine and plagioclase, with occasional clinopyroxene in mafic rocks, and plagioclase and two pyroxenes in intermediate lavas, whereas the lava from San Jose is a high-K hornblende andesite. The analytical results of ^{238}U–^{230}Th disequilibria and Sr and O isotopes together with previous ^{10}Be measurements[2] are reported in Table 1.

When plotted on the isochron diagram (Fig. 2) the SVZ data form a nearly horizontal array extending right from the equiline. The (^{238}U/^{230}Th) ratios range from 0.96 to 1.33, whereas (^{230}Th/^{232}Th) ratios vary only between 0.81 to 0.88, with the exception of the Osorno basalt, which has the lowest measured (^{230}Th/^{232}Th) ratio of 0.72. Intermediate and evolved lavas are similar to mafic ones in terms of (^{230}Th/^{232}Th) ratios. Despite

U and Th contents are determined by isotope-dilution mass spectrometry. Ratios in parenthesis are activity ratios. The relative 1σ errors on ($^{238}U/^{232}Th$) and ($^{238}U/^{230}Th$) ratios are estimated at 0.59 and 2% respectively. The errors on ($^{230}Th/^{232}Th$) are 1σ statistical α-counting errors. Reproducibilities (1σ) for measurements are better than ±20% for $^{10}Be/^9Be$ ratio. The Sr isotope ratios have bee normalized to a value of $^{86}Sr/^{88}Sr = 0.1194$ and $^{87}Sr/^{86}Sr = 0.71022$ for the NBS-987 standard; the errors are 2σ in-run errors. Reproducibilities for $\delta^{18}O$ are better than 0.2‰ and the NBS-28 gav $\delta^{18}O = 9.6‰$ ($\delta^{18}O = [(^{18}O/^{16}O)_{sample}/(^{18}O/^{16}O)_{SMOW}] - 1$, SMOW is standard mean ocean water). wt%, weight per cent.

the near constancy of Th isotope ratios, the Th/U ratios vary considerably (2.77-3.82) but with no clear geographical trend along the strike of the arc.

The ($^{230}Th/^{232}Th$) ratios of SVZ lavas are too low to be inherited from a mantle source such as those giving rise to mid-ocean-ridge basalt (MORB) or ocean island basalt (OIB), yet the similarity of the ($^{230}Th/^{232}Th$) ratios of most SVZ lavas favours an origin from a rather homogeneous reservoir. Crustal contamination would hardly result in the constant ($^{230}Th/^{232}Th$) ratios in different lava types from distant volcanoes. The low Th isotope ratios also preclude any major involvement of altered basalts from the subducted oceanic crust. Such basalts would be enriched in uranium and therefore would have high ($^{230}Th/^{232}Th$) ratios after radioactive equilibrium had been reached. The low ($^{230}Th/^{232}Th$) may be a characteristic of a subduction-modified mantle wedge underlying most part of the studied area. As sediments have been subducted since the Jurassic, the mantle sources have probably been affected by mixing with this component. Pelagic and terrigenous sediments often have high Th/U, and hence low ($^{230}Th/^{232}Th$) ratios (see Fig. 2). Thus sediment injection may have lowered the ($^{230}Th/^{232}Th$) of the sub-arc mantle, and this can explain the location of most data below the 'mantle array' in the Th-Sr isotope diagram (Fig. 2, inset). Mixing of a sedimentary component in the mantle source will also lead to higher $^{87}Sr/^{86}Sr$ ratios as schematically illustrated by the mixing curve. Most samples from 36 to 42° S have $^{87}Sr/^{86}Sr$ ratios around 0.7040, except for the basalt from Osorno, which has a slightly higher $^{87}Sr/^{86}Sr$ ratio and lower ($^{230}Th/^{232}Th$) ratio. Only a small contribution (<1%) of the sedimentary component is necessary to explain the thorium and strontium isotope data. Thus the $\delta^{18}O$ values will not be significantly affected in this process: they range from 5.7 to 6.0‰ and do not differ from normal mantle values. Only the high-K andesite from San Jose, north of 37° S, has higher $\delta^{18}O$ (6.5‰) and $^{87}Sr/^{86}Sr$ (0.7053): the magma in this volcano has probably been contaminated by old and ^{18}O-rich continental crust (Fig. 2, insert).

Previous results indicate that the relatively constant Pb isotope ratios in the SVZ lavas[9,10] can be explained neither by simple mixing of mantle material and presently subducted sediments, nor by a contamination from the continental crust[9]. But the introduction into the mantle of old and radiogenic sediments during the 200 Myr of convergence in this zone can produce the Pb isotope signature of the SVZ lavas. Radiogenic sediments could have been formed by erosion of the South America Precambrian craton and deposited by the rivers in the Pacific Ocean before the Andean orogeny. Another possible mechanism is the erosion of the Palaeozoic/Precambrian continental edge[12]. Thus the Pb isotope data does not contradict the model of a mantle source progressively modified by subducted sediments.

The limited variation of the different isotope ratios in the SVZ lavas suggest that this contribution is relatively constant between 37 and 41° S and that the mantle wedge is well mixed and isotopically homogeneous. Further south, however, Osorno has a distinctive Th and Sr isotope composition, indicating a greater contamination of its mantle source by ancient sediments, perhaps related to a thinner mantle wedge in this area.

These time-integrated modifications of the mantle wedge do not explain the origin of the ^{238}U enrichment over ^{230}Th, which obviously requires a recent (<300,000 yr) event in the mantle source. This uranium enrichment is not restricted to oceanic island arcs as previously suggested[8,13]. The fact that many subduction zone volcanoes lie on the right of the equiline in the isochron diagram is usually interpreted as reflecting the preferential uranium enrichment of the mantle wedge by slab-derived fluids before or during melting[14,15]. In this context it is particularly appropriate to compare ^{238}U-^{230}Th disequilibria and ^{10}Be results.

The presence of cosmogenic ^{10}Be in many lavas from young volcanic arcs and its total absence in MORB or OIB lavas

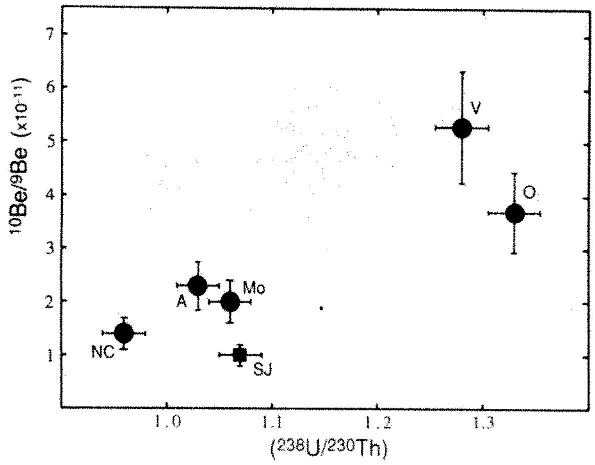

FIG. 3 Variation of $^{10}Be/^9Be$ with ($^{238}U/^{230}Th$) in the SVZ lavas. Abbreviations as in Fig. 2. Assuming a ^{10}Be-free mantle source, the extrapolation of this correlation to $^{10}Be/^9Be = 0$ can give the ($^{238}U/^{230}Th$) ratio of the primary melt before fluid addition. If this value is constant for all the SVZ primary magmas, then the maximum proportion of U added by fluids to the primary melt can be calculated for each volcano; it amounts to ~35% for Villarrica.

supports the proposition that subducted pelagic sediments, younger than 10 Myr, contribute to the formation of arc magmas[1-5]. Concentrations of ^{10}Be for the historic SVZ lavas analysed are given in Table 1 and these values (1.0-2.1×10^6 atom g^{-1}) are significantly higher than mantle or lower crustal values ($\ll 1 \times 10^6$ atom g^{-1}). They have been interpreted to reflect the incorporation of a subducted component during or before magma generation[2,5,6]. The ^{10}Be and (^{238}U/^{230}Th) ratios in SVZ lavas are compared in Fig. 3. Despite rather large analytical uncertainties in the ^{10}Be measurements, a fair correlation is apparent; the lavas having the highest uranium enrichment (south of 39° S) also exhibit the highest ^{10}Be/^{9}Be ratios. These results are in contrast to those from the New Britain arc[16,17], where highest ^{10}Be/^{9}Be are associated with highest (^{230}Th/^{232}Th) ratios, but are not well correlated with uranium excesses. The correlation between ^{10}Be/^{9}Be and (^{238}U/^{230}Th) in the SVZ samples is even better if we exclude the contaminated San Jose sample. The high ^{10}Be/^{9}Be ratios of the Villarrica and Osorno lavas can be attributed to the injection in the mantle of a greater amount of recent sediments. Indeed the extension towards the continent of the Valdivia Fracture Zone and 43° Fracture Zone (Fig. 1) which may act as sediment traps, pass directly beneath these volcanic centres. The absence of any correlation between Pb isotopes[9,10] and ^{10}Be/^{9}Be ratios confirms that, in contrast with ^{10}Be/^{9}Be ratios, the arc lead budget is the result of long-term modification of the mantle source by sediment subduction.

The correlation between ^{10}Be/^{9}Be and (^{238}U/^{230}Th) strongly suggests that a common process is responsible for the U and ^{10}Be enrichment. Boron probably accompanies ^{10}Be and U because ^{10}Be/^{9}Be and B/^{9}Be ratios are well correlated for SVZ lavas[6]. This process is most probably the recent dehydration of subducted sediments. The correlation also suggests that the U and ^{10}Be enrichments are related to the abundance of fluids and, therefore, to the amount of recently subducted sediments. The sediment subduction does not inhibit large earthquakes as evidenced by the great 1960 earthquake, which had its epicentre in this region of the Andes.

If the U and ^{10}Be enrichment is indeed the result of fluid transfer to the zone of magma generation in an otherwise homogeneous mantle source, then the nearly horizontal array in the isochron diagram (Fig. 2) has an age significance: it shows that the time interval between the fluid induced U-Th fractionation in the mantle and eruption of the magmas is ≤20,000 yr. Further discussion on the relative contributions of old and recent subducted sediments, mantle wedge and continental crust requires further data on other SVZ volcanoes, but our study demonstrates that U and ^{10}Be enrichments in the SVZ magmas are produced by the introduction in the mantle of fluids derived from sediments presently subducted under the Andes. ☐

Observations of seismic reflectors in the lower lithosphere beneath the Skagerrak

J. E. Lie, T. Pedersen & E. S. Husebye

Department of Geology, University of Oslo, PB Box 1047,
0316 Oslo 3, Norway

THE lithosphere—the rigid outer shell of the Earth—includes both the crust and the upper mantle. In the past decade, the complex continental crust and underlying shallower mantle lithosphere have been extensively studied using reflection seismology, but the lower lithosphere has not been successfully imaged. Here we report the observation of continuous and virtually horizontal reflectors in the lower continental lithosphere down to depths of 100–110 km below the Skagerrak (Scandinavia). These are apparently not structurally associated with the crust, whereas previously reported mantle reflectors, such as those observed by the BIRPS group around the British Isles[1,2], are often located near large faults in the overlying crust. Like the crust, the mantle lithosphere shows a seismically transparent upper and a reflective lower part. Thus, the processes that form seismic reflectors seem to have an affinity for ductile rheological environments in the mantle as well as in the crust. Our observations are consistent with a model consisting of a mechanically strong upper lithosphere, underlain by a thermal boundary layer which separates it from the convecting asthenosphere.

The roughly horizontal mantle reflectors were recorded on a 100-km-long experimental ultra-deep seismic reflection profile (OG-13) that was part of a comprehensive deep seismic survey (1,730 km; 16-s record length) conducted by the research vessel *Mobil Search* in the Skagerrak in 1987 (Fig. 1)[3]. A 40-s record length was used with a 4.5-km-long streamer having 180 hydrophone groups. The energy source was a 9,000-in^3 airgun array. As reflected energy is low for the large depths involved, much effort was put into processing refinements. After extensive experimentation, we chose a BIRPS processing scheme[4] except that we used a weighted trace mix in the common offset domain before stacking. The latter process gave a significant improvement of the data quality in the lower parts of the section as compared to more conventional extended-array simulations.

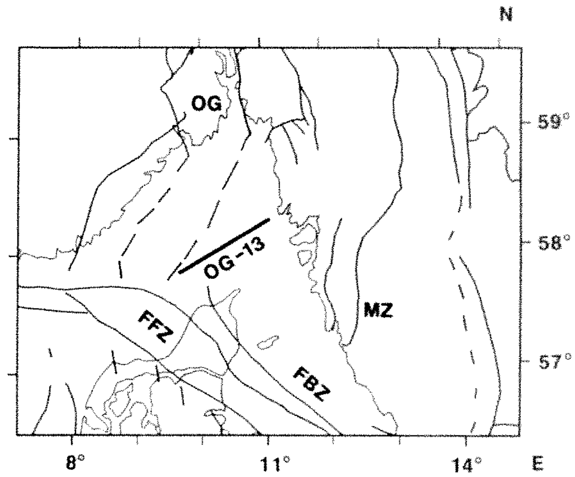

FIG. 1 Map showing the location of the deep seismic profiling line OG-13 in the Skagerrak. The principal geological features are outlined; OG: Oslo Graben; FBZ: Fennoscandian Border Zone; FFZ: Fjerritslev Fault Zone; MZ: Mylonite Zone.

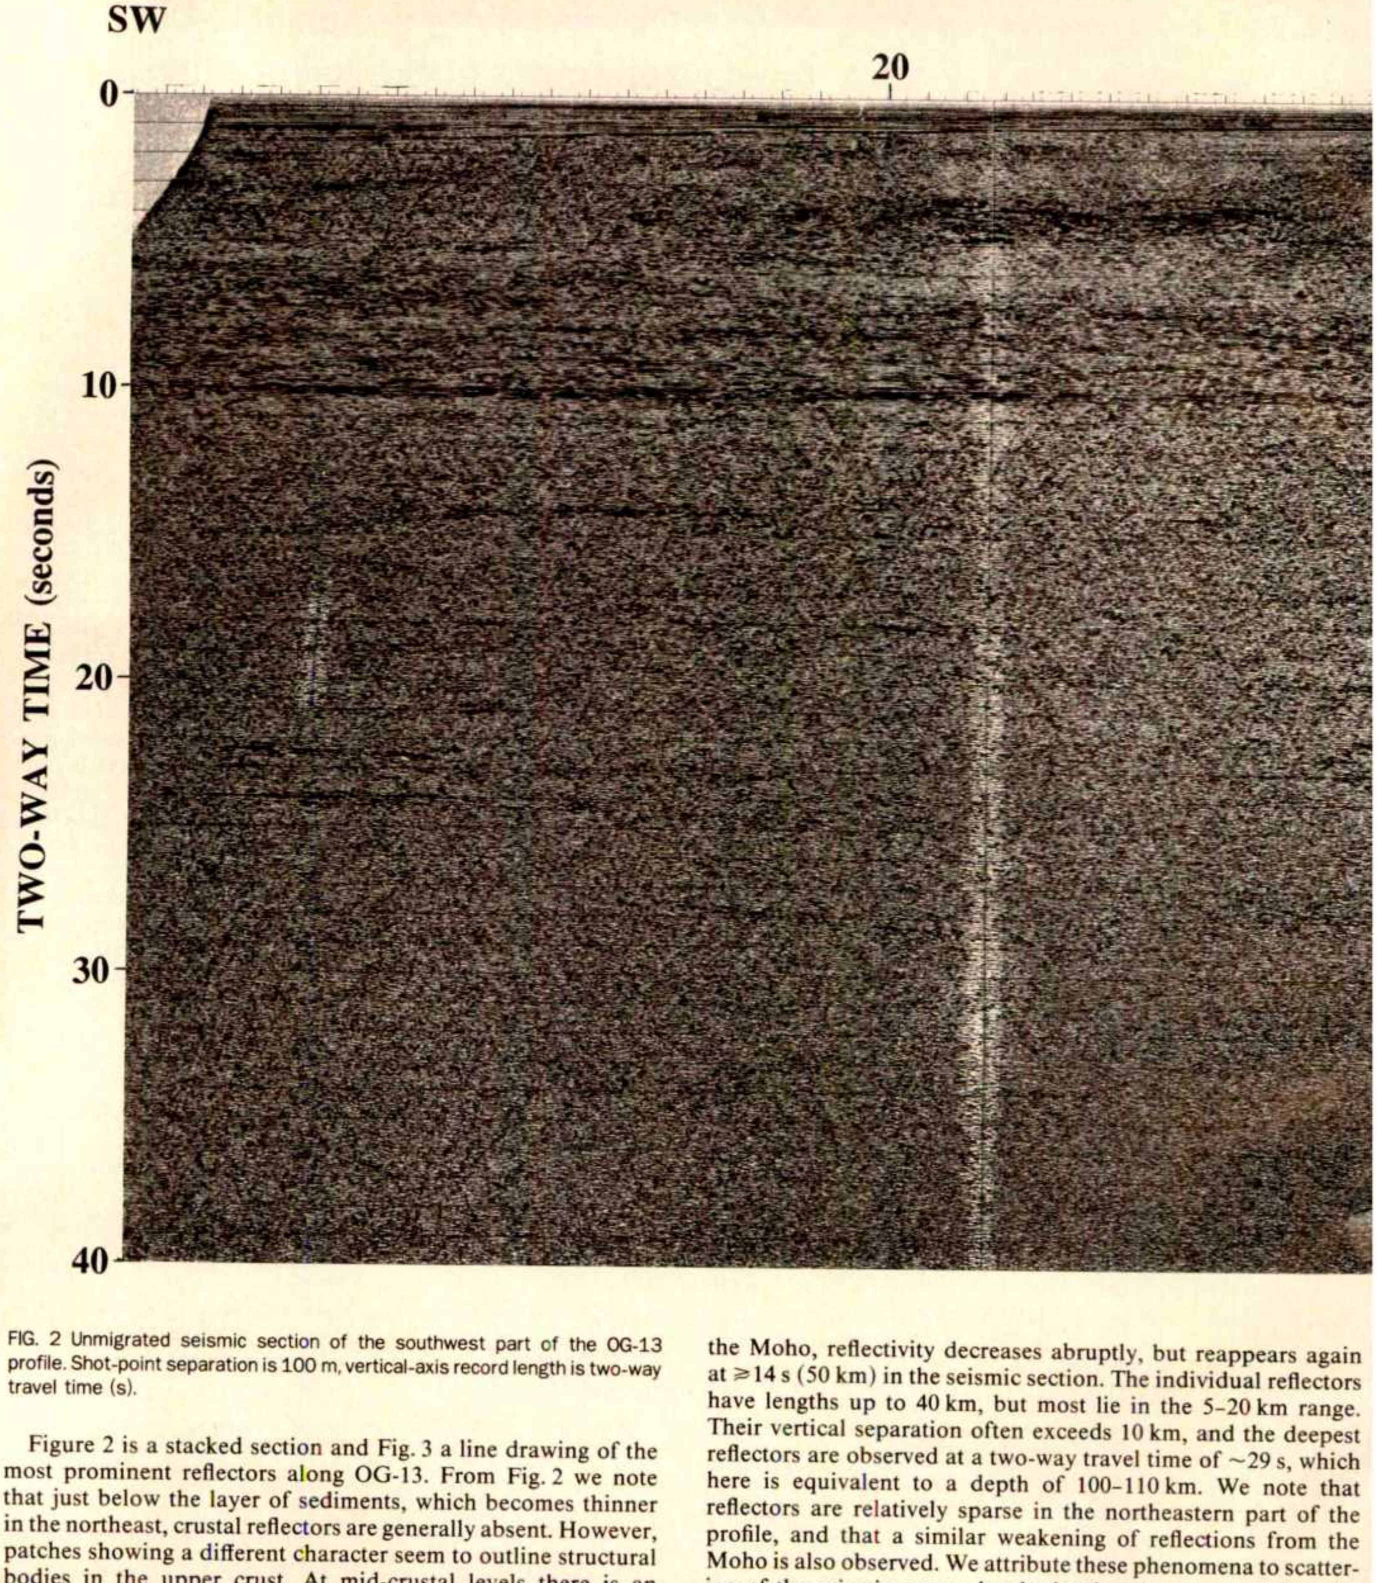

FIG. 2 Unmigrated seismic section of the southwest part of the OG-13 profile. Shot-point separation is 100 m, vertical-axis record length is two-way travel time (s).

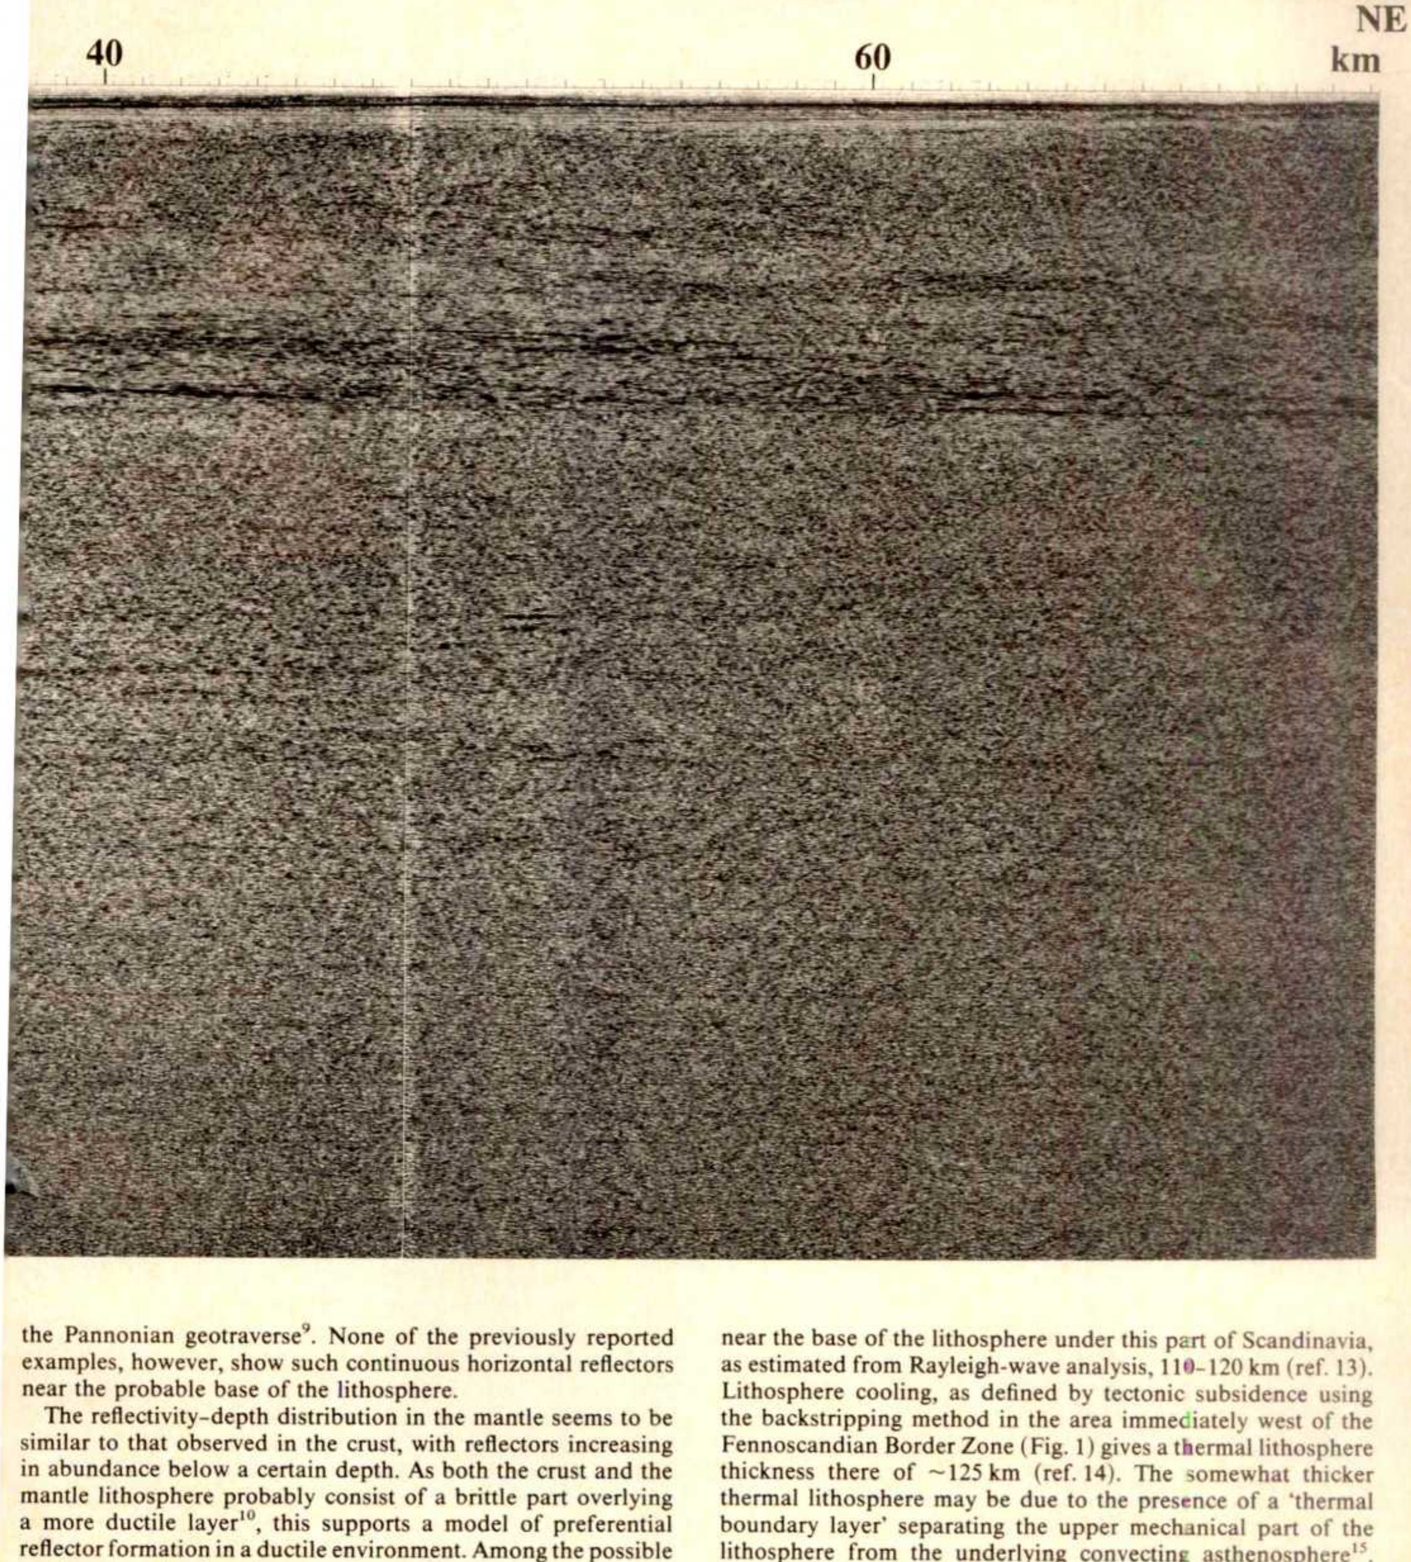
Figure 2 is a stacked section and Fig. 3 a line drawing of the most prominent reflectors along OG-13. From Fig. 2 we note that just below the layer of sediments, which becomes thinner in the northeast, crustal reflectors are generally absent. However, patches showing a different character seem to outline structural bodies in the upper crust. At mid-crustal levels there is an increase in reflectivity, which may mark the transition from an brittle upper to a ductile lower crust[5,6]. Lower crustal reflectors with individual lengths of a few kilometres often form lineaments 20-30 km long. The crustal reflectors seem to exhibit a distinct pattern that dips and thins towards the northeast where the crust thickens towards the centre of the Fennoscandian Shield. The reflective lower crust is bounded below by the 'reflection' Moho, which is well defined as an almost continuous reflective band ~200-400 ms (0.7-1.5 km) wide. Closer inspection reveals that the Moho at 10-s two-way travel time (~30 km) is laminated with 3-6 parallel segments, each typically 1-4 km long. Below the Moho, reflectivity decreases abruptly, but reappears again at ≥14 s (50 km) in the seismic section. The individual reflectors have lengths up to 40 km, but most lie in the 5-20 km range. Their vertical separation often exceeds 10 km, and the deepest reflectors are observed at a two-way travel time of ~29 s, which here is equivalent to a depth of 100-110 km. We note that reflectors are relatively sparse in the northeastern part of the profile, and that a similar weakening of reflections from the Moho is also observed. We attribute these phenomena to scattering of the seismic energy by the hard and uneven sea floor in this part of the section, where a sediment cover is lacking. In the western half of the section a possible candidate for a converted S-wave reflection from the Moho is observed and has been modelled to have an arrival time of 14 s. We note, however, that a similar observation of a potential S-wave converted reflection from the Moho, the W-reflector on the DRUM profile off northwest Scotland[1], was later proved to be a P-wave reflection and not an S-wave artefact by the SLAVE two-ship experiment[7].

The existence of reflectors 5-20 km long in the lower mantle lithosphere have rarely been reported. Notable exceptions are the MOIST and DRUM profiles off northeast Scotland[1,8] and



the Pannonian geotraverse[9]. None of the previously reported examples, however, show such continuous horizontal reflectors near the probable base of the lithosphere.

The reflectivity-depth distribution in the mantle seems to be similar to that observed in the crust, with reflectors increasing in abundance below a certain depth. As both the crust and the mantle lithosphere probably consist of a brittle part overlying a more ductile layer[10], this supports a model of preferential reflector formation in a ductile environment. Among the possible explanations that have been put forward for the large impedance contrasts needed to form mantle reflectors are the presence of shear zones containing layers of hydrated minerals, caused by the passage of water, and layers of mafic igneous material due to partial melting[1]. Alternatively the presence of shear strain may favour layers with oriented olivine or large amounts of garnet[11,12]. Such hypotheses have not yet been substantiated by quantitative modelling, however, and no objective criteria exist to discriminate amongst them using seismic data. As the nature of mantle reflections remains an enigma, we refrain from further speculations on their character in the Skagerrak area.

The deepest reflections identified, at ~100–110 km depth, are near the base of the lithosphere under this part of Scandinavia, as estimated from Rayleigh-wave analysis, 110–120 km (ref. 13). Lithosphere cooling, as defined by tectonic subsidence using the backstripping method in the area immediately west of the Fennoscandian Border Zone (Fig. 1) gives a thermal lithosphere thickness there of ~125 km (ref. 14). The somewhat thicker thermal lithosphere may be due to the presence of a 'thermal boundary layer' separating the upper mechanical part of the lithosphere from the underlying convecting asthenosphere[15]. Whereas the mechanical part is capable of preserving structural and compositional features on a geological timescale, these are smeared out in the thermal boundary layer owing to episodic convection. Consequently, we do not expect to observe any reflectors there. It is also possible that the lack of observed reflectors is related to the limited dynamic range of the recording system and limited strength of the airgun signal, but it seems unlikely that the 'penetration depth' so defined should agree so well with lithosphere thickness as estimated by other and independent methods.

Our results indicate that the base of the lithosphere can be mapped using the seismic-reflection technique. Such results,

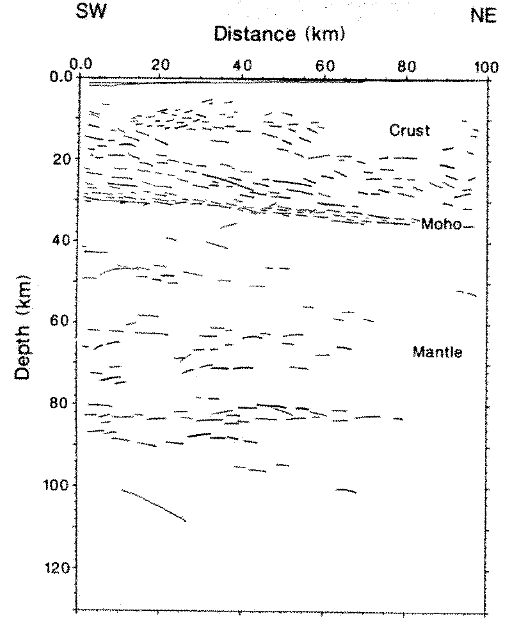


FIG. 3 Line drawing derived from the time-to-depth conversion of the unmigrated stack section using a simple velocity model.

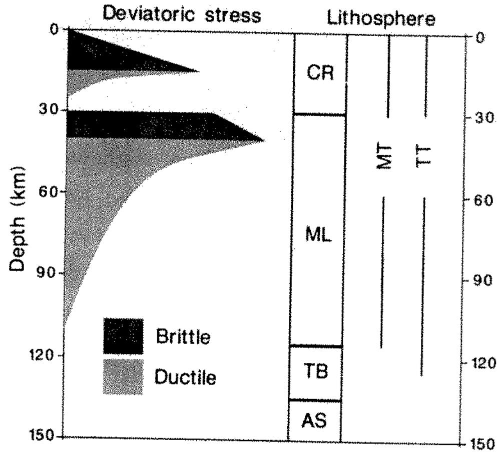

FIG. 4 Sketch of the lithosphere in the OG-profiling area. CR, crust; ML, lower lithosphere; TB, thermal boundary layer; AS, asthenosphere; MT, mechanical lithospheric thickness; TT, thermal lithospheric thickness. Deviatoric stress (relative scaling) calculated for a lithosphere rheology with quartz in the crust and olivine in the mantle lithosphere. The brittle and ductile regions are indicated. The thermally defined lithosphere is thicker than the one estimated from surface-wave analysis owing to the presence of the thermal boundary layer.

combined with data from other geophysical methods, may ultimately help us to improve our understanding of the nature of the lithosphere, its transition to the asthenosphere and the part it plays in plate tectonics. ☐

Liquid immiscibility in a nephelinite–carbonate system at 25 kbar and implications for carbonatite origin

Michael B. Baker & Peter J. Wyllie

Division of Geological and Planetary Sciences, California Institute of Technology, Pasadena, California 91125, USA

MANTLE-DERIVED carbonate-rich melts may have an important role in mantle metasomatism[1,2], and may serve as parent liquids for crustal carbonatite magmas[3,4]. Experiments have shown that carbonatitic melts can be produced by partial melting of peridotite + CO_2 + H_2O above 22 kbar (ref. 3), and that silicate and carbonate liquids are immiscible between 2 and 15 kbar for a wide range of Ca/Na ratios[5–7]. We have determined the extent of silicate-carbonate liquid immiscibility at 25 kbar and 1,050–1,300 °C using mixtures of magnesian nephelinite, dolomite and sodium carbonate with and without water. In contrast to the low-pressure data, the two-liquid field at 25 kbar is restricted to more sodium-rich compositions, far removed from natural mantle melts. Our experimental results suggest that neither partial melting of carbonated peridotite, nor extensive fractional crystallization of silicate magmas at depths corresponding to 25 kbar, are likely to generate carbonatitic magmas by liquid immiscibility.

High-pressure melting studies in the system $CaO-MgO-SiO_2-CO_2$ have shown that initial liquids will be dominated by calcic dolomite (Ca/Mg > 1) and will have ~5–10 wt% silicate components[8,9]. In natural peridotites sodium will be strongly partitioned into this carbonatitic liquid[3,10]. None of these high-pressure melting studies, however, has demonstrated silicate-carbonate liquid immiscibility. Mixtures of kimberlite and calcite with and without H_2O did not show liquid immiscibility over a temperature and pressure range of 1,250–1,500 °C and 20–30 kbar (ref. 11). In vapour-saturated peridotite melting experiments above 31 kbar, Wallace and Green[3] reported possible silicate-carbonate liquid immiscibility at ~1,000 °C. Our study was undertaken to define the extent of silicate-carbonate liquid immiscibility over a range of temperatures and compositions at 25 kbar. Starting mixtures contained 30–50 wt% of a de-watered primitive nephelinite (Neph) from the Honolulu Volcanic field, Hawaii (68KEE-1)[12]. The remaining 50–70 wt% consisted of carbonate with ratios of dolomite (Dol) and Na_2CO_3 between 0 and 3. Mixtures with the same major-element compositions and containing 4.5 wt% H_2O were made up from combinations of oxides, carbonates and synthetic and natural minerals. Water was added in the form of $Mg(OH)_2$ and $Al(OH)_3$; 4.5 wt% was selected as a reasonable upper limit for mantle melts. A mixture consisting of 44 wt% nephelinite, 6 wt% Durango apatite and 50 wt% Na_2CO_3 was used to investigate the effects of P_2O_5 on immiscibility. All starting mixtures were dried for at least 1 h in a vacuum drying oven at 110 °C before being loaded into graphite crucibles, which were sealed inside platinum capsules. Although not rigorously buffered, experimental calibration sug-

* Number of analyses.

† Values in parentheses are standard deviations of the mean, that is, 9.5 (1) means 9.5 ± 0.1.

All liquids reported on a CO_2-free basis, normalized to 100%. Bulk compositions: 116 = 0.5Neph + $0.5Na_2CO_3$; 110 = 0.44Neph + 0.06Ap + $0.5Na_2CO_3$; 157 = 0.5Neph + $0.5Na_2CO_3$ + 4.5% H_2O. Abbreviations: Carb, carbonate liquid; Sil, silicate liquid; Neph, nephelinite; Ap, apatite.

gests that the oxygen fugacity in the graphite capsules was in the wüstite field[13].

Experiments were performed in a 1.27-cm piston-cylinder apparatus using calcium fluoride as a pressure medium. For the anhydrous starting compositions a series of timed experiments showed that a minimum of 6–8 h was required to approach two-liquid equilibrium. The hydrous experiments were run for 1–6 h. Products were polished without using water, and were analysed with a Camscan scanning electron microscope (SEM) fitted with an energy dispersive system. Quenched liquids and crystals were analysed using a beam current of 0.1 nA on brass. All of the liquids quenched to a fine intergrowth of carbonate and silicate material. The quenched liquids were analysed 9–11 times in raster mode; each analysis covered several hundred square micrometres. Liquid compositions from selected experiments are reported in Table 1.

Figure 1*a* shows the results of the 25-kbar nominally anhydrous experiments on the nephelinite–dolomite–sodium carbonate join. Liquids and starting compositions have been projected from CO_2 onto the plane ($SiO_2 + Al_2O_3 + TiO_2$)–($CaO + MgO + FeO^*$)–($Na_2O + K_2O$). This simple oxide wt% projection has been used extensively to display silicate and carbonate liquids at low to moderate pressures[6]. Also shown in Fig. 1*a* are the coexisting silicate and carbonate liquids in the systems sanidine–K_2CO_3 (ref. 14) and albite–Na_2CO_3 (D. Ellis and P.J.W., unpublished data), and the 5-kbar immiscibility field[6]. At 1,300 and 1,250 °C the two-liquid field is located in the sodium-rich portion of composition space. For both temperatures, the immiscibility field is broadest for mixture 1 (Dol/Na_2CO_3 = 0) and the field closes with increasing dolomite content. The field also widens with decreasing temperature.

At 1,250 °C both the mixture 1 (Dol/Na_2CO_3 = 0) and mixture 2 (Dol/Na_2CO_3 = 0.33) form two liquids. In both charges the silicate fraction forms a large spheroid (<800 μm in longest dimension) and is surrounded by carbonate melt. At 1,250 °C the silicate fraction in the mixture 1 experiment contains olivine

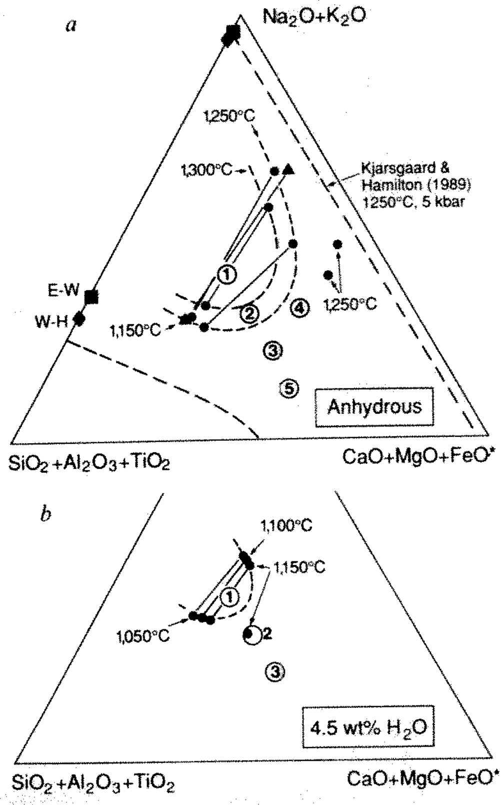

FIG. 1 Run products and starting compositions projected from $CO_2 \pm H_2O$ onto the plane ($SiO_2 + Al_2O_3 + TiO_2$)–($CaO + MgO + FeO^*$)–($Na_2O + K_2O$). FeO* is total Fe as FeO. Open circles denote starting mixtures: 1, 0.5Neph + $0.5Na_2CO_3$; 2, 0.5Neph + $0.375Na_2CO_3$ + 0.125Dol; 3, 0.5Neph + $0.25Na_2CO_3$ + 0.25Dol; 4, 0.3Neph + $0.35Na_2CO_3$ + 0.35Dol; 5, 0.5Neph + $0.125Na_2CO_3$ + 0.375Dol; abbreviations as in Table 1 and Dol, dolomite. *a*, Anhydrous experiments; closed symbols denote liquid compositions, triangles denote liquids from mixture 1 + 6% apatite experiment at 1,150 °C. Long dashes denote 5-kbar two-liquid field from Kjarsgaard and Hamilton[6]; W-H denotes experimental liquid from Wendlandt and Harrison[14]. E-W denotes experimental liquid from D. Ellis and P.J.W. (unpublished data). *b*, Results from experiments with 4.5 wt% H_2O; open circle denotes same starting mixtures as in *a* but containing 4.5 wt% H_2O; other symbols are the same as in *a*. Because of the closely spaced liquid compositions only one two-liquid field is shown.

the silicate fraction in the mixture 1 experiment contains olivine (86% fosterite, Fo_{86}) and aluminous spinel, and has ~34 wt% SiO_2 and ~30 wt% Na_2O (CO_2-free basis). SiO_2 and Na_2O values in the coexisting carbonate liquid are ~10 and 61 wt%, respectively. Olivine (Fo_{86}) and spinel are more abundant in the experiment with mixture 2 at 1,250 °C. Runs using mixtures 3 and 4 (both with $Dol/Na_2CO_3 = 1$) produced olivine, clinopyroxene, spinel and carbonated silicate liquids at 1,250 °C. Clinopyroxene dominates the crystalline assemblage in both runs and the resulting liquids are driven toward the (Na_2O+K_2O+K_2O)-(CaO+MgO+FeO*) join. Mixture 5 with $Dol/Na_2CO_3 = 3$ was largely crystalline at 1,250 °C, and the small pockets of liquid could not be analysed using SEM area scans.

The 1,150 °C tie line defines the extent of immiscibility in the mixture 1+6% apatite ($Dol/Na_2CO_3 = 0$). The silicate fraction contains olivine (Fo_{83}) and spinel. Although the two-liquid field has expanded slightly relative to the 1,250 °C boundary, this may simply reflect the 100 °C drop in temperature. Apatite does not seem to have a large effect on the size of the two-liquid field. For a variety of compositions, the silicate-carbonate immiscibility field extends from the (SiO_2+Al_2O_3+TiO_2)-(Na_2O+K_2O) join to close to the CaO+MgO+FeO* corner at crustal pressures (Fig. 1*a*). The decrease in the size of the anhydrous two-liquid field at 25 kbar compared to 5 kbar must reflect the increasing solubility of dolomite in silicate liquids with increasing pressure.

Figure 1*b* shows the results of the hydrous experiments. Runs using mixture 1+4.5% H_2O ($Dol/Na_2CO_3 = 0$) display immiscibility over the range of investigated temperatures (1,200-1,050 °C). At the lowest temperature the two liquids coexist with olivine. Experiments using mixture 2+4.5% H_2O ($Dol/Na_2CO_3 = 0.33$) contain a single liquid and minor olivine at 1,150 °C and a single liquid, olivine (Fo_{86}) and amphibole at 1,100 °C. Although we have not run experiments down to 950 °C, the solidus of fertile peridotite+vapour[3], we do not expect the two-liquid field to expand significantly between 1,050 and 950 °C. Further, below, 1,100 °C increasing crystallization of olivine+amphibole±clinopyroxene will drive residual liquids toward the (Na_2O+K_2O)-(CaO+MgO+FeO*) join and out of the immiscibility field.

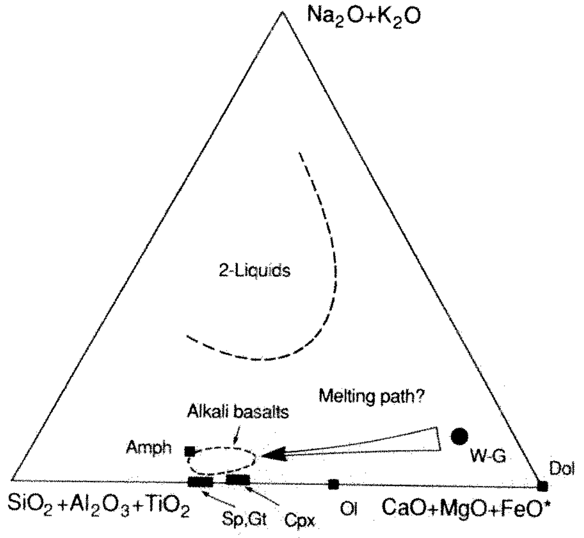

FIG. 2 Anhydrous 25-kbar two-liquid field and an inferred melting path for amphibole+dolomite peridotite projected onto the (SiO_2+Al_2O_3+TiO_2)-(CaO+MgO+FeO*)-(Na_2O+K_2O) plane. W-G denotes the carbonate liquid composition (Table 1, column 3)[3]; alkali basalt field[12,15]; squares and rectangles denote minerals that could crystallize from carbonate-rich liquids: olivine (Ol) and spinel (Sp) from this study, amphibole (Amph) from Wallace and Green[3], garnet (Gt) and clinopyroxene (Cpx) from M.B.B. and P.J.W. (unpublished data).

Silica, titania, alumina and iron are enriched in the silicate relative to the carbonate liquid (Table 1). The behaviour of titanium and aluminium indicates that phases such as ilmenite, spinel and garnet will have relatively low solubilities in carbonate melts. Thus partial melting of dolomite-bearing peridotite may be an effective mechanism for fractionating high-field-strength elements from other incompatible elements and light from heavy rare-earth elements. Calcium, sodium and phosphorus are enriched in the carbonate relative to the silicate liquids. In the anhydrous experiments K_2O is partitioned into the carbonate liquid, whereas in the runs with water K_2O is enriched in the silicate liquid.

Figure 2 shows the anhydrous 1,250 °C two-liquid field projected onto the (SiO_2+Al_2O_3+TiO_2)-(CaO+MgO+FeO*)-(Na_2O+K_2O) plane. The point labelled W-G is the carbonatitic melt produced by Wallace and Green[3] at 1,000 °C and 22 kbar and in equilibrium with olivine, orthopyroxene, clinopyroxene, amphibole, spinel and ilmenite. The region labelled alkali basalts includes a variety of nepheline normative liquids with Mg/(Mg+Fe*) ratios > 0.66 (refs 12, 15). These basaltic compositions are generally assumed to represent partial melts from a garnet peridotite source[16,17]. Figure 2 shows that a projected straight-line melting path from W-G to the alkali basaltic field does not intersect the two-liquid field. Note that the path is curved in CO_2 space because volatile contents decrease with increasing melt fraction; W-G contains ~45 wt% volatiles whereas most alkali basalts probably have <5 wt% H_2O and CO_2. There is no reason, however, to expect projected melting paths to curve toward the Na_2O+K_2O corner. Thus it seems unlikely that immiscible silicate and carbonate liquids can be directly produced by vapour-undersaturated partial melting of hydrated dolomite peridotite at pressures of ~25 kbar. Also plotted on Fig. 2 are the compositions of olivine, clinopyroxene, amphibole, garnet, spinel and dolomite that could fractionate from carbonate-rich liquids. Residual liquids could only reach the two-liquid field after appreciable crystallization of dolomite and olivine.

Based on our vapour-undersaturated experiments we conclude that carbonatitic melts are unlikely to be produced by immiscible exsolution from carbonated silicate liquids at pressures between 20 and 30 kbar. The immiscibility field in both sets of experiments is far removed from natural mantle melts. We do not expect the presence of excess vapour to modify this conclusion. High-pressure partial melting and liquid immiscibility at lower pressures, however, remain viable processes for generating carbonatitic melts. We are now measuring how the immiscibility field expands with decreasing pressure. We anticipate that carbonated silicate melts derived at higher pressures may intersect a two-liquid field between 10 and 20 kbar[5-7]. ☐

Macromolecular resolution of fossilized muscle tissue from an elopomorph fish

David M. Martill

Department of Earth Sciences, The Open University,
Milton Keynes MK7 6AA, UK

THE Santana Formation (Lower Cretaceous, Aptian/Lower Albian) of Ceara, Brazil, contains many exceptionally preserved fish fossils within carbonate concretions[1,2]. These concretions formed before compaction of the sediment and nucleated around carcasses of fish killed in mass-mortality events. Some concretions may contain several fish, preserved in three dimensions with fully articulated skeletons[1]. A few specimens contain calcium phosphate in the form of cryptocrystalline hydroxyapatite. This occurs as coatings on bones and as a replacement of tissues. Samples of mineralized soft tissues can easily be liberated from the concretions by immersion in 10% acetic acid[3]. Of several mineral phases often preserving soft tissues, calcium phosphate and silica probably offer the greatest resolution of detail[4]. Fossilized soft tissues are most frequently found in fishes, although in the Santana Formation pterosaur wing membrane[5] and the cuticles of arthropods[6,7] have been reported. I report here the study of striated muscle tissue from a fossil elopomorph fish[8] from this formation, in which subcellular ultrastructural features are distinguishable. The exceptional degree of preservation of the specimen raises interesting questions about the mechanism of fossilization.

A specimen of the elopomorph fish[8] *Notelops brama* (Agassiz) in which phosphatization of soft tissues has been extensive, indicates that preservation occurred at the macromolecular level before and during postmortem degradation of the tissues[9]. This resulted in the detailed replacement of structures at the subcellular level in some tissue types. This is most marked in phosphatized striated muscle tissue, where individual muscle fibres are preserved. The muscle fibres are replaced by phosphate in which individual crystallites are less than 100 nm long. Crystallites may be aggregated into microspheres with diameters of 1-2 µm, or as roughly cubic aggregates 0.7-0.8 µm in diameter. In the latter case, preserved muscle fibres show excellent detail of ultrastructure. Here crystallite orientation seems to have been controlled by the orientation of structural proteins, and other biomacromolecules within the fibres. The most obvious result of this is the retention of the sarcomeres in striated muscle fibres (Fig. 1*a*). This fossil banding, equivalent to the I and A bands of modern striated muscle, is highlighted by parallel rows of paired hydroxyapatite crystallite aggregates (Fig. 1*b*). The boundary between crystallites within crystallite pairs may correspond to the H band of individual sarcomeres, whereas the boundary between adjacent crystallite pairs may represent the Z band. Sarcomere length in the fossil material is ~2 µm in compact fibres. Some fibres show that separation between lithified sarcomeres has occurred, but this is most likely a post-lithification artefact. The process of phosphatization took place during active decomposition of the muscle fibres, and individual fibrils can frequently be observed.

Other ultrastructural features of the muscle fibres which have been preserved include the sarcolemma (Fig. 1*c*) and rows of cell nuclei along the muscle fibre surfaces (Fig. 1*d*). In the former case there is sometimes no phosphatization of the enclosed muscle fibre, resulting in a stack of phosphatized sarcolemma membranes. The length of muscle fibres varies according to the size of the fish, and hence to the length of individual myoseptal blocks. Fibre diameter is generally of the order of 50 µm, and preserved sarcolemma is ~1 µm thick. Cell nuclei have been observed on several muscle fibres. The nuclei are ovoid, ~8 µm long and 4 µm in diameter, and arranged

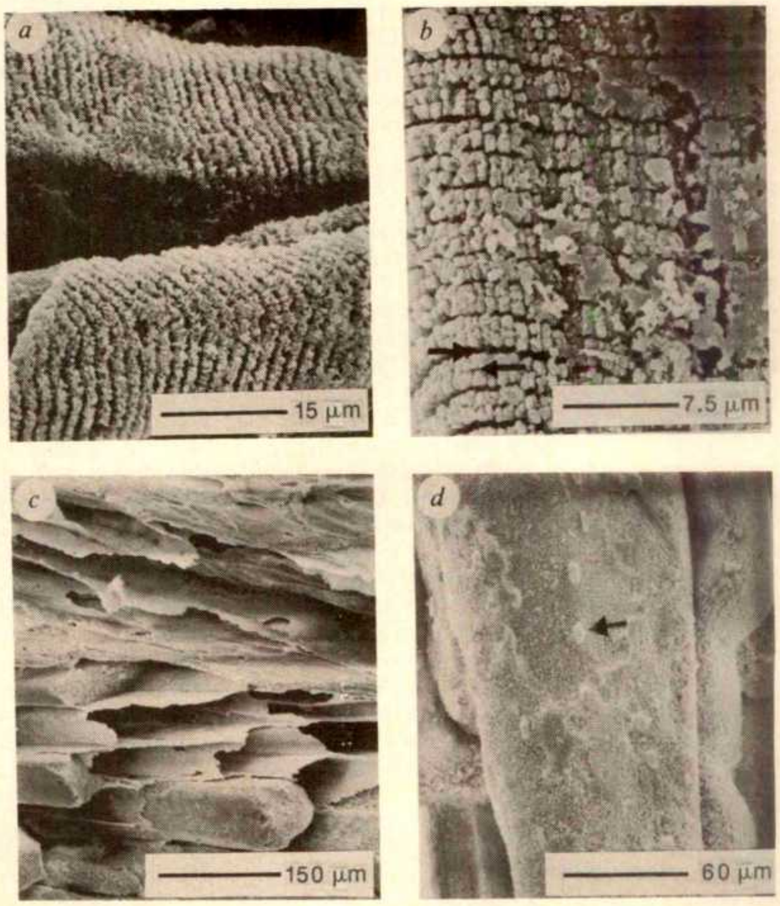

FIG. 1 Scanning electron micrographs of soft tissues from the Cretaceous actinopterygian fish *Notelops brama* (Agassiz), preserved by metasomatic replacement with calcium phosphate and prepared in 10% acetic acid. *a*, Two striated muscle fibres showing well-preserved banding. *b*, Detail of sarcomere preservation showing individual crystallite aggregates of calcium phosphate arranged in pairs; arrows indicate zones interpreted as H and Z bands. *c*, Unusual situation where preservation of sarcolemma has occurred, but preservation of fibres is incomplete. The result is a block of three-dimensionally preserved cell membranes. *d*, Striated muscle fibre showing patches of preserved sarcolemma, sarcomeres and rows of cell nuclei (arrowed).

in rows with long axes parallel to the length of the muscle fibre.

The presence of exceptionally preserved soft tissues raises several questions regarding both the rate and mechanism of fossilization. Many models for exceptional preservation require rapid burial, anoxicity, or both[10-12]. There is evidence for scavenging of many of the exceptionally preserved Santana specimens suggesting that anoxic and rapid burial models are not applicable here. The Santana fossils are associated with laminated organic material, and I suggest that bacterial sealing as proposed by Seilacher *et al.*[11] is a more appropriate model for their exceptional preservation.

Bacterial breakdown of soft tissues might be inhibited by sterilization of bottom waters by high salinity or very low temperatures, thus prolonging their availability for the slow process of fossilization. At a palaeolatitude of 10° S, the Santana Basin was unlikely to have been floored by very cold water, but bottom water of high salinity may have been present[1] as evaporites occur below.

For soft tissues to be so well preserved mineralization must either take place rapidly (in hours rather than days) or bacterial decomposition must be inhibited[12]. Most models regard inhibition of bacterial decomposition as an acceptable mechanism; keeping the soft tissues 'on ice' while fossilization takes place. Gill and muscle degrade rapidly after death; within the first hour such tissues lose their regidity and may display collapse structures. Santana fossil tissues show preservation of these features, suggesting that phosphatization occurred during active decomposition[9].

The mechanism of phosphatization is not fully understood. It may in part be analogous to the biomineralization process in vertebrates. Here, ultramicroscopic crystallites of apatite nucleate within specific sites in collagen or collagen-like proteins[13]. This mechanism is a possibility for the fossil fish because of the abundance of tissues rich in structural proteins. But phosphatizing bacteria have been reported in sediments, where they have an important role in the production of phosphorites[14]. Shapiro[15] demonstrated that environmental fluctuations (changes in temperature and/or oxygen levels) can induce rapid precipitation of phosphate by microorganisms, and a similar bacterially mediated process may be important in the fossilization of soft tissues[1,16]. ☐

Experimental reversal of courtship roles in an insect

D. T. Gwynne* & L. W. Simmons†

* Department of Zoology, Erindale College,
University of Toronto, Missassauga, Ontario L5L 1C6, Canada
† Department of Environmental & Evolutionary Biology,
University of Liverpool, PO Box 147, Liverpool L69 3BX, UK

STUDIES of sexual selection[1] commonly examine female mating preferences or intermale competition[2], but there have been few experimental tests of factors controlling why these, the 'typical courtship roles', exist in the first place. Although the distribution of mates can affect sexual selection, and thus the degree of sexual competition[3], it is the typically lower investment in offspring by males relative to females that is thought to determine the usually greater potential mating frequency, and hence greater sexual competition, among males[4,5]. Reversal in the typical courtship roles is, therefore, expected to occur where there is high male parental investment[4]. The courtship roles are generally considered to be fixed for any particular species because of the usually inflexible nature of adaptations for parental care. Certain katydids (Orthoptera: Tettigoniidae)[6-8], however, show intraspecific variation in these roles. This has been suggested to result from variation in the relative importance of male parental investment[9] in the production of offspring. Male parental investment comprises the nutritional value of the spermotophore eaten by the female. When other food is scarce therefore, females are predicted to compete sexually for males and their offerings[7,8,10]. Here we confirm this prediction and show that an increase in food from a low level results in a change from role-reversal to the typical roles; this supports the theory[4,5] that variation in relative male parental investment controls sexual differences.

Both male and female katydids invest parentally in eggs. The male transfers a meal consisting of the spermatophylax (part of the spermatophore) to his mate, the nutrients of which are translocated to eggs[11] and increase both number and fitness of offspring sired[9,12,13]. For several species, the fitness-enhancing benefits to females of this costly[13-15] nutrient gift have apparently led to sexual selection among females associated with both mate choice by males and inter-female aggression[6-8,16]. In these species, however, this courtship role-reversal is found only in certain populations. Such a role-reversal is argued to be controlled by food availability[6-8] because a scarcity of food: (1) decreases the number of sexually active males and thus their large spermatophylax contributions; and (2) increases the mating (spermatophylax-acquiring) frequency of hungry females[15]. Therefore, with such a decrease in food availability in nature, males rather than females are predicted to be the choosy sex because of the relative scarcity of males that have gained enough nutrients to donate parental investment. Because of the cost of the male contribution[13-15] (ultimately in terms of future offspring sired[5,9]), its enhanced value represents an increase in relative male parental investment[7,10]. An experimental test of the hypothesis that diet controls sexual differences would, therefore, represent a test of the influence of relative parental investment.

The subject is an undescribed genus and species of zaprochiline katydid that feeds only on the pollen of certain spring-flowering plants[17,18]. Large numbers of feeding individuals and sexually signalling (calling) males can be found on a single food plant[18]. In nature the species showed a courtship role-reversal early in the season when feeding from flowers, particularly kangaroo paws (*Anigozanthos manglesii*), that seemed to produce relatively little pollen. Later in the season, when there was an abundance of pollen available on the long flower spikes of *Xanthorrhoea preissei*, fewer females were mating and females became choosier than males[8]. Although this switch in mating system was correlated with an apparent increase in pollen availability, alternative causal explanations, such as a decrease in mating activity by older females, are plausible[8].

In the present experiments, the effects of such variables were controlled by directly manipulating the amount of pollen available; during the flowering of kangaroo paws early in the season, four caged populations of katydids received supplemental food and four served as controls (Table 1).

TABLE 1 Differences between control and supplemental food treatments

		Males		Females				Sexual behaviour

The species is catalogued in the Australian National Insect Collection (ANIC) as Gen. Nov. 22, sp. 1 of the Zaprochilinae (D. C. F. Rentz, in preparation). (Voucher specimens were deposited in the ANIC[18].) The study site, also that of previous studies[8,18] is native bush of King's Park, Western Australia[23]. We placed cuboidal fibreglass-screened cages, 0.75 m linear dimensions, over eight clumps of flowering kangaroo paws for 14 days in September 1989. Four cages were randomly selected as supplemental food replicates and into each were placed two artificial *X. preissei* flower spikes produced by coating the distal 15–20 cm of dried sections of flower stalks first with dilute honey, then pollen (bee-collected from Western Australian plants). The remaining four cages were controls receiving only the dried stalks. We placed individually marked zaprochilines, 24 of each sex, into each cage (such densities occur in nature). The behaviour of insects in one replicate of each treatment was observed each evening for a total of 12 sampling days. Observations on focal cages were made from sunset (~18:30) until ~22:00, the period of mating activity[8]. At about 20:30 each day (except one, lost due to rain), we censused the calling males and mated (spermatophore-carrying) females in each of the nonfocal cages. They seemed to behave naturally in the cages; as in nature[8,18], almost all calling males perched on the stems of food plants allowing the observer unobstructed views (using red light) of sexual interactions. At the end of the experiment all insects were collected and later measured and dissected to determine fecundity, weight of (two randomly selected) eggs, and spermatophore gland weight.

Mating in this species begins when a receptive female mounts a male after responding to his ultrasonic call[18]. After coupling the male bends behind the female and the spermatophore is transferred several minutes later. Following separation the female bends and starts to eat the gelatinous spermatophylax which surrounds the ampulla[8,18] (the ampulla transfers sperm into the female). Mate rejection was recorded if the male or female moved away from its partner before spermatophore transfer[8]. Following rejection by a male, females often followed the male and recoupling sometimes occurred. In the case where a female rejected a male, males groped their terminalia in the direction of the retreating female. Only males can reject mates after pairs have coupled genitalia[8]. Sexual competition between females occurs when two females grapple either while responding to the same calling male or after a female disrupts a mating pair. No fighting between males has been noted in this species but it is possible that competition occurs through acoustical displays[8,18].

The results were as predicted. As for unmanipulated field populations[8], there was a reversal in the courtship roles when the only food available to zaprochilines was pollen from kangaroo paws (control); such a reversal was not evident when the katydids received supplemental pollen. Quantitative results are presented in Table 1. To maintain statistical independence, if individuals were represented in more than one interaction only one (randomly determined) interaction was used. Fights between females over males were observed in control cages but never in food-supplemented cages. The frequency of rejection of females by males was significantly higher in the control cages, whereas the rejection of mates by females was most frequent in food-supplemented cages.

Courtship role-reversal in control cages was due to the predicted presence of fewer sexually active males than females; there were significantly fewer calling males in control cages than in food-supplemented cages. The greater proportion of sexually active males in supplemented cages was a result of the increase in the number of males obtaining sufficient pollen to produce spermatophylax donations. This is evidenced by the significantly larger spermatophore-producing glands of food-supplemented males relative to control males. After mating, male katydids call only when the spermatophore glands have been replenished[13] (even when starved, such males do not reduce the size of the subsequent spermatophore[15]). The difference between treatments in the ratio of sexually available females and males is due apparently both to the increase in spermatophore production by food-supplemented males and to the decrease in the mating (spermatophylax-acquiring) frequency of the now food-sated females in this treatment. The number of matings by females in supplemented cages was about half that observed in controls. This accords with observations of female zaprochilines on varying unmanipulated diets in the field[8]. Fecundity and egg size are increased both by additional spermatophylax[13] and apparently by additional pollen[8] eaten, so the higher mating frequency of control females probably acts to increase fecundity. Additional courtship meals in our experiments, however, did not seem completely to compensate for the decreased availability of pollen because control females had lower fecundities and smaller mature eggs compared to food-supplemented females (Table 1).

The opportunity for sexual selection to favour particular females was estimated in a between-treatment comparison of the distributions of variances in female mating success ($s^2/\bar{x}$) (refs 19, 20). As predicted, variances were significantly higher in control than supplemented cages. The body mass of females is expected to be a sexually selected trait as males of this[8] and other katydids[7,16] prefer heavier, more fecund females and larger female zaprochilines usually win fights over pollen[8]. Thus we predicted a mating advantage for heavy females in control but not in food-supplemented cages. This prediction was supported. The regression of body mass on mating frequency was significant for the control (slope = 0.09, $r^2=0.10$, $F_{1,85}=9.6$, $P=0.003$) but not for supplemented cages (slope = −0.01, $r^2=0.01$, $F_{1,78}=0.9$, $P=0.34$) (the four replicates within each treatment were pooled after showing that slopes within treatments were homogeneous ($P>0.05$)). Such a relationship in low cages is, however, predicted not only by the mating success hypothesis but also by the fact that more courtship meals (matings) may increase female mass.

A decrease in pollen available to the zaprochilines causes male parental investment in the nutritious spermatophore to increase in value for offspring production. This change in value does not, however, result in an increase in female choice of males able to supply high quality donations because there is no opportunity for such choice as a result of the large reduction in the proportion of nurturant males. This relative scarcity of males is caused not only by the fact that few males have obtained enough pollen to produce a spermatophore, but also by an increase in mating frequency of females as they seek additional courtship meals[15]. Thus females are subjected to heightened sexual selection associated both with fights between females for access to nurturant males and with mate choice by males. We conclude that the facultative nature of courtship roles in this species results from variation in the relative importance of male parental investment. The results refute alternative explanations for similar behavioural variation in nature[6,8], including the suggestion that such variation may be due to differences in population density[21]. The fact that manipulation of relative male parental investment[10] controls sexual differences also argues against the contention that increased male parental investment results from decreased competition between males[19], rather than the converse as argued by Williams[4] and Trivers[5].

Variation in relative parental investments thus seems to cause greatly differing patterns of sexual selection in brief spans of ecological time. Variation in resource availability is likely to determine the relative importance of the male contribution in any species in which females or offspring receive food from the mate. Such paternal investment occurs in a variety of taxa, and includes the donation of prey in birds, and of prey and a variety of male-produced secretions in insects[22]. Therefore, the facultative nature of the courtship roles is unlikely to be unique to spermatophore-consuming katydids. □

Cortical microstimulation influences perceptual judgements of motion direction

C. Daniel Salzman, Kenneth H. Britten & William T. Newsome*

Department of Neurobiology, Stanford University School of Medicine, Stanford, California 94305, USA

NEURONS in the visual cortex respond selectively to perceptually salient features of the visual scene, such as the direction and speed of moving objects, the orientation of local contours, or the colour or relative depth of a visual pattern. It is commonly assumed that the brain constructs its percept of the visual scene from information encoded in the selective responses of such neurons. We have now tested this hypothesis directly by measuring the effect on psychophysical performance of modifying the firing rates of physiologically characterized neurons. We required rhesus monkeys to report the direction of motion in a visual display while we electrically stimulated clusters of directionally selective neurons in the middle temporal visual area (MT, or V5), an extrastriate area that plays a prominent role in the analysis of visual motion information[1–8]. Microstimulation biased the animals' judgements towards the direction of motion encoded by the stimulated neurons. This result indicates that physiological properties measured at the neuronal level can be causally related to a specific aspect of perceptual performance.

Like other cortical sensory areas, MT is organized in a columnar fashion so that clusters of neighbouring neurons have similar physiological properties[9]. In MT, neurons in a single cortical column discharge a burst of action potentials in response to motion in a 'preferred' direction, but yield little or no response to motion in the opposite or 'null' direction. The preferred direction of motion varies systematically from column to column so that MT contains a complete representation of motion direction at each location in the visual field. Consequently, a microstimulation current that selectively elevates the discharge rate of a small cluster of MT neurons should enhance the intracortical signal related to a particular direction of motion. In primate motor cortex, a 10-μA pulse of cathodal current directly activates neurons within ~85 μm of the electrode tip[10]. To activate local clusters of MT neurons, we therefore applied 10 μA stimulating pulses (0.2-msec pulses, 200 Hz, biphasic) to selected sites in which neurons encountered over 150 μm of electrode travel had similar preferred directions. Although we attempted to confine direct excitation to a local cluster, neurons remote from the stimulation site were probably activated trans-synaptically[11]. But activation of remote neurons does not necessarily imply a loss of functional selectivity; there is increasing evidence that cortical columns are preferentially connected with other columns having similar response properties[12,13]. These considerations suggest that microstimulation in our experiments may have activated a circuit of neurons encoding a particular direction of motion.

Our methods for electrophysiological recording and for monitoring eye movements in trained rhesus monkeys were adapted from those of Wurtz and colleagues[14,15], and our psychophysical methods were based on those described by Newsome and Paré[6]. Figure 1 illustrates the procedures used in the present experiments. In brief, three rhesus monkeys were trained to discriminate the direction of motion in a random dot display shown on a video screen. In the display, a specifiable percentage of the dots carried a constant-velocity or 'correlated' motion signal while the remaining dots moved in random directions, creating a masking motion noise. We varied the strength of the motion signal by changing the percentage of dots in correlated motion. For each experiment a new stimulation site was selected and the motion display was placed in the multineuron receptive field mapped at the stimulation site. On a given trial the monkey maintained visual fixation on a stationary point of light while viewing the random dot stimulus for one second. The correlated motion signal was randomly selected to be in either the preferred or null direction of the local cluster of neurons. After the viewing interval, the monkey indicated its judgement of motion direction by making a saccadic eye movement to one of two light-emitting diodes corresponding to the possible directions of the motion stimulus. The monkey received a liquid reward for a correct choice. An experiment consisted of 640 randomly interleaved trials. On half of the trials we applied electrical stimulation that began and ended simultaneously with the onset and offset of the random dot stimulus. The monkeys performed trials at four correlation levels—0% correlation and three levels near psychophysical threshold. The reward contingencies were identical on stimulated and nonstimulated trials.

If microstimulation enhances the intracortical signal related to the preferred direction of motion of the local cluster of neurons, we would expect stimulation to bias the animal's psychophysical judgements towards that direction. Figure 2 shows the results of two experiments in which microstimulation had such an effect. For both experiments, the proportion of decisions in favour of the preferred direction ('preferred decisions') is plotted against the strength of the motion signal expressed as the percentage of dots in correlated motion. The closed symbols represent trials with electrical stimulation; open symbols correspond to nonstimulated trials. Positive correlations indicate motion in the preferred direction and negative correlations represent motion in the opposite direction. Comparing performance on stimulated and nonstimulated trials, one can see that at every correlation level the monkey made more preferred decisions when electrical stimulation accompanied the visual stimulus, with a net increase of 43 preferred decisions in Fig. 2*a* and 118 preferred decisions in Fig. 2*b*.

In both experiments of Fig. 2, the increase in preferred decisions due to microstimulation can be described as a leftward shift of the psychometric function. The magnitude of the leftward shift quantifies the microstimulation effect in units of the visual stimulus. In other words, the magnitude of the leftward shift, expressed as percentage of correlated dots, corresponds to the visual stimulus change that would mimic the behavioural effect of microstimulation. We employed logistic regression analysis[16] to measure the magnitude and statistical significance of the stimulation-induced shift of the psychometric function. For the experiment of Fig. 2*a*, the effect of microstimulation was behaviourally equivalent to the addition of 7.7% correlated dots to the visual stimulus and was highly significant ($P \leq 0.0001$). For the much larger effect in Fig. 2*b*, the effect of microstimulation was behaviourally equivalent to the addition of 20.1% correlated dots ($P \leq 0.0001$).

Microstimulation caused statistically significant shifts in the psychometric function ($P < 0.05$) in 18 of 38 experiments in one monkey, in 9 of 16 experiments in a second monkey, and in 3 of 8 in a third. Figure 3 shows for each experiment the magnitude of the stimulation-induced shift expressed as percentage of correlated dots. Positive values correspond to leftward shifts in the psychometric function and negative values correspond to rightward shifts. Striped bars indicate experiments in which the shift of the psychometric function was statistically significant. In 29 of the 30 experiments that yielded significant effects, microstimulation shifted the psychometric function leftwards, indicating an increase in preferred decisions. In the remaining experiment, microstimulation caused a highly significant rightward shift, an observation that could be explained if microstimulation had a large effect on nearby columns whose preferred direction was opposite to that of the target column. This is a plausible explanation for the single counterintuitive result as adjacent columns of MT neurons sometimes have opposite preferred directions[9].

The data in Fig. 3 show that microstimulation biased the monkeys' perceptual decisions towards the preferred direction of the stimulated neurons. The result is consistent with the notion that focal microstimulation enhances the sensory representation of one direction of motion relative to others. An alternative

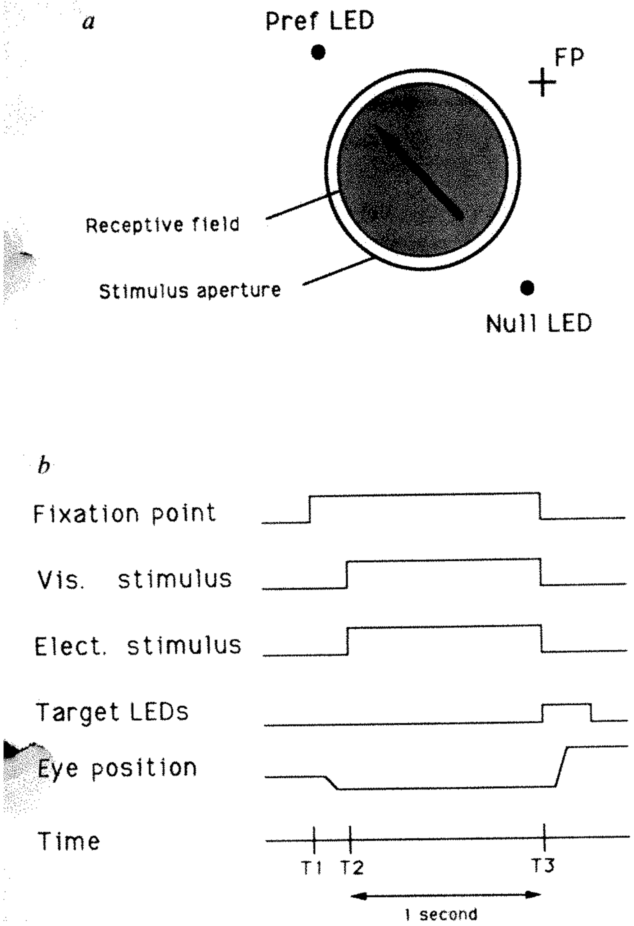

FIG. 1 The experimental protocol used to measure the effect of microstimulation on perceptual judgements of motion direction. *a*, Schematic diagram showing the spatial arrangement of the fixation point (FP), receptive field (shaded), stimulus aperture (thick circle) and response light emitting diodes (LEDs). While the monkey centred its gaze on the fixation point, we mapped the receptive field and identified the preferred direction (arrow) and speed of motion of neurons at the stimulation site. The random dot motion display was presented within a circular aperture whose dimensions and location were matched to those of the multi-neuron receptive field, and the speed of the motion signal was set equal to the preferred speed of the neurons. On a given trial, the motion signal in the visual display was randomly selected to be in the neurons' preferred direction (arrow) or in the null direction (opposite to arrow). The strength of the motion signal was randomly varied among four possible correlation levels: 0% correlation or one of three levels near psychophysical threshold. The monkey viewed the visual display for one second while maintaining its gaze on the fixation point. After the viewing interval, the monkey indicated its choice of motion direction by making a saccadic eye movement to one of two light emitting diodes (Pref LED and Null LED) that corresponded to the two possible directions of motion. Note that in all respects the visual display was tailored so that the demands of the psychophysical task were well matched to the information supplied by the neurons at the stimulation site. Since we tailored the visual display in this manner at each stimulation site, the spatial arrangement of the receptive field, stimulus aperture, preferred–null axis of motion, and response LEDs varied considerably from site to site. *b*, Schematic drawing illustrating the temporal sequence of events during a microstimulation trial. At time T1 the fixation point appeared and the monkey transferred its gaze to the fixation point, as indicated by the deflection in the eye position trace. At time T2 the visual (Vis.) stimulus appeared and the train of electrical (Elect.) stimulation pulses began. The monkey was required to maintain fixation for one second until time T3; if the monkey broke fixation during this interval the trial was aborted. The fixation point, visual stimulus and microstimulation pulses were turned off at time T3, and the target LEDs turned on. The monkey then indicated its judgement of motion direction by making a saccadic eye movement to one of the two response LEDs. A liquid reward was given for a correct choice, and an incorrect choice was penalized with a brief 'time-out' period. Unstimulated trials differed only in that no electrical stimulation accompanied the visual stimulus. The reward contingencies were identical for trials with and without stimulation.

explanation, however, is that microstimulation had a direct effect on the operant response, a saccadic eye movement. The latter hypothesis seems unlikely for several reasons. First, physiological recordings made during saccadic eye movements have failed to find any evidence of motor signals in MT[17]. Second, lesions of MT have no effect on saccades to stationary targets[18]. Third, control experiments show that microstimulation applied during the intertrial interval has no effect on eye movements. Finally, the long latency (>1 s) between the onset of microstimulation and execution of the saccade argues against a direct effect of stimulating current on motor signals. We therefore consider it highly probable that microstimulation affected the sensory signals underlying perceptual judgements of motion direction rather than motor signals related to the saccadic eye movement *per se*.

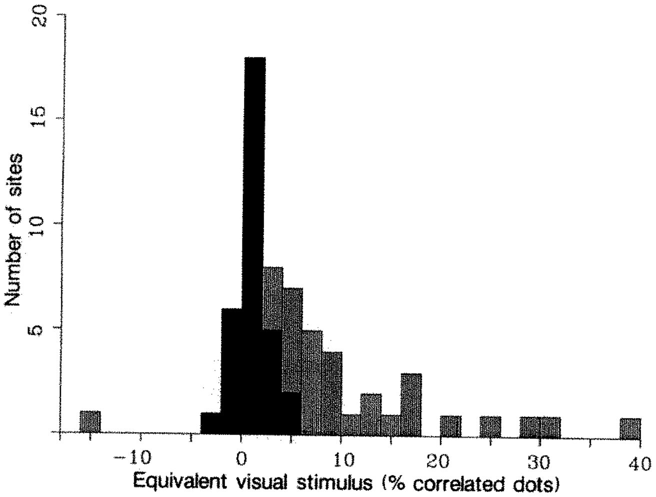

FIG. 2 Effect of microstimulation on psychophysical performance for two stimulation sites in MT. The abscissa indicates the strength of the motion signal in percentage of correlated dots. Positive correlation values indicate motion in the neurons' preferred direction; negative values correspond to motion in the opposite—'null'—direction. The ordinate shows the proportion of trials in which the monkey judged motion to be in the preferred direction of the stimulated neurons (preferred decision). Each data point is based on 40 trials, except for 0% correlation for which 80 trials were conducted. The correlation levels were selected so that the monkey would judge the direction of motion correctly in $\sim$70% of the trials in a block. In half the trials (●) microstimulation was applied simultaneously with the visual stimulus; the other trials (○) contained no microstimulation. For each experiment we employed logistic regression analysis[16] to fit sigmoidal curves of equal slope to the stimulated and nonstimulated data; the curves thus derived provided an acceptable fit to most of the data. *a*, Typical experiment in which stimulation biased the monkey's perceptual decisions towards the preferred direction of the stimulated neurons. The psychometric function for the stimulated trials was shifted leftwards by 7.7% correlated dots. The magnitude of the shift indicates that the behavioural effect of microstimulation could have been reproduced by adding to the visual stimulus 7.7% correlated dots in the preferred direction. *b*, Experiment in which microstimulation induced a leftward shift of 20.1% correlated dots, one of the larger effects we observed. The different appearance of the 'no stimulation' curves in *a* and *b* resulted largely from differences in choice bias in the two experiments. In the no stimulation condition in *a*, the monkey favoured the preferred direction on 56% of the trials at 0% correlation. Note that with no choice bias, the monkey would have made 50% preferred decisions at 0% correlation; in this experiment, therefore, the monkey had a very small choice bias. In the no stimulation condition in *b*, however, the monkey made preferred decisions on only 33% of the trials at 0% correlation. In this experiment, the monkey had a pronounced bias towards the null direction response LED; the effects of this bias are evident at other points on the no stimulation curve as well. Choice bias is a common phenomenon in human and animal psychophysics, and its presence and intensity in any particular experiment is difficult to predict. Most bias values observed in the present experiments were within the range observed in previous experiments that did not involve electrical microstimulation.

As the multi-unit receptive field at a given microstimulation site occupies a small portion of the visual field, it is desirable to know whether the perceptual effects of microstimulation are similarly localized in visual space. To answer this question, we required a monkey to perform the psychophysical task in the usual manner, but applied microstimulation to a topographically noncorresponding site in MT. In these experiments there was no overlap betwen the visual display aperture and the receptive field at the stimulation site. The effect of microstimulation was greatly attenuated or eliminated under these conditions. Thus the microstimulation effects were correlated with the spatial location, as well as the preferred direction, of the receptive field of the stimulated neurons.

Given the complexity of primate visual cortex, which contains more than 20 different visual areas with multiple anatomical interconnections, it is remarkable that local microstimulation of directionally selective neurons can cause a substantial change in psychophysical performance. This result may be less surprising if, as we suggested above, microstimulation trans-synaptically activates an extended circuit of neurons. This amplification of neuronal signals could be accomplished by activation of nearby columns in MT having a similar preferred direction and receptive field location, or by activation of similarly tuned neurons in visual areas other than MT. Although we do not know the full extent of cortex affected by microstimulation, the demonstrated correlation between neuronal preferred direction and psychophysical choice suggests that the activated neurons were functionally related to a particular direction of motion. The data therefore provide evidence causally relating neuronal activity to perceptually judged direction of motion. This experimental approach, which combines electrical microstimulation with multi-neuron physiological analysis and an appropriate perceptual task, may also prove useful for investigating cortical

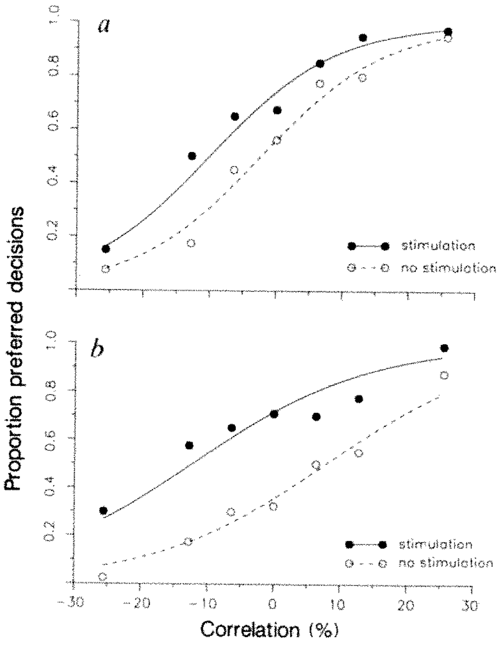

FIG. 3 Frequency histogram showing the magnitude of the stimulation-induced shift in the psychometric function for 62 experiments in three monkeys. The shift in the psychometric function may be thought of as an 'equivalent visual stimulus'—the visual stimulus change that would mimic the behavioural effect of microstimulation. Positive values indicate leftward shifts of the psychometric function; negative values indicate rightward shifts. The striped bars identify experiments in which the effect of microstimulation was statistically significant (logistic regression $P<0.05$). In 29 of the 30 experiments with statistically significant effects, the stimulation-induced shift was leftwards, indicating an increase in decisions favouring the preferred direction of the stimulated neurons.

circuits that contribute to other aspects of visual perception such as orientation, colour and depth. ☐

Presynaptic enhancement shown by whole-cell recordings of long-term potentiation in hippocampal slices

Roberto Malinow* & Richard W. Tsien

Department of Molecular and Cellular Physiology, Beckman Center,
Stanford University Medical Center, Stanford, California 94305, USA

LONG-TERM potentiation (LTP) of synaptic transmission in the hippocampus is a widely studied model system for understanding the cellular mechanisms of memory[1–6]. In region CA1, LTP is triggered postsynaptically[7–10] by Ca^{2+}-dependent[11,12] activation of protein kinases[13,14], but the locus of persistent modification remains controversial[15–25]. Statistical analysis of synaptic variability has been proposed as a means of settling this debate[3,26], although a major obstacle has been the poor signal-to-noise ratio of conventional intracellular recordings. We have applied the whole-cell voltage clamp technique[27] to study synaptic transmission in conventional hippocampal slices (compare refs 28–30). Here we report that robust LTP can be recorded with much improved signal resolution and biochemical access to the postsynaptic cell. Prolonged dialysis of the postsynaptic cell blocks the triggering of LTP, with no effect on expression of LTP. The improved signal resolution unmasks a large trial-to-trial variability, reflecting the probabilistic nature of transmitter release[31–35]. Changes in the synaptic variability, and a decrease in the proportion of synaptic failures during LTP, suggest that transmitter release is significantly enhanced.

We made whole-cell voltage clamp recordings[27–30] from CA1 neurons in rat hippocampal slices (400–500 μm). Positive pressure was applied to the recording pipette during penetration of the slice; high-resistance (1-5 GΩ) seals on cell bodies 2-3 cell diameters below the surface were then obtained by suction. After breaking into the cell, synaptic currents were elicited with bipolar stimulation electrodes placed in the stratum radiatum of CA1. Stable synaptic recordings could be maintained for as long as 10 hours.

To optimize the chances of obtaining LTP under whole-cell recording conditions, we used internal solutions with minimal Ca^{2+} buffering to avoid block of LTP[11,12], and with Cs^{+} as the main cation to enhance voltage control of the postsynaptic membrane. We also included ATP and GTP in the internal solution to allow activity of protein kinases or GTP-binding proteins. After a stable baseline period of 10–15 min, we were able to induce LTP by pairing[7,9,10] a steady postsynaptic depolarization to ~0 mV with continued activation of the test pathway (40 stimuli at 2 Hz). This pairing procedure resulted in LTP in 14 out of 18 experiments (Figs 1*c*, 3*a* and 4*c*). By contrast, no potentiation was found in transmission through a simultaneously monitored control pathway that did not receive presynaptic stimuli during the postsynaptic depolarization (Figs 1*d*, 3*b*). Furthermore, synaptic stimulation at 2 Hz without postsynaptic depolarization did not give synaptic enhancement ($n = 5$). Thus, the potentiation was synapse-specific and required a combination of presynaptic activity and postsynaptic depolarization, just as seen in conventional recordings of LTP[1–6,36].

To investigate whether diffusible cytoplasmic factors are involved in potentiation, we attempted to trigger LTP at different times after gaining whole-cell access (Fig. 1*c*, *d*). Pairing soon after starting whole-cell recording (~20 min or less) consistently resulted in LTP lasting >1 hour (Figs 1, 3 and 4). But no potentiation was found with pairing >30 min after whole-cell access (6 out of 7 experiments). One possibility is that some diffusible postsynaptic substance is needed to trigger LTP, but not to maintain the potentiation.

The low background noise of whole-cell recordings allowed us to study small responses evoked with minimal stimulation, only slightly stronger than the highest stimulus that gave all failures. With minimal stimulation, activation is thought to be restricted to a single synapse onto the monitored neuron[25,37]. The resulting synaptic currents showed a large variability between trials that was much greater than the background noise, but their individual time courses were similar (Fig. 1*a*, *b*), supporting the view that they originated from the same synapse[25,37]. There were occasional clear failures (Figs 1*a* and 4*a*, *b*), and sporadic spontaneous events that resembled the elicited response, ranging in amplitude from <1 pA to ~10 pA (Fig. 1*b*, inset).

To understand the basis of the synaptic variability and its possible relation to fluctuations in transmitter release, we modified presynaptic or postsynaptic functions by changing the bathing medium (Fig. 2). Raising the extracellular calcium concentration ($[\mathrm{Ca}^{2+}]_0$) to increase presynaptic release[38] enhanced the synaptic currents (Fig. 2*a*), and changed their amplitude histogram from a highly skewed distribution (Fig. 2*b*) to a nearly symmetrical bell-shape (Fig. 2*c*). By contrast, when we added low concentrations of the glutamate receptor antagonist 6-cyano-7-nitroquinoxaline-2,3-dione[39] (CNQX) to modify postsynaptic responsiveness, the average synaptic current was dramatically reduced, but the shape of the distribution remained unchanged (Fig. 2*a*, *e*). The distributions before and after CNQX therefore matched closely when normalized by their means (Fig. 2*d*). We obtained similar results with CNQX at lower $[\mathrm{Ca}^{2+}]_0$ (data not shown).

To derive a simple and revealing index of synaptic variability, we computed $V^{-2} = M^2/\sigma^2$, where V is the coefficient of variation, M is the mean synaptic current and σ^2 is the variance about M, for a given epoch of consecutive responses from t to $t+\tau$. We can compute the expected behaviour of M^2/σ^2 if we make assumptions about the mechanisms underlying synaptic transmission. In the simplified case of a binomial distribution of transmitter release, $M^2/\sigma^2 = (Npvz)^2/Np(1-p)(vz)^2 = Np/(1-p)$, where p is the probability of release for each of N available quanta, v is the vesicular content, and z is the postsynaptic response to a fixed amount of transmitter. Thus, M^2/σ^2 is independent of changes in z and is a useful measure of some changes in presynaptic function, but not all factors (for example,

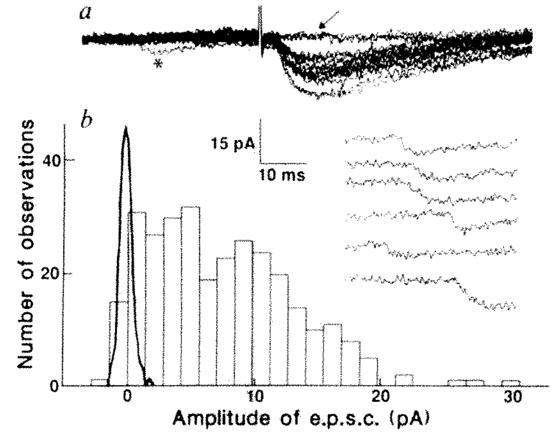
v). It increases in proportion to N, and at least linearly with p, as experimentally confirmed at the neuromuscular junction[31]. The lack of dependence of M^2/σ^2 on the postsynaptic responsiveness (z) holds for more general cases as long as z does not vary from trial to trial within a given epoch (see Fig. 2 legend).

Assuming z is constant for an epoch, the theory predicts that changes in M^2/σ^2 between epochs will result from changes in release characteristics but not postsynaptic modifications. This was tested by examining changes in M^2/σ^2 following interventions known to affect presynaptic or postsynaptic mechanisms. As Fig. 2e illustrates, raising extracellular calcium dramatically increased M^2/σ^2. This was found for all experimental manoeuvres expected to affect presynaptic release: lowering magnesium, application of 4-aminopyridine (data not shown) or increasing the stimulus strength to recruit more afferent fibres (Fig. 2f; $n = 10$). In general, M^2/σ^2 increased at least as much as the mean synaptic current. By contrast, addition of CNQX produced no significant change in M^2/σ^2, despite its large effect on synaptic transmission ($n = 5$; see Fig. 2e, g).

Does M^2/σ^2 change with LTP? Figure 3b compares M^2/σ^2 of the test pathway with that of the control (unpaired) pathway, for the 14 experiments showing potentiation of mean synaptic current (Fig. 3a). Following pairing, M^2/σ^2 increased significantly in the test pathway, with no change in the control pathway. The increase in M^2/σ^2 with LTP could arise from various presynaptic mechanisms: an increase in the number o available vesicles; an increase in the probability of release o some or all vesicles; a non-uniform increase in the amount o transmitter in the vesicles; or changes in non-vesicular release It would not be expected from uniform changes in the number sensitivity or conductance of glutamate receptor channels, or if the effectiveness of charge transfer from spines to dendrites.

If the expression of LTP involves an increased probability o release or a greater number of available quanta, one would expect fewer failures of transmission during LTP. Figure 4 illustrates an experiment where failures and responses were clearly resolvable. The amplitude distribution histogram had a distinct peak at zero amplitude which matched the amplitude distribution of the noise (inset). The area under the 0 pA peak was used to estimate the percentage of failures. In this experiment, the proportion of failures decreased from 27% in control to 11% during LTP. This decrease was a consistent finding in each of five experiments where failures could be clearly resolved ($n = 3$ with minimal stimulation and $n = 2$ with intracellular microelectrode stimulation of a CA3 neuron). The collected data from all five experiments showed a mean (±s.e.m.) decrease in failures from 63 ± 11% in control, to 17 ± 8% after pairing consistent with a greater likelihood of transmitter release during



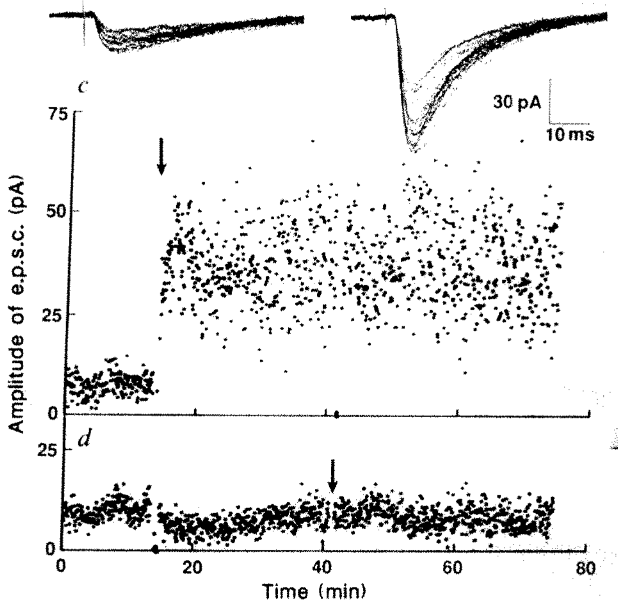


FIG. 1 Whole-cell recordings of synaptic transmission in conventional hippocampal slices show large inter-trial variability, synapse-specific LTP, and loss of induction but not expression, with prolonged dialysis. a, Sixteen consecutive records of excitatory postsynaptic currents (e.p.s.cs), superimposed. Note spontaneous event in baseline period (asterisk) and synaptic failures (arrow). b, Amplitude distribution histograms for 200 consecutive synaptic currents (bars) and baseline noise (smooth curve). Bin sizes were 1.4 pA for e.p.s.c., and 0.14 pA for baseline noise. Inset: Representative spontaneous synaptic currents. Note the variability in amplitude and time course but an otherwise general similarity to evoked responses. c, d, Plots of synaptic responses against time in a postsynaptic cell receiving two independent inputs. c, LTP was selectively induced in one pathway by a pairing procedure 15 min after break-in (arrow); in the other pathway (d), the pairing procedure was applied 25 min later, but failed to induce LTP, in contrast to the maintenance of LTP in c. In the pairing procedure, the cell was depolarized from −70 mV to ~0 mV, while the paired (conditioned) pathway was stimulated 40 times at 2 Hz with no change in stimulus strength. Non-conditioned pathway received no stimuli during the postsynaptic depolarization. Inset: Families of consecutive current records showing e.p.s.cs of conditioned pathway, collected before (left) and 30 min after pairing (right).

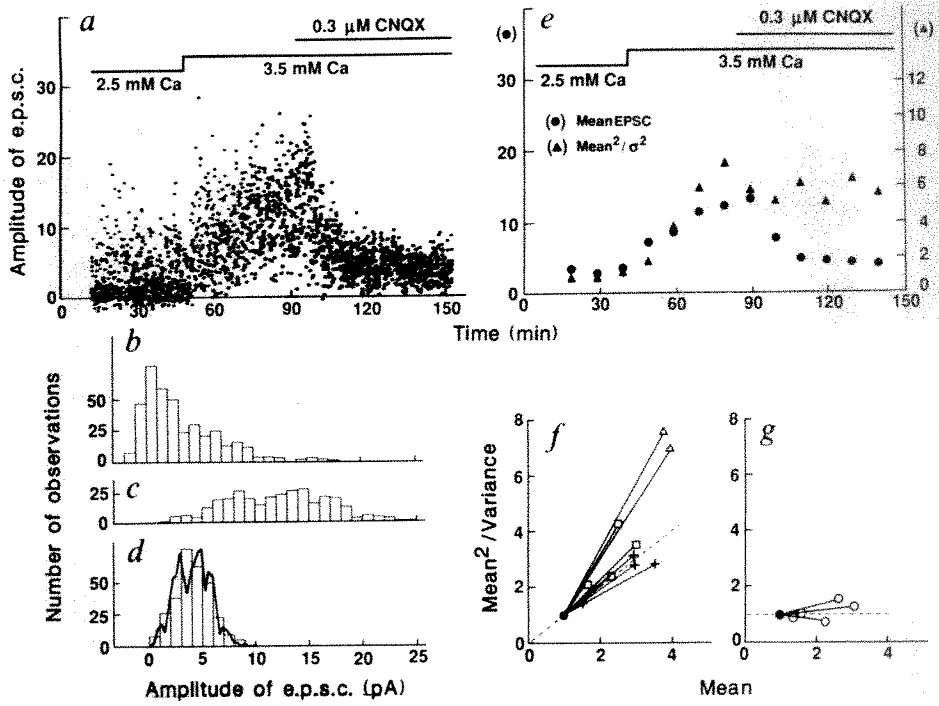
METHODS. Transverse hippocampal slices (400–500 μm), obtained from 3–5-week-old rats by standard methods[42], were submerged and superfused continuously with a modified Earle's solution containing (in mM): NaCl, 119; KCl, 2.5; $MgCl_2$, 1.3; $CaCl_2$, 2.5; NaH_2PO_4, 1.0; $NaHCO_3$, 26.2; glucose, 11; picrotoxin, 0.02, and gassed with 95% O_2/5% CO_2 (pH 7.4) at room temperature (22 °C). A cut was made between regions CA3 and CA1 to prevent epileptiform activity. Synaptic transmission was elicited with bipolar stainless steel stimulating electrodes at two locations; each electrode delivered a stimulus every 4 s; stimuli from the two electrodes were separated by 2 s. E.p.s.cs were recorded with a patch electrode (3–7 MΩ tip resistance, no fire polishing or Sylgard coating) in the whole-cell mode (Axopatch 1D). Pipette solution contained (in mM): Caesium gluconate, 100; EGTA, 0.6; $MgCl_2$, 5; ATP, 2; GTP, 0.3; HEPES, 40 (pH 7.2 with CsOH). Holding potential was kept constant at a level between −60 and −70 mV. E.p.s.cs were amplified 50–500 fold, filtered at 1 kHz, digitized at 10 kHz and stored. For a given experiment, e.p.s.c. amplitudes were determined by averaging the current over a 10–20 ms window at the peak response and subtracting a baseline estimate from the same record. A similar procedure was used to measure the background noise before the synaptic stimulation[34]. In a representative series of 17 experiments, the average synaptic current for minimal stimulation was 6.7 pA, in reasonable agreement with estimates of synaptic current from minimal e.p.s.ps recorded with high-resistance microelectrodes[25,34], after allowing for input resistance. Note, however, that the background noise in whole-cell recordings was considerably lower than in the most favourable microelectrode recordings[25,34]. The input resistance in whole-cell recordings was typically 100–200 MΩ.

TP. This conclusion is supported by the overall amplitude istribution, which changes from a skewed shape in control Fig. 4*d*) to a bell-shape during LTP (Fig. 4*e*), as with increasing xtracellular calcium (Fig. 2*b*, *c*).

One of our main findings is that whole-cell recordings can be sed to study synaptic transmission over many hours in neurons that are well below the surface of conventional brain slices (see also ref. 29). This approach is an alternative to methods that require cleaning of the surface of slices[30], and it allows access to deeper cells that are more likely to retain intact dendritic structures and functional properties.

Our experiments show that synapses can display LTP even



IG. 2 Agents acting through presynaptic nechanisms affect shape of distribution istograms and M^2/σ^2, whereas inhibition f postsynaptic receptors does not. *a*, .p.s.c. amplitude plotted against time. athing calcium was raised from 2.5 mM o 3.5 mM, and 0.3 μM CNQX was applied vhere shown. *b*–*d*, Amplitude distribution istograms for 300 e.p.s.cs before nanipulation (*b*), after elevation of calcium *c*), and after subsequent addition of CNQX *d*). Continuous line in *d* shows data from *c*, normalized to mean e.p.s.c. amplitude in *d*. Note close agreement of normalized histograms. *e*, Plot of mean e.p.s.c. amplitude, *M* (circles) and M^2/σ^2 (triangles) for the experiment shown in *a*, with $\tau=10$ min (150 trials). *f*, Plot of M^2/σ^2 against *M* for several presynaptic manipulations: concentration of calcium was increased from 2.5 to 3.5 mM (triangles); magnesium was decreased from 1.3 to 0.65 mM in the presence of 50 μM 5-aminophosphonovaleric acid (squares); increased stimulus strength to recruit more fibres (cross). *g*, Plot of M^2/σ^2 against *M* for experiments in which CNQX (0.2–0.3 μM) was applied to the bath. For each experiment in *f* and *g*, lines connect points obtained before and after manipulation; *M* and M^2/σ^2 were computed for 300 trials before the manipulation and for 300 trials at the peak of the effect, and normalized by the values corresponding to the smaller *M* for that experiment. Note that presynaptic manipulations thought to increase *p* affect M^2/σ^2 more than the mean, whereas increasing stimulus strength, which increases *N*, affects M^2/σ^2 as much as *M*. These findings are expected for a binomial release process (see text). Postsynaptic receptor blockade generally had no affect on M^2/σ^2. This conforms with predictions of a treatment of synaptic responses that does not presuppose binomial statistics, uniformly sized packets, or even vesicular release. In the general case, the release process is considered to behave as a probability density function $R(x)$, where x is allowed to vary over possible values of transmitter release. The postsynaptic response is assumed to be zx, where z is a constant postsynaptic response factor. From the elementary probability theory, the mean synaptic response is given by $\langle zx\rangle$ and the variance about the mean is $\langle(zx-\langle zx\rangle)^2\rangle$, where $\langle\ \rangle$ denotes the expectation for trials within the epoch τ. Then $M^2/\sigma^2=\langle zx\rangle^2/\langle(zx-\langle zx\rangle)^2\rangle=z^2\langle x\rangle^2/(\langle(zx)^2\rangle-\langle zx\rangle^2)=z^2\langle x\rangle^2/z^2(\langle x^2\rangle-\langle x\rangle^2)=\langle x\rangle^2/(\langle x^2\rangle-\langle x\rangle^2)$. Thus M^2/σ^2 depends only on characteristics of the release process for that epoch, and not on z. This formalism assumes that postsynaptic responsivity is linear and does not vary from trial to trial (that is, z is constant) within the epoch τ, as found at the neuromuscular junction[31,32]. It ignores the possibility of rapid and concerted changes in the receptivity of ensembles of receptors or a spatial heterogeneity in receptivity that responds differentially to independent sites of transmitter release.

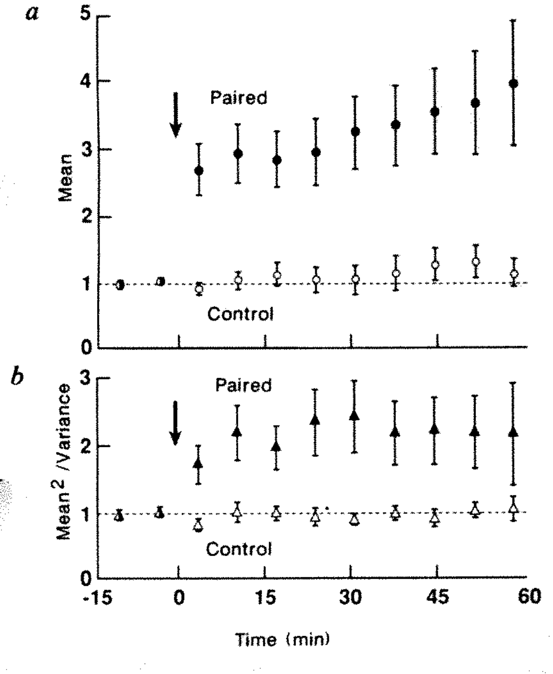


FIG. 3 A synapse-specific increase in M^2/σ^2 associated with LTP. Results from the 14 of 18 experiments that showed LTP with pairing (in the other four experiments with no LTP, M^2/σ^2 remained unchanged; data not shown). *a*, Ensemble averages and s.e.ms of *M* for the paired pathway (filled circles) and the control pathway (open circles, $n=10$; in 4 experiments this pathway was not monitored). Arrow marks time of pairing procedure (as in Figs 1, 2). *b*, Ensemble averages of M^2/σ^2 for paired (filled triangles) and non-paired (open triangles) pathways for the same experiments as in *a*. Note that *M* increased more than M^2/σ^2, particularly 30–60 min after pairing; the late change in *M* may reflect a delayed increase in postsynaptic responsivity[24].

after the postsynaptic cell has been accessed by a whole-cell recording pipette. This opens up the possibility of probing the postsynaptic mechanisms of LTP with a wide range of biochemical compounds, such as large proteins or nucleic acids, that could not be reliably delivered with intracellular microelectrodes. It is interesting that the ability to undergo LTP was lost after longer periods of whole-cell recording, as if some key cytoplasmic constituent were washed out, even though LTP established earlier during the recording did not decay. This contrast supports the idea that induction and persistence of LTP involve different molecular events, possibly in different locations[13,40,41].

Another advantage of whole-cell recordings is that they give much better signal-to-noise than conventional intracellular recordings, facilitating statistical analysis of small synaptic signals. Experiments conform with theory in supporting M^2/σ^2 as a simple measure of changes in presynaptic function. In principle, this approach could be useful in characterizing neuroactive drugs whose locus of action is unknown.

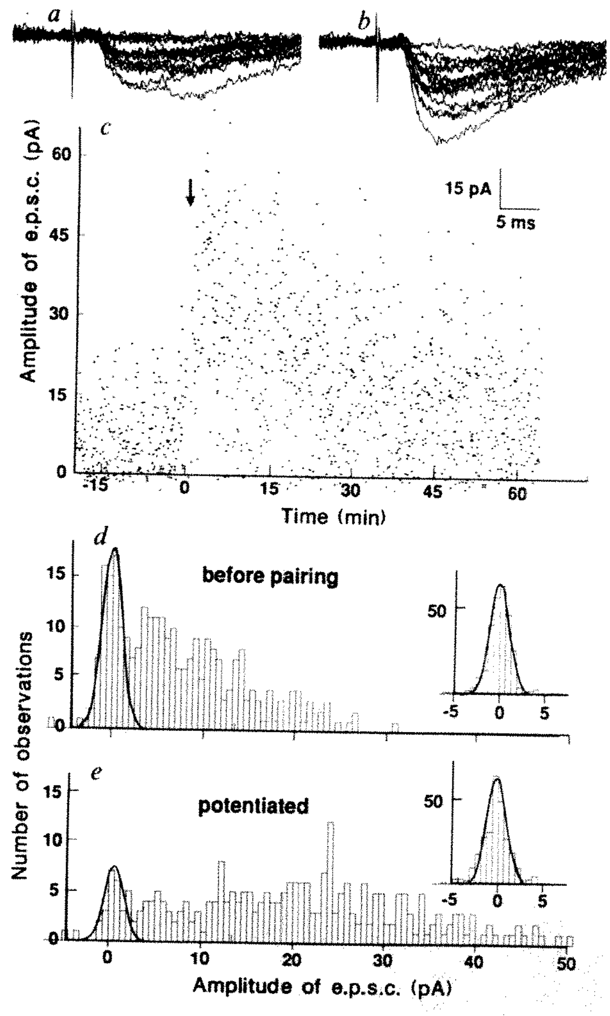

FIG. 4 Decreases in the proportion of synaptic failures associated with LTP. *a*, *b*, Groups of 16 consecutive e.p.s.cs taken before (*a*) and 40 min after (*b*) a pairing procedure to induce LTP. *c*, Amplitude of e.p.s.cs elicited by minimal stimulation plotted against time. Arrow marks pairing procedure (see Fig. 1). *d*, *e*, Amplitude distribution histograms for 17 min epochs before pairing (*d*, from $t=-17$ to $t=0$) and after pairing (*e*, from $t=5$ to $t=22$ min). Smooth curves are gaussians whose height was adjusted to fit the first peak in the amplitude distribution. The half-width of the gaussians, 2.5 pA, was obtained by fitting amplitude histograms of the baseline noise during the same epochs (insets). The proportion of failures, estimated as the area under the gaussian curve, was 27% before pairing (*d*), and 11% between 5 and 22 min after pairing (*e*). Note the change in shape of amplitude distribution histogram in association with 2.8-fold increase in mean synaptic current from *d* to *e*. During a later epoch (from $t=40$ to $t=57$ min, histogram not shown), the synaptic enhancement was 2.1-fold relative to control, and the proportion of failures was 15%.

Our results provide electrophysiological evidence for changes in presynaptic function during LTP, as already suggested[13,15-19]. This conclusion is based on two independent but complementary approaches. The analysis of M^2/σ^2 is relatively model-independent, and does not require failures. M^2/σ^2 increased significantly and remained elevated during LTP; it was unchanged in pathways not undergoing potentiation (Fig. 3*b*). An analysis based on failures gives a more direct view of presynaptic function, but requires unitary events that are large relative to the background noise. In all cases where failures were clearly resolved, their occurrence was greatly diminished during LTP (see Fig. 4*e* for example). Thus, both sets of results support an increase in the likelihood of transmitter release.

Our results do not exclude some change in postsynaptic responsivity (Fig. 3 legend). This possibility[20-22] is supported by a recent report of minimal excitatory postsynaptic potentials (e.p.s.ps) in which no clear change in quantal content was detected in association with a 30% potentiation[25]. The enhancement of transmitter release may have been more pronounced in our experiments because the potentiation was considerably larger (~200%).

Our evidence supporting presynptic changes with LTP is striking in light of previous studies showing that induction is postsynaptic[7-13]. The combination of results makes it difficult to escape the conclusion that a retrograde message must travel from the conditioned postsynaptic cell to modify presynaptic function[1-5]. As the proportion of failures decreases and M^2/σ^2 increases soon after pairing, the retrograde communication must occur promptly. ☐

RETROVIRUSES are involved in several human neurological diseases with varying pathological features[1–3]. Whether these diseases are due to a direct effect of the virus on nervous system cells is unknown. To gain insight into the pathogenesis of one retroviral neurological disease, we are studying the murine neurotropic retrovirus, Cas-Br-E, which causes lower motor neuron disease associated with spongiform degenerative changes in brain and spinal cord[4]. Central nervous system (CNS) injury seems to be due to direct viral action[5], but the precise target cells of the virus are uncertain. After blood-borne virus enters the CNS it is found in capillary endothelial cells[5–7]. No microscopic evidence for virus within glia or neurons has been found in some studies[6], whereas virus or incomplete particles have been observed in CNS cells in other studies[5,8]. Here we identify the neuron as a major target for Cas-Br-E in the CNS, suggesting that this disease may be a direct result of viral infection of neurons. We also show that envelope protein (Env, encoded by the *env* gene), a major determinant of neurovirulence[9,10], cannot be detected in neurons but is present in non-neuronal cells, although spliced *env* messenger RNA is synthesized in CNS tissue. This suggests that a post-transcriptional step in Cas-Br-E Env protein synthesis is impaired and that the neurological disease may be a consequence of abortive replication of virus in neurons. This may explain the failure to find neuronal infection in other neurological diseases by conventional methods of virus detection.

To determine the target cells for Cas-Br-E in the CNS, we compared the virus–host cell interactions of neurovirulent Cas-Br-E with that of non-neurovirulent Moloney murine leukaemia virus (MoMuLV). Whereas postnatal infection of mice with MoMuLV results in viral infection of primarily haematopoetic cells, mid-gestation infection of embryos allows MoMuLV to infect a wide variety of cells[11], including most cell types in the nervous system. Mice expressing even large amounts of virus in the nervous system do not, however, develop neurological disease. Mid-gestation infection with Cas-Br-E produces a disease that is clinically and pathologically the same as neonatal infection, except that its course is markedly shortened[12].

We infected mice intraperitoneally (i.p.) at birth or at mid-gestation. Spongiform degeneration and marked gliosis were observed in the spinal cord, brain stem, cerebellum and subcortical regions, as seen previously[4]. Cells identified morphologically as large motor neurons were stained when spinal cord sections of mice infected with Cas-Br-E i.p. at birth or at mid-gestation were treated with an anti-MoMuLV antibody that detected Cas-Br-E and MoMuLV viral antigens (Fig. 1). Other cells not readily identified under the light microscope also

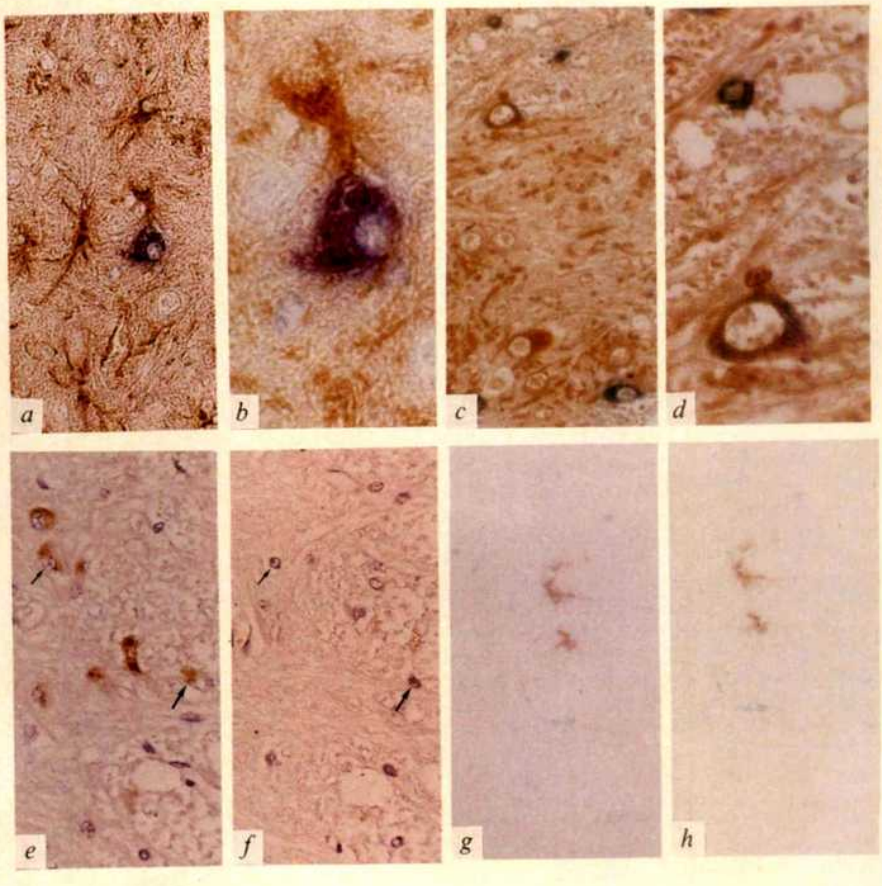

FIG. 1 *a–d*, Double immunohistochemical staining of infected spinal cord sections. Note the colocalization of viral antigens and neurofilament antigens to the same cells. Brown, immunoperoxidase (IMP) staining of glial cells using antibodies to GFAP (*a*, *b*) or neurons using antibodies to neurofilaments (*c*, *d*); purple, alkaline phosphatase (AP) staining of virus-infected cells. *e–h*, Cells visualized by the anti-total virus antiserum were not stained with a polyclonal antibody recognizing gp70 in adjacent sections of Cas-Br-E infected spinal cord. Note lack of reactivity of anti-Env antibody (*f*) as compared with anti-total virus antibody (*e*). Arrows identify identical cells in the adjacent sections. These two antisera gave similar results in MoMuLV-infected tissues (*g*, anti-total virus; *h*, anti-Env). Brown, immunoperoxidase staining of virus-infected cells. Magnification: ×560, *a*, *c*, *e–h*; ×1,400, *b*, *d*. Counterstain in (*e*) and (*f*) is haematoxylin and in *g* and *h* is methyl green.

METHODS. SWR/J mice were infected i.p. as neonates with 0.05 ml virus with a titre of 10^6 XC plaque-forming units per ml or at mid-gestation[7] with approximately 0.05 μl virus of the same titre. Virus was prepared from cells producing cloned MoMuLV or Cas-Br-E (clone NE-8)[17]. Mice infected i.p. with Cas-Br-E were examined from 2 weeks to 5 months post-infection. Mice infected with Cas-Br-E or MoMuLV as mid-gestation embryos were examined at embryonic day 16, postnatal days 14 and 24 and at 2 and 3 months after birth (MoMuLV-infected mice). Four mice were examined at each time point. Mice were anaesthetized with sodium pentabarbital and perfused through the heart, first with 0.9% NaCl containing 100 units heparin per ml (Sigma) and then with Carnoy's fixative, both pre-chilled to 4 °C. Small portions of tissue were then post-fixed in Carnoy's at 4 °C overnight, dehydrated in graded alcohols and xylenes and embedded in paraplast plus. Serial 3-μm sections were cut and heat-baked onto glass slides pretreated with Elmer's glue (Borden). Immunohistochemistry was performed as described[18]. For recognition of viral antigens, slides were incubated with goat antibodies to total virus (NIH 81S107) or to the viral envelope (gift of W. Schäfer) followed by a donkey anti-goat AP conjugate (1:100, Jackson Immunoresearch). Antibody localization was visualized by incubating sections with 1 mg ml^{-1} Fast Blue BB (Sigma), 0.2 mg ml^{-1} napthol AS-MX phosphate in 0.1 M Tris buffer, pH 8.2. For detection of GFAP, sections were incubated with rabbit anti-GFAP antibody (1:800, Accurate), followed by a donkey anti-rabbit IMP conjugate (1:100, Jackson Immunoresearch). For detection of neurofilaments, the avidin-biotin system used mouse anti-neurofilament antibodies (SM32, 1:4000, Sternberger-Meyer) followed by a mouse Vectastain ABC kit (Vector). Antibody localization was visualized using a peroxidase reaction with 3,3′-diaminobenzidine tetrahydrochloride (Aldrich) as the chromagen (1.5 mg ml^{-1}, with 0.1 ml of 3% hydrogen peroxide). Slides were counterstained with methyl green or haematoxylin.

TABLE 1 Cas-Br-E and MoMuLV interactions with cells in the CNS

	Cas-Br-E		MoMuLV	
	Disease	Target cells	Disease	Target cells
Mid-gestation	Paralysis (15–30 days)	Neuron (endothelial, rarely astrocytes)	Leukaemia (3–5 months)	Neuron, glia endothelial
Postnatal	Paralysis (4–6 months)	Neuron (endothelial, rarely astrocytes)	Leukaemia (5–10 months)	None

contained viral antigens. Using antisera against glial fibrillary antigen protein (GFAP) to identify astrocytes, and antisera against neurofilament (NF) subunits to identify neurons, double immunohistochemical staining studies revealed that the vast majority of infected cells were neurons (Fig. 1*a–d*). Infection of astrocytes occurred only rarely, and infection of endothelial cells was seen primarily early after virus exposure. Only a few per cent (at most five) of the infected cells were non-neuronal and non-endothelial. These cells may be oligodendroglia or microglia. Mice infected as mid-gestation embryos with MoMuLV had infected endothelial cells, astrocytes and neurons (Table 1).

Because previous genetic studies had suggested the importance of the *env* gene in the pathogenesis of Cas-Br-E neurological disease[10], tissue sections were also examined with polyclonal antibody reactive against MoMuLV or Cas-Br-E gp70. Unexpectedly, a comparison of immunocytochemical staining of adjacent spinal cord sections prepared from infected Cas-Br-E mice with the anti-Env and anti-total virus sera revealed that the two antisera gave dramatically different results. Neurons visualized by the anti-total virus antibody were not stained in adjacent sections reacted with anti-Env antibody (Fig. 1*e*, *f*), whereas sections of Cas-Br-E-infected spleen and thymus stained similarly with both antisera. Neurons, glia and endothelial cells in mice infected at mid-gestation with MoMuLV were stained with both antisera, as would be expected for a productive virus infection (Fig. 1g, *h*).

To investigate Env protein synthesis in the CNS, western blo analysis was carried out using tissue extracts prepared fron mice infected with Cas-Br-E or MoMuLV and control, uninfected SWR mice. Confirming the results in Fig. 1, no Env protei was detected in the CNS of mice infected with Cas-Br-E, i contrast to mice infected with MoMuLV. (Fig. 2). Viral protein other than Env were present in tissue extracts of Cas-Br-E infected cerebrum, cerebellum, medulla and spinal cord. Th spleen and thymus of Cas-Br-E-infected mice contained all th viral proteins including Env. As expected, all viral protein (including Env) were observed in tissues prepared from mic infected with MoMuLV at mid-gestation and probed with th same antiserum (Fig. 2). An independently prepared polyclona antiserum to Env protein, reactive against both Cas-Br-E an MoMuLV gp70, gave identical results (data not shown). If th Env protein had been present, it should have been detectable as the levels of other viral proteins were comparable in thymu and CNS tissue extracts.

To determine whether the *env* mRNA was present in brai and spinal cord, we examined viral transcription in infecte tissues. Cas-Br-E *env* mRNA was present in CNS tissues (Fig 3) and quantitative analysis of the amount of *env* mRNA i brain and spinal cord compared with other organs revealed n major differences. Thus, a post-transcriptional step in Env synthesis is responsible for aberrant synthesis of Env protein in th CNS.

Our studies identify the neuron as a major target for Cas-Br-E in the CNS, suggesting that spongiform degeneration could be a direct result of viral gene expression in the neuron, rathe than an indirect consequence of viral infection of glia o endothelial cells[7,10]. It was unexpected that a post-mitotic cell would be the main target for Cas-Br-E and in this respect Cas-Br-E resembles the lentiviruses, which replicate in non-dividing macrophages[13,14]. The interaction of Cas-Br-E with neurons, however, differs in important ways from its interaction with other cells. Replication of Cas-Br-E in neurons, but not in non-neuronal cells, is abortive, by contrast with replication of the non-neurotropic MoMuLV which replicates productively in all cells. Abortive infection may explain the failure in previous

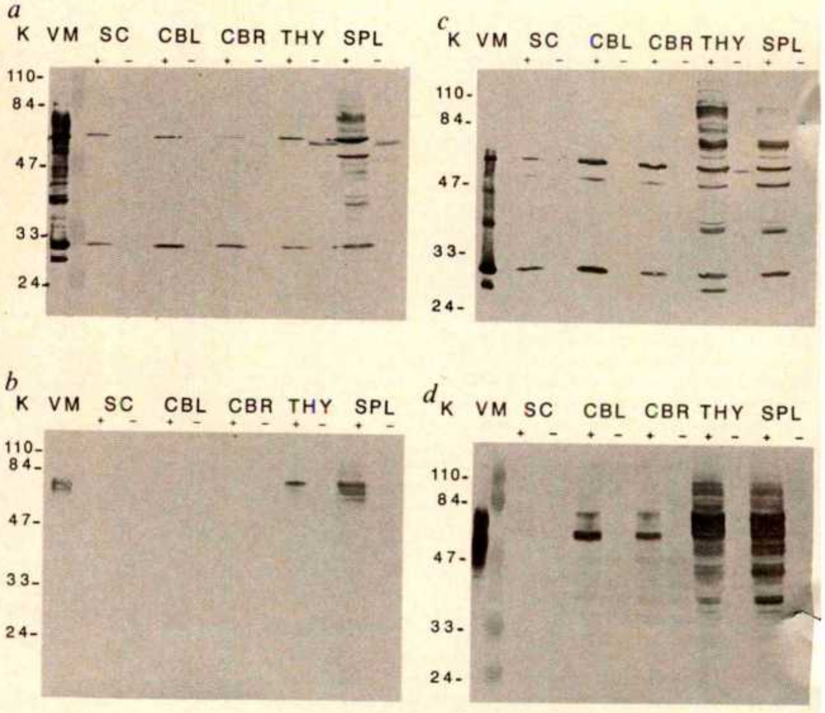

FIG. 2 Western blot analysis of tissue extracts prepared from Cas-Br-E (*a* and *b*) and MoMuLV-infected (*c* and *d*) mice and probed with anti-total virus (*a* and *c*) or anti-Env (*b* and *d*) antisera. Note that Env protein was not detected in Cas-Br-E-infected CNS but was present in other Cas-Br-E infected tissues and in all MoMuLV-infected tissues. Prominent bands with anti-total virus serum correspond to Pr65gag and p30. +, infected tissue; −, uninfected control tissue; sc, spinal cord; cbl, cerebellum; cbr, cerebrum; thy, thymus; spl, spleen; v, purified virus; m, protein relative molecular mass marker.

METHODS. Tissues were teased apart in 4 °C PBS. Cytoplasmic extracts were prepared by resuspending tissue in lysis buffer (1:5, vol cells:vol buffer; 300 mM sucrose, 1 mM EDTA, 1 mM EGTA, 20 mM Tris buffer, pH 8.0, 20 mM HEPES buffer, pH 7.3, 0.4% Nonidet-P40, 50 mM NaCl, 2 mM PMSF, 1 unit ml^{-1} aprotinin, 5 $\mu\mathrm{g\ ml}^{-1}$ chymostatin, 5 $\mu\mathrm{g\ ml}^{-1}$ pepstatin and 5 $\mu\mathrm{g\ ml}^{-1}$ leupeptin) and centrifuging at 400*g* for 5 min. Supernatants were diluted 1:1 in 2× Laemmli sample buffer and frozen at −70 °C. Aliquots (100 μl) of each extract were run on 12.5% polyacrylamide gels and transferred to nitrocellulose[19]. Nitrocellulose membranes were blocked with 5% Carnation milk, probed with goat anti-total virus (NIH81S107) or goat anti-Env (W. Schafer antibody or NIH78S225) antisera diluted in PBS containing 0.3 M NaCl and 0.1% Triton X-100 (Buffer A) for 4 h, washed in Buffer A, then incubated with rabbit anti-goat AP conjugate (Sigma, 1:2,000) for 30 min. Filters were washed with buffer A and developed in 1 mg ml^{-1} nitroblue tetrazolium, 0.5 mg ml^{-1} BCIP in 50 mM diethylamine, pH 9.5 containing 10 mM $\mathrm{MgCl_2}$.

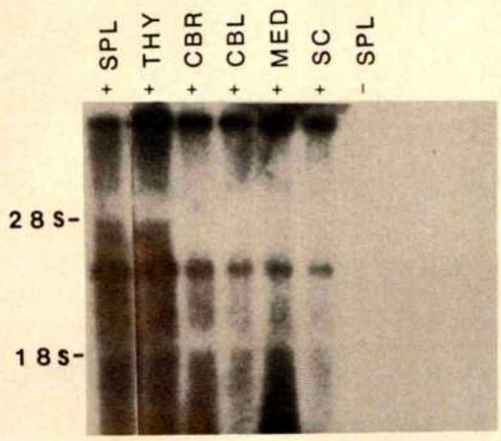

FIG. 3 Northern blot analysis of RNA from Cas-Br-E mice. +, infected tissue; −, uninfected control tissue. Abbreviations as in Fig. 2; med, medulla. The +Spl lane was exposed half as long as other lanes.

METHODS. Total RNA was isolated from tissue obtained from a 3-month-old mouse infected with Cas-Br-E neonatally by acid guanidinium-thiocyanate-phenol-chloroform extraction[20] and separated on 1% agarose, 2.2 M formaldehyde gels. RNA was transferred by capillary blotting onto Gene Screen Plus nylon membranes (NEN). Filters were probed with a Cas-Br-E-sequence-specific probe (*Bam-Taq* fragment of *env*). DNA inserts of plasmid were purified, radiolabelled with ^{32}P by random primer synthesis[21] and hybridized to northern blots at a concentration of 2.5×10^6 c.p.m. ml^{-1}. Hybridizations were carried out at 47 °C in 50% formamide, 5× SSC, 2× Denhardt's and 0.01% yeast transfer RNA. After overnight hybridization, filters were washed twice at 70 °C in 2× SSC, 0.1% SDS, then washed twice in 0.2× SSC, 0.1% SDS at 70 °C, and exposed.

studies to detect mature particles in neurons of infected animals.

Although Cas-Br-E viral Gag and Pol proteins were efficiently translated from viral genomic RNA in all tissues, no Env proteins were detected in brain and spinal cord, although normal amounts of *env* mRNA were synthesized. Although these results indicate that the Cas-Br-E *env* mRNA is present, they do not rule out the possibility that a splicing error not grossly affecting mRNA size has occurred. Alternatively, neuron-specific post-translational steps in Env synthesis could be impaired, leading to aberrant Env synthesis in the CNS, resulting in accumulation of viral products detrimental to normal cell function or interfering with the processing of normal cellular glycoproteins, altering cell metabolism and/or viability.

Our results are intriguing in the light of human retroviral neurological diseases. Abortive replication of virus in neurons and/or glial cells could be involved in their pathogenesis. Similarities between human immunodeficiency virus (HIV) and human T-cell leukaemia virus (HTLV-1) neurological diseases and non-inflammatory neurodegenerative diseases of unknown aetiology (such as Alzheimer's disease and Creutzfeld-Jacob disease) have been pointed out and a retroviral aetiology suggested[15,16]. It may be that these diseases involve retroviruses, but because viral replication is abortive, viral infection of neurons and/or glial cells may be difficult to detect. Thus, our results give impetus to the investigation of abortive retroviral infection in the aetiology of these diseases. □

MULTIPLE sclerosis is thought to be an autoimmune disease of the central nervous system mediated by T cells specific for a myelin antigen[1,2]. Myelin basic protein has been studied as a potential autoantigen in the disease because of its role as an encephalitogen in experimental autoimmune encephalomyelitis and post-viral encephalomyelitis[3,4] and because of the presence in the blood of multiple sclerosis patients of *in vivo*-activated T cells reactive to myelin basic protein[5]. Immune involvement in multiple sclerosis has been further suggested by the association with the major histocompatibility complex class II phenotype DR2, DQw1 (refs 6–9). To define the T-cell specificity toward myelin basic protein, 15,824 short-term T-cell lines were established from multiple sclerosis subjects, subjects with other neurological diseases, and normal controls. Here we report a higher frequency of T-cell lines reactive with a DR2-associated region of myelin basic protein between residues 84–102 in patients with multiple sclerosis compared with controls. A second region, identified between residues 143–168, was recognized equally in multiple sclerosis patients and controls and was associated with the DRw11 phenotype. These DR2 and DRw11 associations were also observed among T-cell lines generated from family members of a multiple sclerosis patient. The immunodominant 84–102 peptide from myelin basic protein was both DR2- and DQwl-restricted among different T-cell lines. These results raise the possibility that this immunodominant region may be encephalitogenic in some DR2⁺ individuals.

A barrier to studying the fine specificity of reactivity to myelin basic protein (MBP) in multiple sclerosis (MS) has been the low level of reactivity in standard proliferation assays[10,11]. To obtain the necessary number of cells for analysis, short-term T-cell lines (15,824 in total) were generated from 51 subjects by culturing peripheral blood mononuclear cells with MBP and then adding interleukins-2 and -4 (IL-2 and IL-4). IL-4 increases the growth rate of T-cell clones[12] and 2.5×10^5–5.0×10^5 T-line cells were generated from every well plated to perform the required analysis. On day 13, each line was tested for reactivity to MBP; reactive lines were then tested for reactivity to overlapping 20-residue oligopeptides encompassing the human MBP sequence. For MHC restriction experiments, lines reactive to

an MBP peptide were restimulated for two more cycles, first with MBP and then with the specific MBP fragment recognized by that line. In a subgroup of patients, the frequency of T cells recognizing proteolipid apoprotein (PLP), another major encephalitogenic central nervous system antigen, was investigated[13,14].

Frequency analysis for MBP and PLP reactivity was performed on patients with definite, early relapsing-remitting MS, subjects with other neurological diseases with central nervous system tissue damage and normal subjects, age and sex matched to the MS patients (Table 1). Although the frequency of MBP-reactive lines was slightly higher in subjects with MS compared with the other subjects, this was not statistically different. There was more reactivity to PLP in patients with MS compared with those with other neurological diseases, but this did not reach statistical significance.

Of a total of 302 lines from patients with MS that could be expanded and confirmed to react with MBP on repeated analysis, 140 (46.4%) reacted with MBP residues 84-102. In the control groups, 11 of a total of 100 MBP-reactive T-cell lines (11.0%) recognized this MBP peptide. We calculated the actual frequency of T cells derived from the peripheral blood that reacted with each MBP peptide for each individual subject. The mean values of patients with MS and the control subjects are shown in Fig. 1*a*. The frequencies of peptide-specific lines from normal subjects and from other neurological disease controls were virtually identical and thus were combined for analysis. The mean frequency of T-cell lines selectively reactive to MBP residues 84-102 was higher in subjects with MS compared with controls, although there were no differences among groups in the relative stimulation indices of T-cell lines reacting to MBP peptides. Significant but less striking increases in the frequency of reactivity to MBP residues 61-82 and 124-142 were also observed in MS patients, whereas both MS and control subjects showed high frequencies of T-cell lines reactive with MBP residues 143-168.

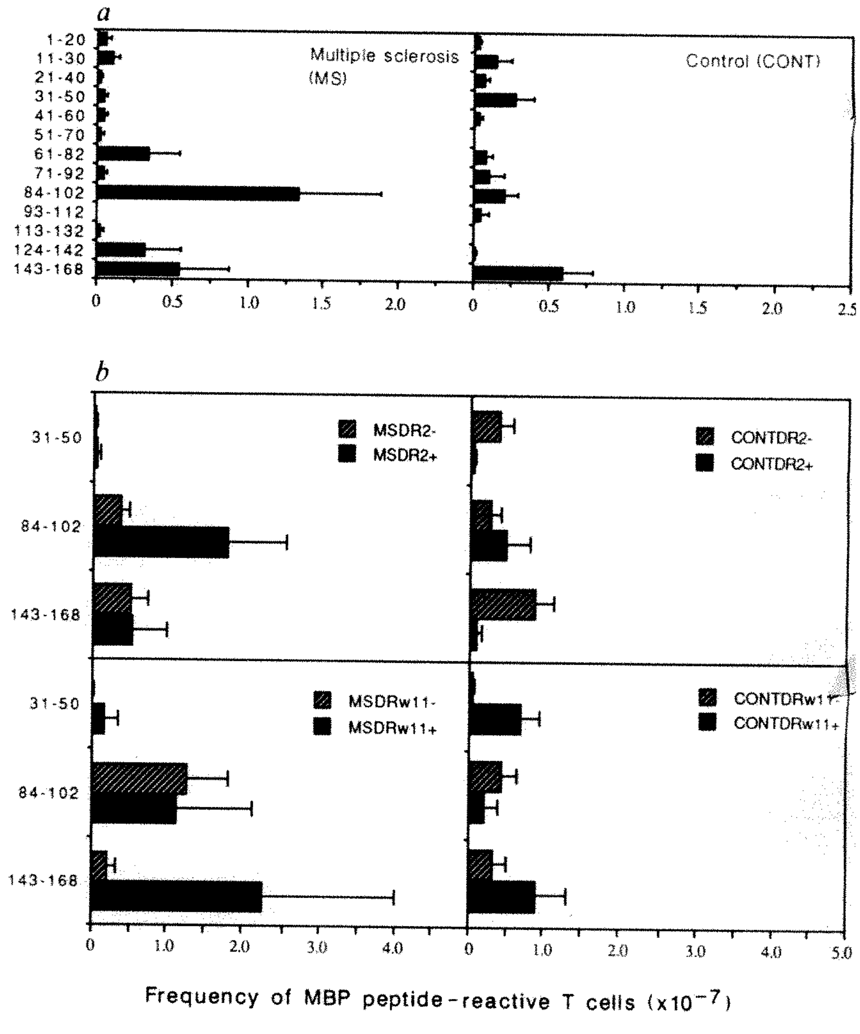

FIG. 1 *a*, Mean frequency of peripheral blood T cells recognizing overlapping synthetic peptides of human MBP in 23 MS patients and 16 randomly selected controls (10 subjects with other neurological diseases of the central nervous system and 6 normal controls). For each patient, 288 wells were plated with 2×10^5 blood mononuclear cells (MNC), separated by Ficoll density gradient sedimentation, in 96-well round-bottom plates. MNC were cultured with MBP (10 μg ml^{-1}) in media consisting of RPMI 1640, 10% pooled human serum, 1% HEPES buffer, 1% penicillin/streptomycin and 2% glutamine for 13 days. On day 3 and then every 3-4 days, 5% IL-2 (ABI, Columbia, MD) and 2 U ml^{-1} of rIL-4 (Genezyme, Boston) were added to the culture. On day 13, an aliquot of each T-cell line was analysed for reactivity to MBP by placing 10,000 cells from each T-cell line with 10,000 irradiated autologous MNC as antigen-presenting cells (APC) in duplicate for 72 h in a round-bottom 96-well microtitre plate and pulsing with [^{3}H]-thymidine during the last 18 h of culture. APC were prepared by pulsing 10^7 APC in 1.0 ml media with or without 100 μg MBP for 1 h at 37 °C. Lines positive for proliferation to MBP (defined as showing both a stimulation index of >3 and a Δc.p.m. of >500) were re-tested 72 h later for reactivity to 13 different peptides (concentration of antigen 100 μg peptide ml^{-1}) encompassing the human MBP sequence. MBP was extracted from human brain tissue, purified on a CM-52 column, and the highest relative molecular mass (M_r, 18,500) was used[24]. MBP peptides were synthesized by Biosearch Lab Inc., (San Rafael, California) using the solid phase method and were purified by HPLC. MBP peptide sequences are as follows (single-letter amino-acid code): 1-20, ASQKRPSQRHGSKYLATAST; 11-30, GSKYLATASTMDHARHGFLP; 21-40, MDHARHGFLPRHRDTGILDS; 31-50, RHRDTGILDSIGRFFGGDRG; 41-60, IGRFFGGDRGAPKRGSGKDS; 51-70, APKRGSGKDSHHPARTAHYG; 61-82, HHPARTAHYGSLPQKSHGRT; 71-92, SLPQKSHGRTQDENPVVHFF; 84-102 DENPVVHFFKNIVTPRTPP; 93-112, KNIVTPRTPPPSQGKGRGLS; 113-132, LSRFSWGAEGQRPGFGYGGR; 124-142, RPGFGYGGRASDYKSAHKG; 143-168, FKGVDAQGTLSKIFKLGGRD. In pilot experiments, plating 2×10^5 mononuclear cells per well gave frequencies of between 1 and 20% MBP-reactive lines. Thus according to the Poisson probability distribution, most MBP-reactive T-cell lines represent a single MBP-reactive T cell. As 2×10^5 MNC were plated for each of 288 wells per subject, the actual frequency of MBP-reactive T cells can be calculated by dividing the frequency of MBP reactive lines (Table 1) by 2×10^5. The frequency of T cells reactive with specific MBP synthetic peptides was calculated by multiplying the frequency of MBP-reactive T cells for each subject by the proportion of lines reactive with each peptide on the second analysis for that same subject. Specifically, the frequency of circulating T cells reactive with synthetic peptide is equal to the frequency of MBP-reactive T cells × (no. T-cell lines reactive with synthetic peptide)/(Total no. MBP reactive lines on 2nd analysis). The mean frequency ±s.e.m. for each peptide for patients with MS, normal controls and subjects with other neurological diseases were calculated. Values for both control groups were combined. *b*, Frequency of MBP peptide-reactive lines in relation to class II MHC expression in patients with MS and in controls. An additional 6 DR2$^+$ normal controls were studied in addition to the original 16 control subjects and 23 patients with MS. Subjects with the DR2 phenotype had a higher proportion ($P=0.003$) and frequency ($P=0.045$) of T cells recognizing MBP residues 84-102. Subjects with the DRw11 phenotype had a higher frequency ($P=0.006$) of T cells recognizing MBP residues 143-168 (unpaired *t*-test).

Patients with MS were Caucasian and had well-characterized early relapsing remitting disease with minimal disability with at least two exacerbations within the previous 24 months and positive lesions on MRI at the time of blood drawing. Subjects with other central nervous system diseases had the following diagnoses: 1-3 weeks after either cerebrovascular accident (4); brain trauma with central nervous system haemorrhage (4); metastatic brain tumour (2). The total number of lines reactive with either MBP or PLP and the total number of T-cell lines generated are shown. The frequencies of MBP- and PLP-reactive lines were calculated separately for each subject by dividing the number of MBP-reactive lines by the total number of lines generated and the mean value ±s.e.m. are given. See Fig. 1 legend for methods for T-cell cloning. ND, not determined.

(*a*) Proliferation of T-cell lines using a panel of different MNC as APC are shown. Five T-cell lines reactive to MBP residues 84–102 from subject Hy were expanded by repeated cycles of stimulation with autologous irradiated MNC pulsed with synthetic MBP peptide 84–102 and examined for recognition of this region of MBP and human MBP. Briefly, 50,000 T-line cells were plated in triplicate with 50,000 irradiated APC MNC for 72 h in round-bottom 96-well microtitre plates and wells were pulsed with [^{3}H]thymidine for the last 18 h culture. APC MNC were either cultured alone, pulsed with 100 μg ml^{-1} synthetic peptide 84–102 (the optimal concentration of peptide to induce proliferation), or pulsed with 100 μg ml^{-1} MBP. The average c.p.m. values for triplicate wells are shown. DR and DQw haplotypes are given and haplotypes common with the patient (top line), who was DR2, DR7, DQw1, DQw3, are in bold. (*b*) Inhibition of proliferation by class-specific anti-MHC monoclonal antibodies. The panel of five T-cell lines reactive with MBP residues 84–102 were plated with autologous APC MNC either alone or in the presence of APC pulsed with synthetic peptide 84–102, as above, in the presence of monoclonal antibodies (final concentration 1:100) recognizing different MHC class II gene products. Control was an irrelevant monoclonal antibody. Antibody nomenclature according to the 10th International Histocompatibility Workshop[25].

As previously reported[6-9], the DR2, DQw1 phenotype was infrequent in the controls and more common in MS patients (Table 1). An association was observed between the DR2 phenotype and both the proportion and the frequency of T-cell lines reactive to MBP residues 84–102 (Fig. 1*b*). To determine whether there was also this association in non-MS subjects, an additional six normal subjects with the DR2, DQw1 phenotype were investigated. An association with DR2 was also found among controls in terms of the proportion of T-cell lines reactive with MBP residues 84–102 (DR2$^+$ controls, 31.0±10.8%; DR2$^-$ controls, 10.1±0.4%). The total frequency of lines reactive with this region of MBP was, however, less than that in patients with MS (Fig. 1*b*). Although DQw1 is in linkage disequilibrium with DR2, independent analysis of peptide reactivity revealed no association with DQw1 phenotype. The lack of a DQw1 association in subjects with MBP peptide 84–102 reactivity may, however, also relate to differences in DQw1 polymorphisms that were not examined in the present study.

The DRw11 phenotype was more common in controls than in subjects with MS (Table 1). Its expression was associated with a higher frequency of lines reactive to MBP residues 143–168 in both MS patients and controls (Fig. 1*b*). Reactivity to MBP residues 31–50, which was predominantly observed in controls, was also associated with DRw11. Other MHC associations were not found.

It was important to determine the MHC restriction of the

The family members of an MS patient expressing the DR2, DQw1; DRw11, DRw52, DQw1 class II MHC haplotypes were examined for the frequency c T-cell lines reactive with MBP residues 84-102 and 143-168. MNC (2×10^5) in each of 288 wells (three 96-well round-bottom plates) were cultured wit MBP (10 μg ml^{-1}) as outlined above for each subject. On day 16, each T-cell line was analysed for reactivity to synthetic peptides corresponding to MB residues 84-102 and 143-168. The number of lines reactive with each peptide (SI > 3, Δc.p.m. > 500) generated per subject are shown. The actu stimulation indices were generally >20. P1 and P2, parents; S1-S3, siblings.

T-cell lines reactive with the immunodominant MBP epitope. Monoclonal antibody blocking studies of five T-cell lines reactive with MBP residues 84-102 suggested that both DR and DQ molecules could function as restricting elements. Among clones blocked by anti-DR monoclonal antibody, clone 2E11 proliferated in response to MBP residues 84-102 with the panel of DR2$^+$ antigen-presenting cells (APC) whereas 2C9 and 2H9 proliferated only with autologous APC (Table 2). The recognition of peptide by clones 1A8 and 3A10, which were partially blocked by anti-DQ monoclonal antibodies, was restricted to APC from the responder and one of two APC donor subjects expressing DQw1.

To investigate the relationship between MHC expression and frequency of T-cell reactivity to immunodominant MBP epitopes, a family with one afflicted sibling of both DR2 and DRw11 phenotypes was studied (Table 3). A total of 1,728 individual T-cell lines were generated from both parents and four siblings and the number of lines reactive with either MBP peptide 84-102 or 143-168 was determined. The DR2$^+$, DRw11$^+$ patient had a high frequency of T-cell lines reactive to both MBP residues 84-102 and 143-168. The DRw11$^+$ parent preferentially recognized MBP residues 143-168, whereas the DR2$^+$ parent preferentially recognized MBP residues 84-102. The frequency of MBP peptide reactive lines, however, was lower than that of the patient. One sibling was DR2$^+$ and preferentially recognized MBP residues 84-102. Of two HLA-identical siblings (DR4, DQw3/DRw6, DQw1), one preferentially recognized MBP peptide 84-102. Although DR4 or DQw1 may also restrict recognition of MBP residues 84-102, other factors such as inherited T-cell receptor polymorphisms may have influenced T-cell reactivity to the MBP autoantigen in one of the DR4, DQw3/DRw6, DQw1 siblings. In this regard, DR4 was also more frequent in our series of MS patients compared with control subjects. This family linkage analysis suggests that optimum recognition of immunodominant MBP eptitopes requires specific class II MHC alleles both in patients with MS and controls. In total, these studies indicate that although control subjects expressing DR2 seem preferentially to recognize the same MBP determinant as do DR2$^+$ MS patients, their clonal frequency in the blood is less than that of patients with MS.

Previous studies using peripheral blood have suggested there is a response to a number of MBP regions, in particular 83-96, which contains an epitope that overlaps with the immunodominant 84-102 MBP region identified here[15]. In those studies, however, the standard 7-day-proliferation assay did not detect peptide reactivity in controls. The presence of T cells reactive with MBP residues 84-102 in DR2$^+$ normal subjects suggests that other immune mechanisms exist to prevent the activation of circulating autoreactive T cells. Although in the present study MBP-reactive T cells could be generated by culture *in vitro* from controls to the same degree as patients with MS, recent work indicates that MBP-reactive T cells are activated only in patients with MS and not in controls[5]. Other factors involved in the development of autoimmune diseases may relat to the altered systemic immunoregulation seen in MS a evidenced by decreased levels of antigen-nonspecifi suppression[16,17].

In experimental autoimmune encephalomyelitis (EAE), a single immunodominant region of MBP influenced by class I MHC has been observed among different rat and mous strains[18-21] and these peptides are the major encephalitogen i the animal strain is susceptible to EAE[22]. In determing the relationship between MHC and encephalitogenic immunodominant regions of MBP, the animal need not have had EAE. Unprimed Lewis rat lymph-node cells selectively react with immunodominant MBP residues 48-88 and these T-cell clones are encephalitogenic[23]. The present experiments in humans define immunodominant regions of human MBP that are linked to a particular MHC. As the DR2, DQw1 phenotype is most common in patients with MS[6-9], the T-cell reactivity to MBP residues 82-102 in association with this phenotype may be analogous to the encephalitogenic T cells defined in EAE.

To show that MS is a cell-mediated autoimmune disease analogous to EAE, certain criteria can be proposed. First an association should exist between an immunodominant region of the presumed autoantigen and disease-associated class II MHC haplotypes. Second, there should be an increase in frequency of T cells that react with this immunodominant epitope. Finally, the course of the disease must be altered by elimination of autoreactive T cells or by inducing immune tolerance to the autoantigen identified in the first two criteria. This final condition implies that *in vitro* experiments on their own cannot prove the association of an autoantigen with a disease and instead clinical trials are necessary.

Our results have begun to address the first two criteria, showing an association between immunodominant regions of human MBP with the DR2 class II MHC phenotype and an increased frequency of T cells recognizing the MHC-linked immunodominant epitope of the MBP autoantigen in MS. In addition, PLP might also serve as an autoantigen. If MBP is a target autoantigen in MS, our results imply that an immunodominant region of MBP, between residues 84-102, is an encephalitogenic region in some DR2$^+$ individuals. In non-DR2 individuals other immunodominant MBP epitopes or other antigens may be associated with the disease.

Note added in proof: Since submitting our article, two works have come to our attention demonstrating similar immunodominant regions of human MBP: Martin, R. *et al.*, *J. Immunol* (in the press); Pette, M., *Proc. natn. Acad. Sci. U.S.A.* (in the press). □

Activated CD8 binding to class I protein mediated by the T-cell receptor results in signalling

Anne M. O'Rourke, Joy Rogers & Matthew F. Mescher*

Division of Membrane Biology, Medical Biology Institute, La Jolla, California 92037, USA

THE CD8 glycoprotein of T cells binds nonpolymorphic regions of class I major histocompatibility complex proteins on target cells[1,2] and these interactions promote antigen recognition and signalling by the T-cell receptor[3–11]. Studies using artificial membranes indicated that effective CD8/class I interaction is critical for response by alloantigen-specific cytotoxic T lymphocytes when class I protein is the only ligand on the antigen-bearing surface[10,11]. But significant CD8-mediated binding of cytotoxic T lymphocytes to non-antigenic class I protein could not be detected in the absence of the alloantigen[12]. These apparently contradictory findings indicate that CD8 binding to class I protein might be activated through the T-cell receptor and the results reported here demonstrate that this is the case. Treatment of cytotoxic T lymphocytes with soluble anti-T-cell receptor antibody activates adhesion of the cytotoxic T lymphocytes to class I, but not class II proteins. The specificity of this binding implies that it is mediated by CD8 and blocking by anti-CD8 antibodies confirmed this. Furthermore, binding of CD8 to class I protein resulted in generation of an additional signal(s) necessary to initiate response at low T-cell receptor occupancy levels.

Purified class I alloantigen can be immobilized on plastic and stimulates T-cell receptor (TCR) triggered degranulation by cloned cytotoxic T lymphocytes (CTL)[11]. Specific binding of ^{51}Cr-labelled CTL to the immobilized alloantigen can be measured (Fig. 1). Roughly 15–20% of C11 CTL, specific for H-2K^b, were bound following a 2-h incubation at 37 °C with immobilized K^b antigen. Nonspecific binding in wells blocked with fetal calf serum (FCS) or having immobilized class II (I-A^k) protein was only ~2%. No binding above this background level was found when non-antigenic class I proteins (H-2D^b or D^d) were immobilized. In numerous experiments, specific binding of 15–30% of the CTL to alloantigen has been observed, consistent with studies examining target-cell binding by cloned CTL (refs 13, 14).

To determine if CTL binding to irrelevant class I protein could be activated by the TCR, binding was measured after treating CTL with anti-TCR monoclonal antibody F23.1 in solution. Soluble F23.1 stimulated CTL binding to immobilized class I, but not to class II major histocompatibility complex (MHC) proteins (Fig. 1). Binding occurred equally well to the class I protein borne by the CTL (D^d) or to third-party class I protein (D^b) and was comparable to that obtained to alloantigen (K^b) in the absence of soluble anti-TCR monoclonal antibody. Stimulation of binding was specific for anti-TCR monoclonal antibody. Addition of irrelevant antibodies or antibodies specific for several other CTL surface proteins including H-2K^k, CD8 or Thy-1 did not trigger binding to class I proteins (data not shown). Binding to irrelevant class I proteins was detectable within minutes of adding anti-TCR antibody and centrifuging the cells into the wells, increased to 15–30% over the next hour, and then remained stable. Similar kinetics were observed for binding to alloantigen in the absence of soluble anti-TCR antibody (data not shown).

Neither soluble anti-TCR monoclonal antibody nor immobilized class I protein alone (other than the alloantigen) trigger CTL degranulation. Degranulation is triggered, however, by the combination of soluble anti-TCR antibody and immobilized class I proteins. As for binding, triggering of degranulation is

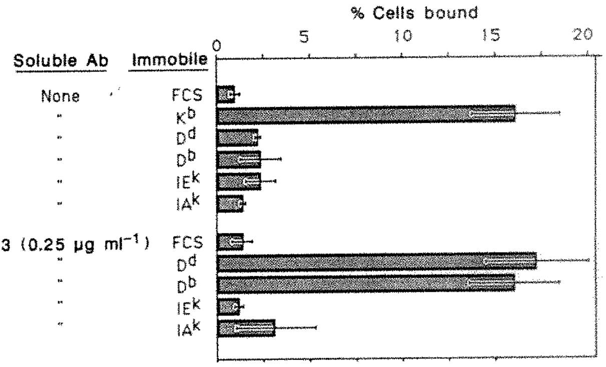

FIG. 1 Soluble anti-TCR monoclonal antibody triggers CTL binding to irrelevant class I protein. The indicated MHC proteins were immobilized (0.25 μg per well) and the wells blocked using 2% FCS. Binding by C11 was determined as described below using a 2.5-h incubation at 37 °C. Where used, soluble anti-TCR monoclonal antibody (F23.1) was added to the CTL suspension (final concentration 0.25 μg ml^{-1}) immediately before initiating the binding assay. For this experiment, total ^{51}Cr incorporation was 26,428 c.p.m. per 10^5 cells, and spontaneous release was 815 c.p.m. per 10^5 cells.

METHODS. Cloned CTL: The cloned CTL lines used included C6, C11 and C13. Characterization and maintenance of these have been described[11]. All were derived from B10.BR × B10.D2F1 (H-2^k × H-2^d) responder mice and were specific for the H-2K^b alloantigen. MHC protein purification and immobilization: MHC class I and II proteins were purified by monoclonal antibody affinity chromatography and immobilized on plastic as previously described[11,31]. In brief, purified antigen in 0.5% deoxycholate was diluted in PBS, pH 7.2, to a final concentration of 1 or 2 μg ml^{-1}, added to wells of a plastic microtitre plate (Falcon 3912 Flexible Assay Plate), allowed to bind 1.5 h at 25 °C and unbound protein then removed. Then 2% FCS was added to the wells for 0.5 h to block unoccupied sites. Assay of CTL binding: CTL were labelled by incubating for 1 h at 37 °C using 100 μCi Na^{51}Cr per 10^7 cells. Cells were then washed and resuspended in RPMI medium containing 2.5% newborn calf serum (10^6 per ml). Binding was initiated by adding 10^5 cells per well in 0.1 ml and centrifuging at 1,200 r.p.m. for 1 min. Plates were then incubated for 1–2.5 h at 37 °C in 5% CO$_2$. After this, 0.1 ml PBS per well was added, plates placed on an ice water bath for 10 min and unbound cells removed by pipetting 10 times with a Pipetman (Gilson, Inc.). Well bottoms were then cut off and radioactivity levels determined. Spontaneous release of ^{51}Cr was determined for cells incubated under identical conditions. Binding was calculated as percentage cells bound = 100 × (c.p.m. bound)/(total c.p.m. − spontaneous c.p.m.). Visual counting confirmed that this procedure provided an accurate measurement of bound cells. Antibodies used: the monoclonal antibodies used in this study were F23.1 anti-TCR, 145-2C11 anti-T3, 53-6.7 anti-Lyt-2 (CD8), YTS 169.4 anti-Lyt2, 31-68.8 anti-Lyt-2, HO-13-4 anti-Thy-1.2, 11-4.1 anti-H-2K^k and anti-SASD, a murine IgG specific for a chemical hapten. The sources and purification of these antibodies have been described previously[11].

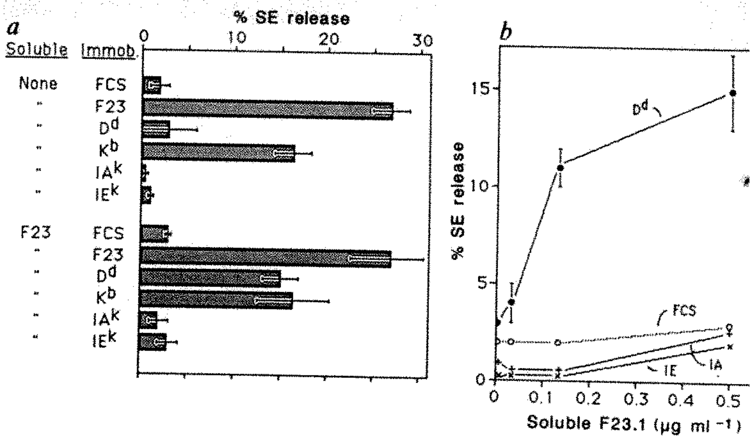
FIG. 2 CD8 binding to class I protein provides signalling necessary for the degranulation response. *a*, C11 CTL (10^5 per well) were added to wells containing the indicated immobilized protein (Immob.). When used, F23.1 anti-TCR monoclonal antibody was added to the CTL suspension at a final concentration of 0.5 μg ml^{-1} immediately before CTL were added to the wells. Cells were centrifuged and plates incubated for 2.5 h at 37 °C. After this, aliquots of supernatant were removed and assayed for serine esterase (SE) activity as previously described[11]. *b*, Triggering of serine esterase release was determined as described above, except the concentration of soluble F23.1 monoclonal antibody was varied as indicated. Wells contained immobilized H-2D^d (●), I-A^k (+), I-E^k (×), or FCS (○).



specific for class I (H-2D^d) and not class II (I-A^k) proteins (Fig. 2) and is dependent on the level of anti-TCR monoclonal antibody present (Fig. 2*b*). Additional experiments have shown that D^d, D^b and K^k class I proteins are all effective and that response occurs only when the soluble antibody is directed against the TCR. Thus, binding of CTL to class I protein, triggered by the TCR, results in generation of an additional signal(s) for the response.

The binding and class I-dependent response detected in these experiments is probably mediated by CD8; the alternative is that CTL have an additional, unidentified receptor that specifically binds class I conserved determinants. Although TCR may have a low affinity for self-MHC, there is no apparent contribution from this, as class I proteins are bound and stimulate equally well whether or not they are the same as those present on the responder cells. Further evidence that CD8 mediated the binding was that soluble anti-CD8 antibody blocked binding to class I protein triggered by soluble anti-TCR antibody (Fig. 3), although control antibodies including anti-Thy-1 did not (data not shown). Anti-CD8 antibody also effectively blocked degranulation in response to the combination of soluble anti-TCR antibody and class I protein. By contrast, immobilized anti-TCR antibody stimulated a comparable level of degranulation but the response was only marginally affected by anti-CD8 antibody (Fig. 3), indicating that little or no anti-CD8-induced negative signalling was occurring under the conditions used.

These results indicate that perturbation of the TCR generates a signal to activate CD8 binding to class I protein. Several phosphorylation events occur on T-cell triggering, including phosphorylation of the CD8 protein[15]. Protein kinase inhibitors K252a and staurosporine inhibited anti-TCR-triggered binding to class I protein (Fig. 4) with 50% inhibitory concentrations (IC$_{50}$s) similar to those found in studies directly examining inhibition of kinase activities. In addition to inhibition of binding, degranulation was inhibited (data not shown). Thus a kinase, possibly protein kinase C, is likely to be involved in TCR-dependent activation of CD8 binding. A kinase may also be involved in the signalling resulting from CD8/class I binding. CD8 is associated with p56^{lck} protein-tyrosine kinase[16], which can phosphorylate the ζ-subunit of the TCR complex. If CD8 binding to class I protein activates p56^{lck} to phosphorylate ζ-chain, as seems to occur on CD4 cross linking[17], this might modify signalling occurring through the occupied TCRs and result in the initiation of response. A mechanism involving CD8 feedback to the TCR complex is compatible with the fact that a response can be triggered through the TCR without a CD8 ligand, as occurs with immobilized anti-TCR monoclonal antibody (Figs 2 and 3; refs 11, 18) or in CTL lacking CD8 (ref. 19).

Synergistic signalling through anti-TCR and anti-CD8 or anti-CD4 antibodies has been used to suggest that the most effective signalling involves a trimolecular complex, with TCR and CD8 (or CD4) interacting with the same MHC protein[20-24]. This mechanism could account for the fact that, in general, class I-restricted cells carry the CD8 antigen and class II-restricted cells carry the CD4 antigen. Formation of trimolecular complexes is unlikely in the experiments described here, as the TCR and CD8 do not use the same ligand. However, this does not eliminate the possibility that a physical association between TCR and CD8 is critical, and that this occurs even when the two receptors interact with different ligands.

Although CD8/class I binding by CTL was not observed in the absence of a TCR stimulus (Fig. 1), chinese hamster ovary (CHO) cells transfected with the CD8 α-chain gene bind to class I-bearing cells[1]. Binding by these TCR-negative cells was observed in the absence of any stimulus. But binding was observed only when very high surface levels of CD8 were expressed in these transfectants. Thus, it seems likely that CD8 has some affinity for class I protein in the unactivated state, but that this is detectable only at high surface densities of CD8. By contrast, with the CD8 surface density normally present on T

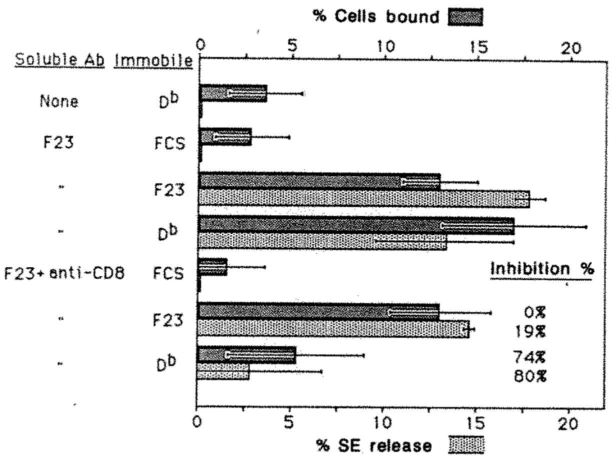


FIG. 3 Anti-CD8 antibody blocks TCR-activated binding and response to non-antigenic class I protein. The ^{51}Cr-labelled clone 11 CTL (10^5 per well) were incubated for 20 min at room temperature alone or with soluble F23.1 anti-TCR monoclonal antibody (.25 μg ml^{-1}). Where used, YTS 169.4 monoclonal antibody (as ascites) was then added at a 1:900 dilution. YTS 169.4 is a rat monoclonal antibody that recognizes a monomorphic murine Lyt-2 determinant[32]. Cells were then added to wells bearing the indicated immobilized protein, centrifuged and the plates incubated for 3 h at 37 °C. After this, aliquots of supernatant were removed and assayed for serine esterase (SE) activity[11]. Binding was then determined in the same wells as described (Fig. 1). Parallel comparisons of unlabelled and ^{51}Cr-labelled CTL have shown that ^{51}Cr-labelling has no effect on the degranulation response (data not shown). H-2D^b antigen used at 0.2 μg per well.

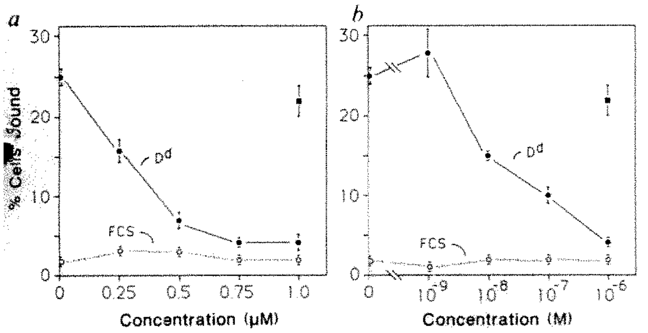

FIG. 4 Inhibition of TCR-activated CD8/class I binding by kinase inhibitors. Soluble F23.1 anti-TCR monoclonal antibody (0.25 μg ml^{-1}) was added to ^{51}Cr-labelled C11 CTL immediately before initiating binding to wells containing H-2D^d (0.1 μg per well; ●) or FCS (○). K252a (*a*) or staurosporine, (*b*) (Calbiochem) were added in dimethylsulphoxide (DMSO) (≤1% final concentration) to CTL 15 min before initiating binding. DMSO was added to solvent controls (■; 1% final concentration). Binding was for 2.5 h at 37 °C. Total ^{51}Cr incorporation was 40,298 c.p.m. Spontaneous release was determined at all drug concentrations and did not vary significantly. The average spontaneous release for all samples was 1,308 c.p.m.

cells, binding is only detected on activation through the TCR (Fig. 1).

Possible mechanisms by which TCR signalling might activate CTL binding mediated by CD8 include: rapid translocation of an internal pool of CD8 to the cell surface (preliminary results indicate that this does not occur on addition to CTL of soluble anti-TCR monoclonal antibody); induced microclustering of CD8, a mechanism implicated for PMA-activation of binding by C3bi receptors[25]; or conversion of CD8 from a low-affinity to a high-affinity state on TCR signalling. An example of the latter is provided by several hormone and growth-factor receptors whose affinity for ligand is modulated by phosphorylation[26]. These mechanisms are not mutually exclusive and more than one could contribute to activation of CD8 binding.

Results reported here demonstrate that CD8/class I interactions represent a TCR-activated adhesion-signalling system. Another adhesion system important in T-cell responses, that of LFA-1 and its I-CAM 1 and 2 ligands[27,28], is activated by crosslinking the TCR[29,30]. Whether the binding of LFA-1 to I-CAM mediates signalling events that contribute to TCR-dependent responses is not known. Adhesion-strengthening mechanisms triggered by TCR recognition of antigen, but distinct from TCR-antigen bonds, have been proposed, and Martz[28] has discussed in detail how such mechanisms can account for the properties of CTL/target cell interactions. It now seems that both LFA-1/I-CAM and CD8/class I represent such mechanisms, with at least the CD8/class I interaction also resulting in generation of a signal(s) for response. □

Small G proteins are expressed ubiquitously in lymphoid cells and do not correspond to Bcl-2

Katherine Monica, Zehava Chen-Levy & Michael L. Cleary

Laboratory of Experimental Oncology, Department of Pathology,
Stanford University Medical Center, Stanford, California 94305, USA

THE *bcl*-2 gene is consistently associated with t(14; 18) chromosomal translocations[1–6] observed in a large fraction of human B-cell lymphomas[7–8]. The t(14; 18) translocation results in deregulated expression of the *bcl*-2 gene[5] and synthesis of inappropriately high levels of the Bcl-2 protein[9,10]. Gene transfer studies suggest a role for Bcl-2 in cell survival[11,12], growth enhancement[13,14] and oncogenic transformation[11,15]. To test the suggestion that GTP-binding by Bcl-2 may mediate its biological effects[16] we characterized the GTP-binding proteins in lymphoid cells expressing Bcl-2. Expression of several small GTP-binding proteins was found to be ubiquitous and did not vary with levels of Bcl-2. By using immunological, electrophoretic and cell-fractionation techniques, we separated Bcl-2 from G proteins of small relative molecular mass (M_r) and showed that it is incapable of binding GTP. Our results show that small M_r G proteins are widely expressed in lymphoid cells and that Bcl-2 is not a novel member of this GTP-binding protein family.

The prevalence of small M_r G proteins in cells of the B-cell lymphoid lineage was investigated using a GTP-binding assay[17,18] that identifies the small M_r GTP-binding proteins but not the large G proteins with an $\alpha\beta\gamma$ subunit structure[19]. The cell lines examined corresponded to different stages of B-cell maturation and included pre-B cells (leukaemia line 697), mature B cells (lymphoma lines SU-DHL-4, DUL-5 and FL18) and plasma cells (murine plasmacytoma line J558L). In all lines, four small M_r GTP-binding proteins similar to those observed in NIH 3T3 cells were detected (Fig. 1). A fifth GTP-binding protein of M_r 21,000 (21K), recognized by the Ras11 monoclonal antibody[20], was also found in some lines.

In spite of the uniform expression of small M_r G proteins in these B-cell lymphoma cell lines, there were marked differences in Bcl-2 expression (Fig. 1), which ranged from very high levels in FL18 to undetectable levels in SU-DUL-5. There was also no obvious increase in GTP-binding activity or additional GTP-binding proteins in cell lines that overexpressed Bcl-2, or in the *bcl*-2-transfected EP5 cells compared with their non-transfected counterpart J558L (Fig. 1). These observations suggested no correlation between levels of GTP-binding and Bcl-2 expression.

The GTP-binding potential of Bcl-2 was more directly assessed after immunoprecipitation from total cellular extracts. Bcl-2 was the only protein specifically precipitated with anti-Bcl-2 antibodies as compared with pre-immune serum (Fig. 2*a*). The immune pellets and supernatant fractions were analysed for the presence of Bcl-2 (by anti-Bcl-2 western blot analysis) and for GTP-binding activity (by exposing the nitrocellulose-immobilized proteins to [α-^{32}P]GTP). Bcl-2 was found exclusively in the immune pellets, and had been efficiently cleared from the supernatant fractions under these conditions (Fig. 2*b*, lower panel). By contrast, no GTP-binding proteins were detected in the immune pellets (Fig. 2*b*, upper panel) as they remained completely in the supernatant fractions. These results showed that, using highly specific anti-Bcl-2 antibodies, Bcl-2 can be completely dissociated from the small M_r G proteins present in B lymphocytes, further suggesting that Bcl-2 does not bind GTP under the conditions used.

It is unlikely that the lack of observed GTP-binding by Bcl-2 immunoprecipitates (which contrasts with results reported earlier[16]) resulted from inactivation of the protein, as the GTP-binding activity of the small M_r G proteins remained intact following incubation with our antiserum. Furthermore, Ras immunoprecipitated from FL18 cells with the Ras11 antibody could renature to bind GTP under our experimental conditions (unpublished observations). Low levels of GTP-binding by Bcl-2 in our immunoprecipitates were ruled out by prolonged overexposure of the autoradiographs (data not shown). Finally, a recombinant Bcl-2 protein overexpressed at high levels in *Escherichia coli*[10] failed to bind GTP in conditions in which the recombinant Ras protein binds[21].

Bcl-2 has a predicted M_r of 26K but migrates in SDS-PAGE with a lower apparent M_r of ~24K (ref. 10). So it seems to co-migrate in SDS-PAGE with an ubiquitous small M_r G protein of B cells. We found electrophoretic conditions (Fig. 3*a*), however, in which the Bcl-2-reactive band on western blot analysis migrated in a slightly different position from this non-Bcl-2 small M_r G protein. Whereas the apparent M_r of Bcl-2 is 24K, the apparent M_r of the co-migrating GTP-binding protein was estimated to be 23.5K.

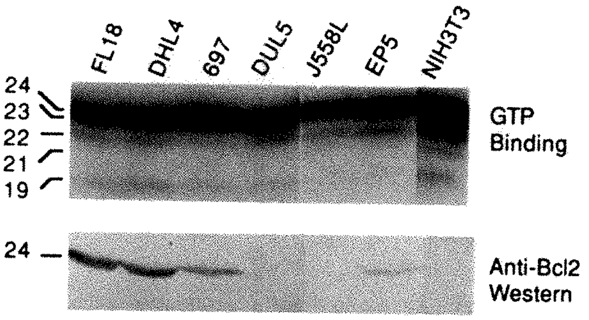

FIG. 1 Expression of Bcl-2 and low M_r GTP-binding proteins in various lymphoid and nonlymphoid cell lines. Upper panel, binding of [α-^{32}P]GTP to proteins from total cellular extracts. Lower panel, western blot of total cellular proteins using anti-Bcl-2 antibodies. Cell extracts were prepared from human B-cell lymphoma cell lines FL18, DHL4 and DUL5; human pre-B leukaemia cell line 697; mouse lymphoid cell line J558L and its Bcl-2-transfected counterpart EP5; and nontransfected NIH 3T3 cells. M_r values were determined by comparison with prestained protein standards electrophoresed in the gels.

METHODS. Cells were lysed over 30 min in buffer containing 50 mM HEPES, 150 mM NaCl, 0.5% Triton X-100, and 1 mM PMSF. Cell lysates were centrifuged at 1,000 r.p.m. for 6 min at 4 °C and extracts (5×10^6 cell equivalents per lane) prepared for 11.5% SDS-PAGE by boiling 5 min in sample buffer (0.1 M Tris-HCl, pH 6.8, 1% SDS, 0.1 M DTT). Proteins were electro-transfered to nitrocellulose using transfer buffer (50 mM Tris-HCl pH 7.4, 40 mM glycine, 1 mM SDS, 20% methanol). For GTP binding the membrane was incubated overnight at 4 °C (or 30 min at 25 °C) in binding buffer (50 mM Tris-HCl, pH 7.4, 5 mM $MgCl_2$, 0.3% Tween-20, 0.5 mM EDTA) followed by 1-h incubation at 37 °C (or 25 °C) in binding buffer plus 0.05 mCi [α-^{32}P]GTP (10 mCi ml^{-1}, Amersham 3,000 Ci mmol^{-1}). The blot was washed three times (5 min each) in binding buffer at 4 °C (or 25 °C), dryed, and autoradiographed. The membrane was then subjected to western blot analysis as previously described using anti-Bcl-2 antibodies[10].

In addition, cellular fractionation studies showed that the small GTP-binding proteins are distributed differently among various subcellular fractions compared with Bcl-2. The 23.5K and 23K small M_r G proteins were partly soluble and equally distributed between the cytosol and membrane fractions (Fig 3*b*, upper). Bcl-2, on the other hand, was not present in the cytosol and was distributed between the nuclear and membrane fractions (Fig. 3*b*, lower), consistent with its properties as an insoluble membrane-bound protein predominantly localized to the rough endoplasmic reticulum and the nuclear envelope[10].

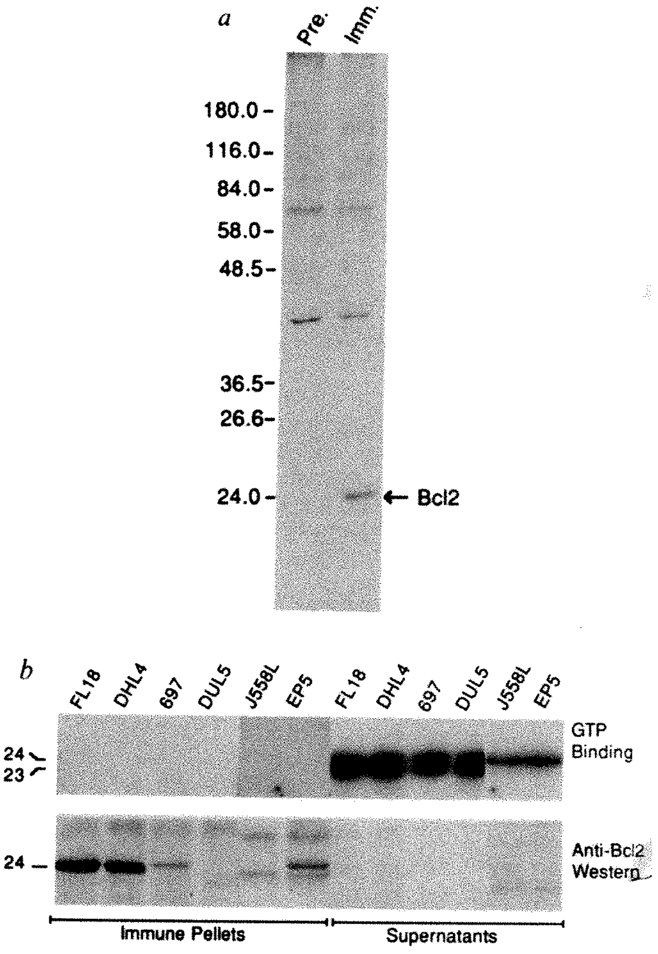

FIG. 2 Bcl-2 immunoprecipitation and GTP-binding. *a*, Immunoprecipitation of Bcl-2 from metabolically labelled FL18 cells. Pre., immunoprecipitation performed using pre-immune rabbit serum; Imm., immunoprecipitation with anti-Bcl-2 immune serum. *b*, GTP-binding (upper panel) and anti-Bcl-2 western blot analysis (lower panel) of proteins precipitated (Immune pellets) or remaining in the supernatant fraction (Supernatants). M_r standards were those described in Fig. 1.

METHODS. *a*, FL18 cells were metabolically labelled with [^{35}S]methionine for 6 h in methionine-free DME medium (15 mCi ml^{-1}, Amersham >1,000 Ci mmol^{-1}) and washed twice in cold PBS. Cell extracts were prepared as in Fig. 1 and immune complexes were formed overnight at 4 °C by incubating cell lysates with rabbit polyclonal serum highly specific for Bcl-2 as described elsewhere[10,30]. Immune complexes were collected on Sepharose protein-A beads (Pharmacia) at 4 °C for 2 h. Immune pellets were washed sequentially with two SDS washes (Fig. 1 lysis buffer with 0.1% SDS and 0.1% Triton X-100), one NaCl wash (lysis buffer with 1 M NaCl and 0.1% Triton X-100), and one SDS wash, and prepared as in Fig. 1 for 10% SDS-PAGE. *b*, Immunoprecipitation and sample preparation of unlabelled cellular proteins was carried out as described above; immune pellets and corresponding supernatant fractions were electrophoresed on 11.5% SDS-PAGE gels except for J558L and EP5 which were electrophoresed on 7.5–11.5% gradient SDS-PAGE gels. Proteins were transferred to nitrocellulose filters and subjected to GTP-binding analysis and anti-Bcl-2 immunoblotting as described in Fig. 1.

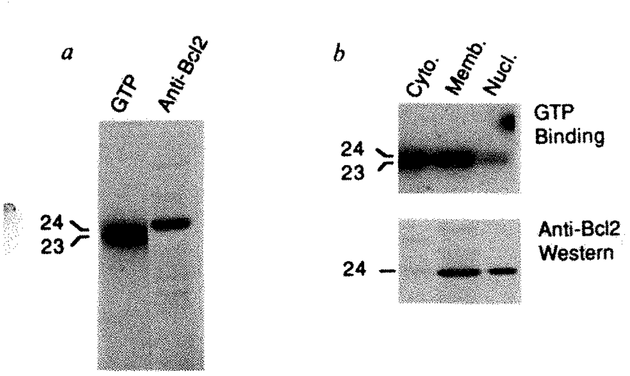

FIG. 3 Physical and biochemical fractionation of Bcl-2 and small M_r G proteins in lymphoid cells. *a*, Migration differences of Bcl-2 and small M_r GTP-binding proteins on SDS-PAGE gels. Total cellular proteins were fractionated by 11.5% SDS-PAGE and a single gel lane was subjected sequentially to GTP-binding (lane GTP) and anti-Bcl-2 western blot (anti-Bcl-2) analyses. Western filter and corresponding autoradiograph were aligned to show small but reproducible differences in migration for Bcl-2 and small M_r G proteins of 24K. *b*, Cellular fractionation demonstrating subcellular distributions of Bcl-2 and small M_r G proteins. Upper panel, GTP-binding analysis; lower panel, subsequent western blot analysis of the same filter. Cyto., soluble cytoplasmic fraction; Memb., cytoplasmic membrane fraction; Nucl., nuclear fraction. METHODS. *a*, FL18 cell extract was prepared as described (Fig. 1). *b*, Cell fractionation was performed as previously described[10]. Samples were run on 11.5% SDS-PAGE and subjected to GTP-binding and anti-Bcl-2 western blot analyses (Fig. 1, methods).

The above observations indicate that Bcl-2 is not one of the small M_r G proteins expressed ubiquitously in the lymphoid cell lines investigated here. The possibility that Bcl-2 binds GTP under other conditions seems unlikely as we have been unable to detect significant binding of GTP in Bcl-2 immune pellets that have not been subjected to denaturing conditions (unpublished observations). These results are consistent with the absence of significant sequence similarity of Bcl-2 with GTP-binding proteins, particularly in the highly conserved region of the 'phosphate-binding' consensus sequence (Gly-X-X-X-X-Gly-Lys) (ref. 22). Previous study of potential GTP binding by Bcl-2 (ref. 16) did not account for the ubiquitous small-M_r G proteins and may have been hampered by the reduced specificity of anti-peptide antibodies as reported by others[23]. The small M_r G proteins that we have observed in B lymphocytes may correspond to those described previously in other haematolymphoid cells. The 23.5K and 23K proteins seem similar to those in platelets and neutrophils[17-18], and one may correspond to the *ral* gene product[24]. The 19K GTP-binding protein most probably is Rho (ref. 25). A 22K GTP-binding protein has also been found in platelets and probably represents the protein variously called Smg21, Krev or Rap1[26-29]. As none of the small M_r GTP-binding proteins in B lymphocytes corresponds to Bcl-2, the biochemical role of this proto-oncogenic protein remains to be determined. ☐

The c-*ets* proto-oncogenes encode transcription factors that cooperate with c-Fos and c-Jun for transcriptional activation

CELL transformation by oncogenes leads to changes in gene expression. A key event in this process seems to be activation of the transcription factors AP-1 and PEA 3 (refs 1–5). Their synergistic activities are required for efficient activation of transcription from different promoters by many different oncogenes, serum growth factors and the tumour promoter TPA[4,5]. We show here that the products of the *ets*-1 and -2 proto-oncogenes, whose biological function was previously unknown[6–11], are transcription factors that activate transcription through the PEA 3 motif. The p68$^{c\text{-}ets\text{-}1}$ protein specifically binds to DNA and contains a transcriptional activation domain. The *ets*-like gene family therefore seems to encode a new family of transcription factors, apparently unrelated to other transcription factors. The p68$^{c\text{-}ets\text{-}1}$ protein cooperates with c-Fos and c-Jun (components of AP-1) for activation of transcription from the oncogene-responsive domain of the polyoma enhancer, indicating that combined activity of all three oncoproteins could be involved in the response of cells to growth stimuli.

A 14-base pair (bp) sequence from the polyoma (Py) enhancer (Fig. 1, oncogene-responsive domain) mediates transcriptional activation by serum growth factors, the tumour promoter TPA (12-*O*-tetradecanoylphorbol-13-acetate) and several oncogenes[4]. We found that expression of p68$^{c\text{-}ets\text{-}1}$ protein in LMTK$^-$ fibroblasts efficiently activated transcription through this 14-bp sequence (~20-fold; Fig. 1*b*, lanes 2, 3, 5, 6, 10, 12). Mutations in the PEA 3 motif of this element abolished p68$^{c\text{-}ets\text{-}1}$ activation (four tandem copies of sequences with mutations M1, M3 or M6; Fig. 1*c*, lanes 2–4, 9–11). Mutations in the AP-1 motif did not hamper efficient activation (four tandem copies of sequences with mutations M7, M4 or M5; Fig. 1*c*, lanes 5–7, 12–14). Expression of p68$^{c\text{-}ets\text{-}1}$ activated transcription through a PEA 3 motif multimer (~10-fold; Fig. 1*b*, lanes 7, 10, 9, 12), demonstrating that the PEA 3 motif is sufficient for transactivation by p68$^{c\text{-}ets\text{-}1}$.

To investigate whether p68$^{c\text{-}ets\text{-}1}$ binds to the PEA 3 motif, p68$^{c\text{-}ets\text{-}1}$ was synthesized in rabbit reticulocyte lysates and used for gel-retardation experiments with a PEA 3 oligonucleotide probe. A retarded complex that was absent from control extracts was observed (Fig. 2, lanes 1, 3, 4). No such complex was observed when an M1-mutated PEA 3 probe was used (lanes 5, 7). This mutation prevents transactivation by p68$^{c\text{-}ets\text{-}1}$ (Fig. 1*c*). Competition experiments showed that the wild-type sequence was the better competitor (Fig. 2, compare lanes 12-15 with 8-11). These results show that p68$^{c\text{-}ets\text{-}1}$ specifically binds to the PEA 3 motif.

Transcription factors contain activation domains that can stimulate transcription when fused to a heterologous DNA-binding domain. The p68$^{c\text{-}ets\text{-}1}$ protein fused to the DNA-binding domain of the bacterial repressor LexA (LexA-ets68) activated transcription through the *lexA* operator (Fig. 3, lanes 3, 7). Expression of either LexA alone, or unfused LexA with p68$^{c\text{-}ets\text{-}1}$, had no effect on transcription (Fig. 3, lanes 1, 2, 5, 6). Coexpression of inactive LexA inhibited LexA-ets68 (Fig. 3, lanes 3, 4, 7, 8), indicating that LexA competes with LexA-ets68 for binding to the operator and thereby inhibits its activity. These results are consistent with the presence of one or more transcriptional activation domains in p68$^{c\text{-}ets\text{-}1}$.

We previously suggested that there are cooperative interactions between PEA 3 and AP-1 (ref. 4). We tested whether p68$^{c\text{-}ets\text{-}1}$ could complement AP-1 (c-Fos and c-Jun) to activate transcription from the Py oncogene-responsive domain. Expression in LMTK$^-$ cells of limiting amounts of p68$^{c\text{-}ets\text{-}1}$ or c-Fos and c-Jun proteins led to low levels of activation of the reporter recombinant containing four copies of the B sequence (4- and 20-fold respectively, compared with the effects on the pG1 control reporter; Fig. 4, lanes 5-7 and 1-3). By contrast, coexpression of p68$^{c\text{-}ets\text{-}1}$ with AP-1 led to a much greater activation (250-fold; Fig. 4, lanes 4 and 8). It is of interest that a monomer B sequence is not detectably activated by either p68$^{c\text{-}ets\text{-}1}$ or AP-1 expression, and their combined effect is required for efficient activation (results not shown). Both the c-Ets-1 and AP-1 binding sites are required for cooperativity, as p68$^{c\text{-}ets\text{-}1}$ and AP-1 activate only through their corresponding motifs (ref. 4 and Fig. 1*c*). There was no complementation when only one of the motifs (PEA 3 or AP-1) was present in the reporter (results not shown). Mutations in part of either motif in the oncogene-responsive domain diminished activation by combined expression of p68$^{c\text{-}ets\text{-}1}$ and AP-1, but to a lesser extent than would be expected from the effect of the mutation on activation by one of the factors alone (results not shown). These data show that p68$^{c\text{-}ets\text{-}1}$ can cooperate with AP-1 in transcriptional activation. Expression of p68$^{c\text{-}ets\text{-}1}$ inhibits basal-level transcription from the oncogene-responsive domain when its own binding site is mutated (0.1-, 0.2- and 0.2-fold for M1, M3 and M6 respectively), but only when the AP-1 site is present

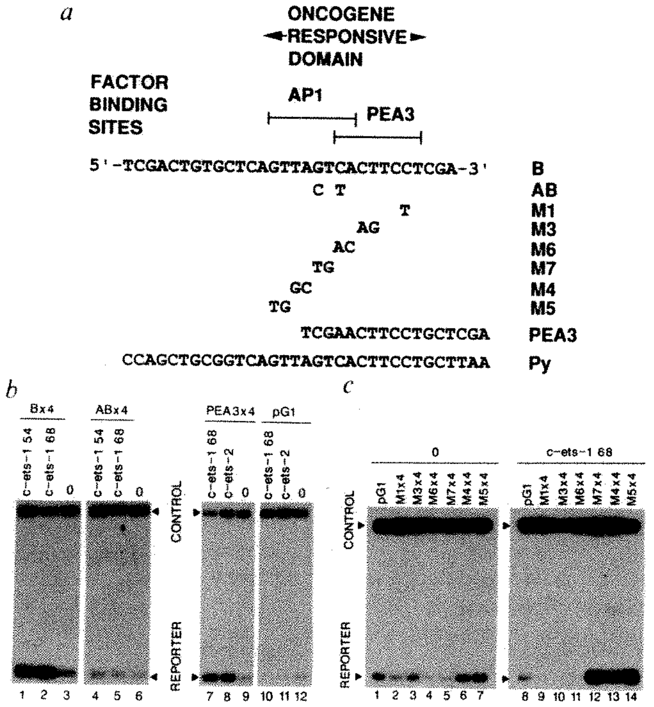

FIG. 1 *a*, Sequence of transcription elements. Transcriptional activation by the oncogene-responsive domain is measured by the ability of the transcription elements to stimulate transcription from the β-globin gene promoter in the reporter recombinant gene pG1 (ref. 4). The inserts are either four tandem copies of mutants B, AB or M1-M7 (B×4, AB×4, M1-M7×4) or one copy of the sequences shown. The oncogene-responsive domain of the Py enhancer contains specific binding sites for the transcription factors AP-1 and PEA 3. The extent of the PEA 3 site in the B sequence is deduced from the ability of the wild-type and mutated sequences to specifically mediate PEA 3 binding. The PEA 3 oligonucleotide contains the PEA 3 motif as defined by Martin *et al.*[23]. This sequence contains several additional nucleotides from the Py enhancer which compensate functionally for the loss of the C nucleotide that is mutated in the AB oligonucleotide (data not shown, see text). *b*, Activation of transcription by members of the *ets* gene family. LMTK$^-$ mouse fibroblasts were transfected with 1 μg reporter recombinants (inserts B×4, AB×4, PEA 3×4 or none (pG1)), 0.5 μg internal control plasmid (pβCB×2, ref. 4), and 0.5 μg expression vectors for p68$^{c\text{-}ets\text{-}1}$, p54$^{c\text{-}ets\text{-}1}$ or p58-64$^{c\text{-}ets\text{-}2}$. *c*, p68$^{c\text{-}ets\text{-}1}$ activates transcription through the PEA 3 motif. LMTK$^-$ fibroblasts were transfected with 1 μg reporter recombinants (inserts 4×M1, M3, M6, M7, M4 or M5, or none (pG1)), 0.5 μg internal control (pβCB×2) and 0.5 μg c-Ets-1 68 expression vector (lanes 8-14) or the expression vector pSG5 without an insert (lanes 1-7). Reporter and control indicate the corresponding specific S1 nuclease-resistant products.

METHODS. LMTK$^-$ cells were transfected with the indicated recombinants by the DEAE dextran and chloroquine technique. The cells were incubated in low-concentration serum for 48 h, then total RNA extracted and analysed by quantitative S1 nuclease mapping for RNAs specifically initiated from the β-globin gene promoter of the reporter recombinant and the conalbumin gene promoter of the internal co-transfected control recombinant[4]. The expression vectors contain the corresponding *c-ets* complementary DNA sequences in the multiple cloning site of the pSG5 expression vector[24].

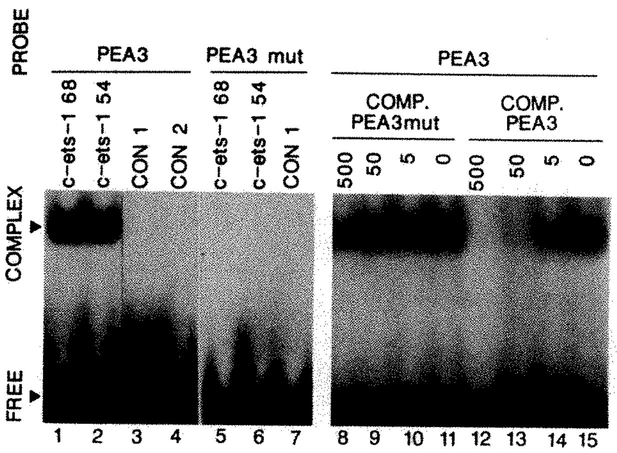

FIG. 2 *In vitro*-synthesized c-Ets-1 specifically binds to the PEA 3 motif. The p68$^{c\text{-}ets\text{-}1}$ and p54$^{c\text{-}ets\text{-}1}$ proteins were translated in rabbit reticulocyte lysates (Amersham; as described in the manufacturer's instructions) from RNA transcribed by T7 polymerase from linearized pSG5 expression vectors[24] containing cDNAs for c-Ets-1 68 (lanes 1, 5, 8-15), c-Ets-1 54 (lanes 2, 6), or no insert (CON1, lanes 3, 7). Control experiments showed that full-length c-Ets-1 proteins were efficiently synthesized in these lysates. Aliquots (2 μl) were used for gel-retardation assays with either wild-type (lanes 1-4, 8-15) or mutated (M1 mutation, lanes 5-7) end-labelled PEA 3 probes as described previously[4]. For competition assays (lanes 8-15), the indicated molar excess of cold probe was incubated for 15 min at 0 °C with the *in vitro*-synthesized proteins before the addition of labelled probe. CON1, RNA synthesized from vector without insert; CON2, lysate without added RNA; COMPLEX, specific retarded complex; FREE, excess unretarded probe; COMP, competitor. Similar results were obtained with lysates primed with RNA transcribed by SP6 from different promoter-template combinations (data not shown).

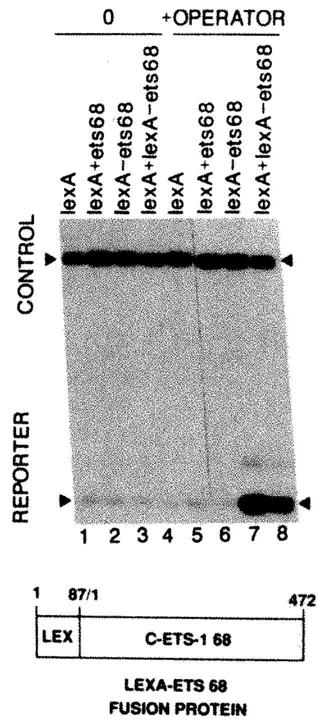

FIG. 3 The p68$^{c\text{-}ets\text{-}1}$ protein activates transcription when fused to the LexA DNA-binding domain through the *lexA* operator. LMTK$^-$ cells were transfected with 1 μg reporter recombinant containing either the *lexA* operator (lanes 5–8) or no insert (lanes 1–4), 0.5 μg internal control (pβCB × 2, ref. 4) and 1 μg expression vectors that encode either a LexA DNA-binding domain c-Ets-1 68 fusion protein (lanes 3, 7; the expression vector codes for a fusion protein containing LexA amino acids 1–87 and c-Ets-1 amino acids 1–472; bottom), or the LexA DNA-binding domain alone (lanes 1, 5), or separately for the LexA DNA-binding domain and p68$^{c\text{-}ets\text{-}1}$ (lanes 2, 6), or separately for the LexA DNA-binding domain and the LexA-Ets fusion protein (lanes 4, 8).

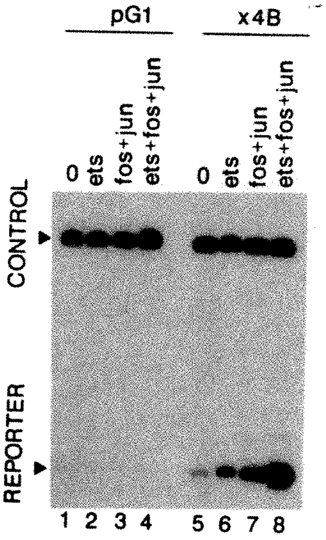

FIG. 4 Complementation between p68$^{c\text{-}ets\text{-}1}$ and c-Fos and c-Jun (AP-1) for transcriptional activation through the oncogene-responsive domain. LMTK$^-$ fibroblasts were transfected in low serum concentrations (0.05% FCS) with 1 μg reporter recombinants containing either four copies of the B mutant (lanes 5–8) or no (lanes 1–4) insert, 0.5 μg internal control (pβCB × 2) and 0.1 μg expression vectors for c-Ets-1 68, c-Fos or c-Jun[4] as indicated. Total RNA was analysed by quantitative S1 nuclease analysis. Reporter and control indicate the corresponding specific bands.

(see pG1, Fig. 1*c*, lanes 1 and 8). Similar results were obtained with a monomeric oncogene-responsive domain (data not shown). These observations could be explained by a squelching-type mechanism, in which p68$^{c\text{-}ets\text{-}1}$ specifically binds to AP-1; but other mechanisms cannot be excluded at present.

Expression of p54$^{c\text{-}ets\text{-}1}$, which differs from p68$^{c\text{-}ets\text{-}1}$ at its N terminus[10], activated transcription through the PEA 3 motif (Fig. 1*b*, lanes 1 and 4, and results not shown). The p54$^{c\text{-}ets\text{-}1}$ protein specifically bound to the PEA 3 motif (Fig. 2, lanes 2, 6, and data not shown). Therefore, the sequence differences between p68 and p54 do not significantly affect their ability to activate transcription in the systems tested.

Expression of p58-64$^{c\text{-}ets\text{-}2}$, another member of the *ets* gene family[11], activated transcription through the PEA 3 motif to a similar extent as expression of p68$^{c\text{-}ets\text{-}1}$ (Fig. 1*b*, lanes 8, 9 and 11, 12). These results indicate that the domains conserved between c-Ets-1 and c-Ets-2 are required for transcriptional activation.

The c-Ets proteins have DNA-binding and transcriptional activation domains. It seems likely that the DNA-binding domain is located in the C-terminal part of the protein that is basic, highly conserved between different *ets* gene family members[10–15] and involved in nonspecific DNA-interactions[16–20]. DNA-binding domains are highly conserved in other families of transcription factors[3,21]. Preliminary evidence indicates that the N terminus contains an activation domain (data not shown). There is no obvious homology between the *ets* family and other transcriptional activators, indicating that this is a new family of transcription factors. The oncogene-responsive domain of the Py enhancer and collagenase promoter are functionally equivalent to the type II proto-enhancer, where the association of two different motifs, which are weakly active on their own, generates a proto-enhancer, the building block of enhancers[22]. The oncogene-responsive domain represents a particular form of the type II proto-enhancer in that its activity is regulated by mitogens (and many oncogens) and it contains the motifs for three oncoprotein transcription factors. It is of interest that associated PEA 3 and AP-1 motifs are found in several oncogene-responsive promoters of the genes for stromelysin, interleukin-2, Fos and JE (see ref. 4 for discussion). The importance of *ets* and *fos* and *jun* in mediating transcriptional activation and transformation by non-nuclear oncogenes remains to be established. ☐

We thank the CNRS, INSERM, ARC, FNCLCC and Institut Pasteur de Lille for financial support.

The candidate Wilms' tumour gene is involved in genitourinary development

WILMS' tumour is an embryonic kidney tumour thought to arise through aberrant mesenchymal stem cell differentiation[1] and to result from loss of function of a 'tumour suppressor' gene(s)[2]. Both sporadic and syndrome-associated Wilms' tumours are accompanied by an increased frequency of abnormalities of the urinary tract and genitalia[3]. Deletional analysis of individuals with the WAGR syndrome[4-8] (for, Wilms' tumour, aniridia, genitourinary abnormalities and mental retardation) showed that a Wilms' tumour gene lies at chromosomal position 11p13. This led to the isolation of a candidate Wilms' tumour gene[9,10], encoding a zinc-finger protein which is likely to be a transcription factor. To gain insight into the role of this candidate gene in normal development and tumorigenesis, we have now performed *in situ* messenger RNA hybridization on sections of human embryos and Wilms' tumours. The candidate Wilms' tumour gene is expressed specifically in the condensed mesenchyme, renal vesicle and glomerular epithelium of the developing kidney, in the related mesonephric glomeruli and in cells approximating these structures in tumours. The other main sites of expression are the genital ridge, fetal gonad and mesothelium. These data suggest that (1) this candidate is indeed a Wilms' tumour gene, (2) the associated genital abnormalities are pleiotropic effects of mutation in the Wilms' tumour gene itself, in support of recent genetic analysis[11], and (3) this gene has a specific role in kidney development and a wider role in mesenchymal–epithelial transitions.

We have investigated the expression of the candidate Wilms' tumour gene by northern blot analysis and by *in situ* hybridization. For this we used the complementary DNA probe *WT2-1*, known to detect a transcript of ~3 kilobases (kb) in fetal kidney and spleen[9]. Northern analysis (Fig. 1) showed that this probe detected a 3.2-kb transcript not only in fetal kidney and spleen but also in fetal testis and ovary, with an additional 2.7-kb transcript detectable in fetal testis. There was very weak expression in fetal brain. No expression was detected in fetal heart, skin, adrenal, stomach, liver, eye or muscle.

In situ mRNA hybridization was first carried out on 18-week-gestation human kidney, chosen because it includes all stages of nephron development from uninduced blast cells at the periphery to functioning nephrons towards the centre. This full range of stages is seen because the process of kidney development, involving a reciprocal inductive interaction between the ureteric bud and the metanephric blastema, is continuous from 6-34-weeks gestation[12,13]. If the candidate gene (*WT2-1*) is involved in the initiation of Wilms' tumour, then, to explain tumour histogenesis we should expect to find it expressed in the multipotent blast cells of the kidney.

The *WT2-1* gene was expressed in a very specific manner within the developing nephron (Fig. 2*a*). Expression was weak in the condensing blastemal cells, stronger in the renal vesicle—an epithelial structure arising from the condensate—and then restricted to the maturing renal corpuscle. Here, expression was particularly strong in the developing podocyte cells of the glomerular epithelium, but, as the corpuscle matured, expression declined. By contrast, no expression could be seen in the remainder of the nephron (the proximal and distal tubules and loops of Henlé) or in the derivatives of the ureteric bud (the ureter and collecting tubules). A similar but much less intense pattern of glomerular labelling was seen in normal kidney adjacent to a Wilms' tumour removed from a 10-month-old male (data not shown).

To investigate whether the gene has a role in earlier development, we examined sections of 6-7-week human embryos by *in situ* mRNA hybridization (Fig. 2*b*). Here, *WT2-1* expression in the metanephric blastema matched that in the 18-week kidney; it was very strong in the condensing blast cells, but absent in the uninduced mesenchyme and ureteric bud branches. The *WT2-1* gene was also expressed in the glomerular epithelium of the related mesonephros and in the developing gonad, mainly over the germinal epithelium and the sex cords, but not over those germ cells that could be identified morphologically. Of the remaining tissues that could be seen clearly, expression was restricted to the mesothelial lining of the coelomic cavity and its contents, with some expression in the somatopleuric mesoderm immediately underlying this layer dorsolaterally.

If *WT2-1* plays a primary role in Wilms' tumour, we would expect mutations affecting this gene to be present in a significant number of tumours, although perhaps not in all, as more than one locus has been implicated in the disease[14-17]. We analysed 13 tumours by northern blot (Fig. 3) and found that each expressed the 3.2-kb transcript. This result is not unexpected in the light of retinoblastoma observations, where most fresh

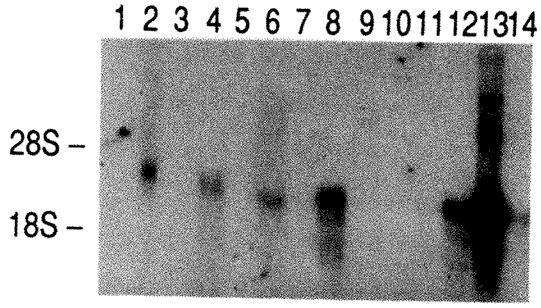

FIG. 1 Northern blot analysis of *WT2-1* expression in human fetal tissues. Lanes: 1, adrenal; 2, kidney; 3, heart; 4, ovary; 5, skin; 6, spleen; 7, stomach; 8, testis; 9, eye; 10, liver; 11, brain; 12, HEK1; 13, kidney; 14, 293 cells. Lanes 1–7, total RNA; and 8–14, poly(A)$^+$ RNA. HEK1 is a primary culture of human fetal kidney cells. 293 is an adenovirus-transformed human embryonic kidney cell line (ATCC number: CRL 1573). A 3.2-kb transcript is present in fetal kidney, spleen, testis, ovary and brain, with an additional 2.7-kb transcript seen in testis when poly(A)$^+$ RNA is used. In this experiment the RNAs ran on a slant, but we have confirmed in independent analyses that the 3.2-kb transcript is the same size in all positive tissues. Size markers shown (left).

METHODS. Human fetal tissues were obtained at autopsy of 10–19-week gestation fetuses. RNA was prepared from frozen tissues by the guanidine isothiocyanate/cesium chloride gradient method[24]. Total RNA (20 μg) or poly(A)$^+$ RNA (10 μg) was loaded, electrophoresed through 1% agarose-formaldehyde gels and transferred to Hybond-N, as described[25]. Filters were probed with *WT2-1*, a 1.5-kb *Eco*RI-*Pst*I fragment of cDNA 2-1. This was isolated from a human fetal kidney cDNA library by screening with the conserved single copy probe J803p4, which maps to the Wilms' tumour locus at 11p13 (ref. 9). High-specific-activity ^{32}P-labelled DNA probes were prepared for northern blot hybridization using a Random Prime kit according to manufacturers' instructions (Boehringer-Mannheim). Hybridization was at 68 °C in 7% SDS, 0.5 M sodium hydrogen phosphate, 1 mM EDTA. Filters were washed at 68 °C in 2×SSC, 0.1% SDS and exposed to Kodak XAR film for 18 h. Loadings were standardized by reprobing with actin (data not shown).

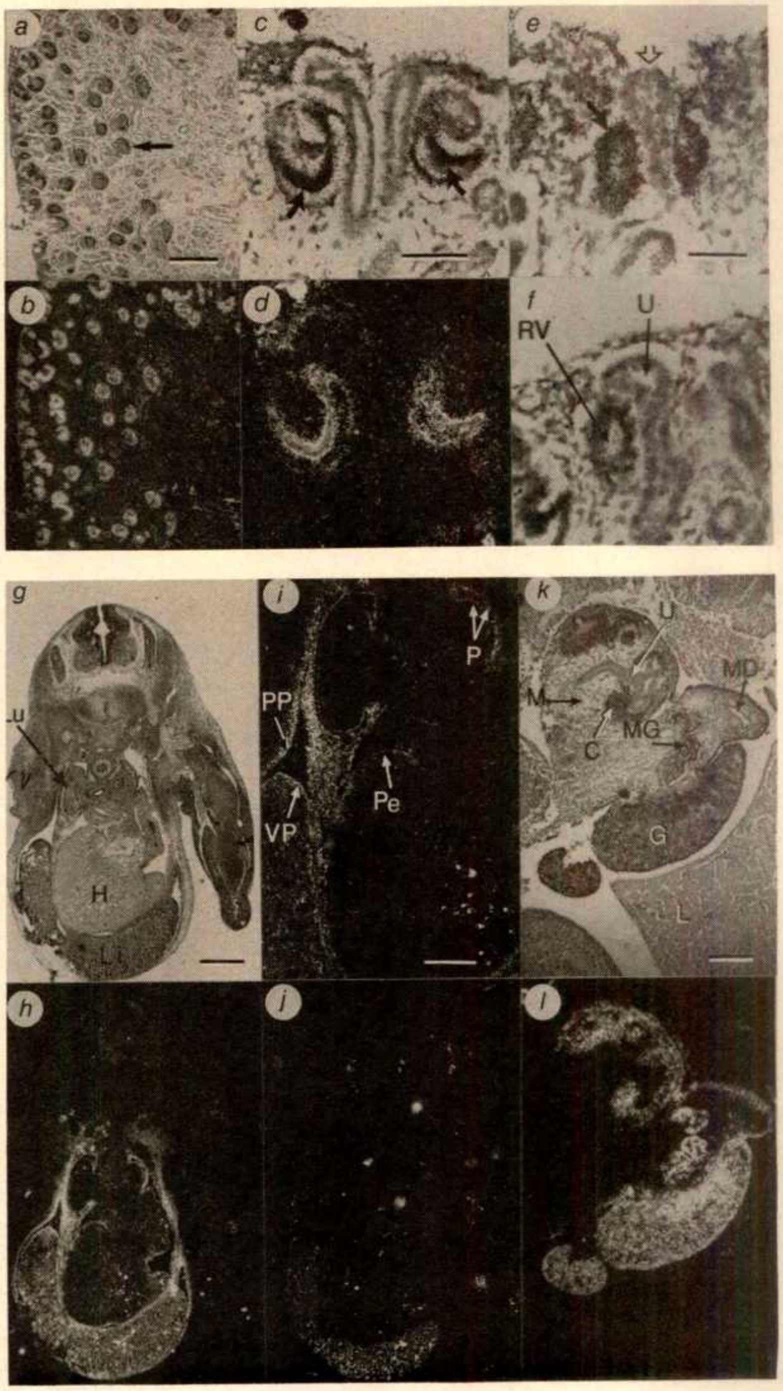

FIG. 2 *a–f*, Expression pattern of *WT2-1* in an 18-week gestation human fetal kidney as revealed by *in situ* mRNA hybridization. All stages of nephrogenesis (see refs 12 and 13 for reviews) are shown. The active nephrogenic zone is most peripheral. *a*, Low power view of longitudinal section of kidney, hybridized with antisense probe. Labelling is restricted to the subcortical condensed blastema, renal vesicle and podocyte layer of the renal corpuscle. More mature corpuscles (arrow) lie farthest from the cortex and label less strongly. Bar, 1 mm. *c*, High power view of *a* showing labelling confined to the presumptive podocyte layers (arrow) of the S-shaped body (right) and immature glomerulus (left). Bar, 200 μm. *b* and *d*, Dark-field view of *a* and *c*, respectively. *e*, High-power view of *a* showing uniformly labelled renal vesicle (arrow) adjacent to its inducing ureteric bud ampulla (hollow arrow), which does not label. Bar, 100 μm. *f*, Similar structure to *e* from adjacent section of same kidney hybridized to sense (control) probe. RV, renal vesicle; U, ureteric bud ampulla. *g–l*, Expression pattern of *WT2-1* in human embryos, as revealed by *in situ* mRNA hybridization. *g*, Transverse section through upper thoracic region of a 43-day human embryo, hybridized with antisense riboprobe for *WT2-1*. Bright field reveals structure only. Lu, lung bud; H, heart; Li, liver. Bar, 0.5 mm. *h*, Same section viewed under dark field illumination to reveal silver grains showing sites of binding of *WT2-1*. Labelling of the liver parenchyma is nonspecific as it also occurs with the control (sense) probe. *i*, Higher-power view of *h* showing labelling of pleural, peritoneal and pericardial layers. Pe, pericardium; PP, parietal peritoneum; VP, visceral peritoneum; P indicates both pleural layers. Bar, 200 μm. *j*, Adjacent section to *g* labelled with sense *WT2-1* riboprobe. Liver binding is nonspecific. *k*, Transverse section through lower abdominal region of a 49-day gestation human embryo, labelled with antisense *WT2-1* riboprobe. Heavy labelling is seen over the gonadal ridge (G), condensed metanephric blastema (C), glomerular structures of the mesonephros (MG) and the epithelial layer lining the coelomic cavity. The mesonephric duct (MD), ureteric bud branches (U) and uncondensed metanephric mesenchyme (M) are unlabelled. An adjacent section hybridized with the sense probe showed no labelling (data not shown). Bar, 200 μm. *l*, Same section as *k* viewed under dark-field illumination.

METHODS. Fetal kidneys were obtained at autopsy and embryos were obtained following legal termination of pregnancy. Specimens were fixed in 4% paraformaldehyde and wax-embedded. Sections (7 μm) were mounted onto TESPA-coated slides. *In situ* hybridization was performed as described[26], including hybridization at 55 °C in 50% formamide, high stringency washes at 65 °C in 50% formamide and RNase A treatment. Antisense and sense (control) riboprobes for the *WT2-1* gene were prepared by [^{35}S] UTP incorporation; 1.2×10^6 d.p.m. were applied to each section. In all experiments, the sense probe was routinely included and gave no labelling above background.

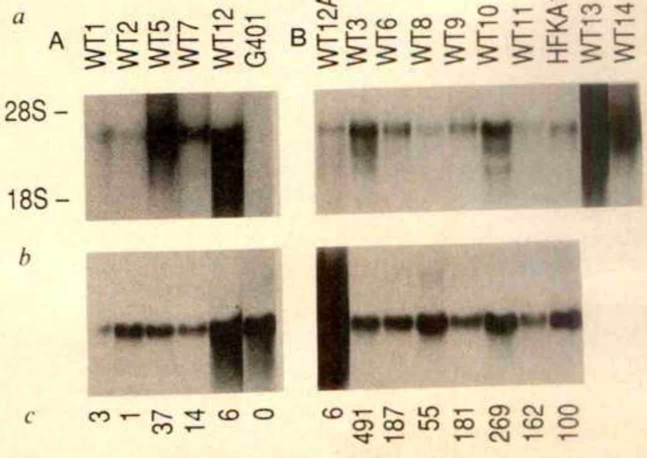

FIG. 3 Northern blot showing variation in level of *WT2-1* expression in Wilms' tumours. The same filters were hybridized to *WT2-1* (*a*) or glyceraldehyde phosphate dehydrogenase[27] (*b*) (autoradiographs were exposed for 48 h (A) and 5 h (B)). WT13 and 14 were run separately and exposed for 36 h. G401, Wilms' tumour cell line. Autoradiographs were scanned densitometrically[28] and the level of *WT2-1* expression relative to that of human fetal kidney (100%) is shown in *c*, using GAPDH to standardize loadings. Methods as in Fig. 1, but filters were washed in 0.5 × SSC.

tumour samples express a full-length transcript of the retinoblastoma gene[18], mutations only being revealed by methods detecting point mutations or small rearrangements[19]. We did, however, find an almost 500-fold variation in *WT2-1* expression, an observation that prompted us to try to correlate retrospectively expression with tumour histology. We found that tumours that were predominantly blastemal or showed epithelial differentiation expressed high levels of *WT2-1*, but tumours with stromal predominance had low levels. This correlation was confirmed directly by *in situ* mRNA hybridization analysis of seven Wilms' tumours (Fig. 4); highest levels of expression were found in tubular structures at a stage immunohistochemically equivalent to the early renal vesicle in normal development, while blastemal cells showed lower levels of expression but were clearly positive relative to the nonexpressing stromal cells. Thus, *WT2-1* expression is found only in the malignant counterparts of cell types that express the gene during normal kidney development.

Our results, taken together with the now precisely known chromosomal localization of the gene and its structural homologies[9,10], strengthen the case for *WT2-1* being a Wilms' tumour gene. The specific expression pattern of *WT2-1* contrasts with the behaviour of the retinoblastoma gene—a putative cell-cycle regulator—which is ubiquitously expressed, but gives rise through unknown mechanisms to tumours that are tissue-restricted[20]. As to the origins of Wilms' tumour, our observations lead us to the following hypothesis. During normal kidney development, the *WT2-1* gene product acts as a transcriptional regulator to switch off genes involved in maintaining cell proliferation and/or switch on genes involved in blastemal differentiation. In tumours, we suggest that the gene retains its responsiveness to its upstream regulators in the proliferative response pathway, so that it is transcribed in the appropriate cell types, but that mutation alters the ability of its product to regulate downstream target gene(s), so leading to uncontrolled proliferation with aberrant differentiation and eventual tumour formation.

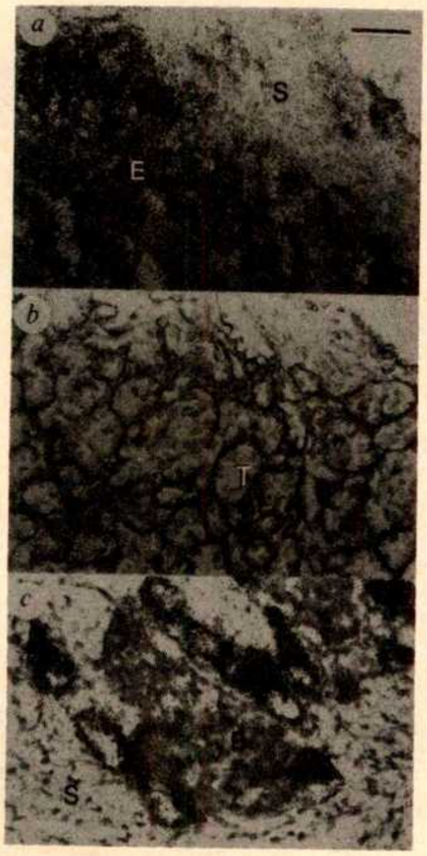

FIG. 4 Expression pattern of *WT2-1* in Wilms' tumours WT13 and 14 as shown by *in situ* mRNA hybridization. *a*, WT13 hybridized with antisense probe. There is heavy labelling over areas of epithelial differentiation (E) but none over stromal areas (S). Bar, 100 μm. *b*, Similar area in nearby section of same tumour, labelled immunocytochemically with antibodies to laminin, showing polarized basement membranes of tubular structures. Antibodies to collagen IV gave a similar result. These tubules were negative for cytokeratins 8 and 18 on an adjacent section labelled with CAM 5.2, suggesting that they are at a stage equivalent to the early renal vesicle in normal development[29,30] and not the mature tubule. *c*, WT14 hybridized with antisense probe. Labelling is seen over blastemal cells (B) and tubular structures (T) but not over the stroma (S). Similar patterns of expression were seen in five other Wilms' tumours (data not shown).

METHODS. Tumours were obtained fresh at the time of nephrectomy. Tissue fixation and *in situ* hybridization were performed as described in Fig. 2. Immunohistochemical staining was performed using polyclonal rabbit anti-laminin antibodies (Eurodiagnostics) at a 1 in 50 dilution by the peroxidase–antiperoxidase method, as described[31].

The observations presented here also cast light on other aspects of phenomena associated with normal and abnormal kidney development. The fact that the gene is expressed in both the podocytes and the more primitive mesonephros argues for it playing an important part in the development of the specialized filtration function of the kidney, a role that may have evolved early in vertebrate evolution. More intriguing, perhaps, is the observation that the gene is expressed in three tissues undergoing the rare transition from mesenchyme to epithelium: the differentiation of the metanephric mesenchyme to nephrons, the formation of the mesothelium from the mesenchyme lining the coelom and the production of sex cords from the mesenchyme of the primitive gonad. It will be interesting to investigate whether tumours from these tissues express the *WT2-1* gene.

The expression of *WT2-1* in the developing gonad gives a molecular basis for several phenomena seen in individuals with Wilms' tumour. First, the genital abnormalities seen as part of the WAGR syndrome and associated with sporadic Wilms' tumour could be pleiotropic effects of mutation in the Wilms' tumour gene. Second, both the pseudohermaphroditism and nephropathy seen as part of the Wilms' tumour-associated Drash syndrome[21] could be accounted for by disruption of a single gene. Finally, the lack of inheritance of Wilms' tumour-predisposing mutations at the 11p13 locus[14,15] could be due to such mutations causing infertility. This speculation arises from our observation of *WT2-1* expression in non-germ-cell components of the fetal gonad, from which develop the epithelial components of both testis and ovary. In abnormalities of gonadal epithelial development, both gametogenesis and the hormone-dependent development of the external genitalia may be faulty[22]. Thus, both infertility and anatomical abnormalities of the genitalia could result from mutation or reduced dosage of this gene, perhaps in a manner analogous to that described for testis determination.[23]. □

ACKNOWLEDGEMENTS. We thank Dr E. Simpson, Mr A. Azmy and Mr R. Carachi (Royal Hospital for Sick Children, Glasgow) and Drs A. Pearson, A. Craft and A. Malcolm (Royal Victoria Infirmary, Newcastle) for the provision of Wilms' tumour tissue, Dr L. Wong (MRC Fetal Tissue Bank), Professor D. Baird and Dr R. Evans for fetal tissues and early embryos and Drs J. Cowell, J. Pritchard (Institute of Child Health, London), J. Scott and C. Graham for Wilms' tumour RNAs. We also thank E. Graham, A. Ross, A. Seawright and S. Christie for expert technical assistance, N. Davidson, D. Stuart and S. Bruce for photographic work, Dr D. Green for densitometric scanning and Professor H. J. Evans for his encouragement and support. K.P.-J. is an MRC Recombinant DNA Training Fellow.

Analysis of gain-of-function mutations of the *lin-12* gene of *Caenorhabditis elegans*

Iva Greenwald & Geraldine Seydoux

Department of Biology, Princeton University, Princeton,
New Jersey 08540, USA

CERTAIN cell fate decisions are specified by cell–cell interactions during the development of the nematode *Caenorhabditis elegans*. For example, in a wild-type hermaphrodite gonad, two cells, Z1.ppp and Z4.aaa, have the potential to become the anchor cell (AC)[1]. Intercellular communication establishes their fates and ensures that only one cell becomes the AC, while the other becomes a ventral uterine precursor cell (VU)[2,3]. One component of this intercellular communication seems to be the 'AC-to-VU' signal from the presumptive AC that causes the other cell to become a VU[3]. Genetic and developmental studies[3,4] indicate that the *lin-12* gene specifies the fates of Z1.ppp and Z4.aaa. Molecular studies[5,6] suggest that *lin-12* directly participates in their communications, perhaps acting as the receptor for the 'AC-to-VU' signal[3]. Here, we report the molecular lesions associated with *lin-12* gain-of-function mutations, cell isolation experiments, and genetic studies of an unusual *lin-12* allele. These data suggest that self-association of the putative *lin-12*-encoded receptor leads to its activation, and that certain gain-of-function mutations result in ligand-independent activation.

Whereas *lin-12(0)* mutations are recessive and eliminate *lin-12* activity, causing both Z1.ppp and Z4.aaa to become ACs, *lin-12(d)* mutations are semidominant and cause both Z1.ppp and Z4.aaa to become VUs[4]: By genetic criteria, *lin-12(d)* mutations behave like hypermorphic (elevated activity) mutations[7]: addition of *lin-12(+)* alleles to a *lin-12(d)* mutation increases the proportion of hermaphrodites that show the transformation of the presumptive AC into a VU. So elevated *lin-12* activity is sufficient to cause expression of the VU fate. To explore how *lin-12(d)* mutations elevate *lin-12* activity, we identified the molecular lesions associated with *lin-12(d)* mutations. We analysed a 13.8 kilobase (kb) genomic region comprising the coding and flanking regions by denaturation gradient gel electrophoresis[8,9] of DNA amplified by the polymerase chain reaction (PCR; see Fig. 1 legend), and direct sequencing[10]. All of the *lin-12(d)* mutations are missense alterations of the putative extracellular region of the protein (Fig. 1). Five different mutations alter the extracellular cysteine-poor region of the protein; two others alter one of the adjacent cysteine-rich motifs (see Fig. 1). Although the mutations have nothing obvious in common, it is curious that the *n137*, *n177* and *n950*, the three 'strongest' alleles by gene-dosage criteria[4] (see Table 2), are located within four codons of one another. Because all eight *lin-12(d)* mutations alter the predicted protein sequence, they are likely to be modifying protein activity or stability.

To examine further how *lin-12(d)* mutations elevate *lin-12* activity, we performed laser ablation experiments on *lin-12(d)* mutants. In wild type, when all other somatic gonadal cells have been ablated, an isolated Z1.ppp or Z4.aaa becomes an AC. Expression of the VU fate by either cell requires both cells to be present, as one cell must send the 'AC-to-VU' signal to promote expression of the VU fate by the other cell[2,3]. In

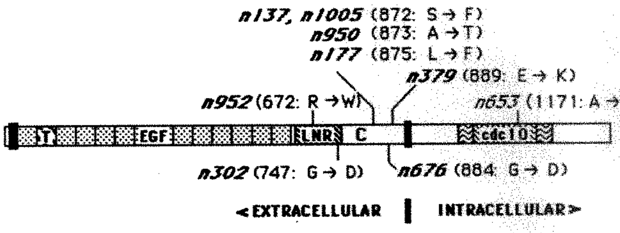

FIG. 1 Sequence alterations associated with eight *lin-12(d)* mutations and with *n653*. Predicted amino acid changes [residue number: change (single letter code)] deduced from sequence analysis of different *lin-12(d)* alleles (bold) and of the *n653* mutation, shown on a schematic depiction of the *lin-12* product[6]. EGF, EGF (epidermal growth factor) like motifs; T, 'T + Y'-encoded motif; LNR, lin-12–Notch repeated motif; cdc10, cdc10/SW16 motif; C, position of a pair of cysteines that is conserved in lin-12, glp-1 and Notch; black regions represent hydrophobic stretches that might serve as a signal-sequence (amino terminus) or membrane-spanning region (internal). The nucleotide changes observed were: *n952* (9,861 C → T), *n302* (10,087 G → A), *n137* and *n1005* (10,462 C → T), *n950* (10,464 G → A), *n177* (10,470 C → T), *n676* (10,498 G → A), *n379* (10,512 G → A). All *lin-12(d)* mutations arose after ethyl methanesulphonate (EMS) mutagenesis of a *lin-12(+)* chromosome (refs 4, 23, and E. Ferguson, N. Tsung, C. Desai and R. Horvitz, personal communication); they are all transitions, as is generally the case for EMS-induced mutations. The amino acids altered by *lin-12(d)* mutations are not necessarily conserved in other genes related to *lin-12*.
METHODS. PCR was used to amplify six 2–3 kb regions of DNA from the *lin-12* locus. The region analysed was 13.8 kb, and ranged from ~2.5 kb upstream of the apparent initiation codon (nucleotide position 1,848; numbering as in Genbank entry M21478) to 100 base pairs (bp) past the region encoding the 3′ end of the messenger RNA (position 13,109, which is in the next gene, *gst-1*; ref. 21). The PCR reaction mixtures were extracted with phenol-chloroform, precipitated with ethanol, and resuspended in (10 mM Tris buffer, 1 mM EDTA. Equal amounts of wild-type and *lin-12*-mutant DNA segments generated by PCR were mixed, boiled (2 min), and allowed to renature at room temperature (15 min). Restriction buffer and appropriate restriction enzymes (that would yield fragments ranging from 200–800 bp) were added, and the reactions were incubated until digestions were complete, as ascertained by agarose gels. Denaturing gradient gel electrophoresis (DGGE) was performed as described in refs 8 and 9; typically, three different digests of each heteroduplexed DNA mixture were subjected to DGGE for 18 h at 65V (20–80% linear gradient of denaturant, formamide and urea). Because all *lin-12(d)* mutations were generated by EMS-mutagenesis of the isogenic strain N2 (ref. 22), alterations revealed by DGGE were likely to result from the *lin-12(d)* mutations and not from strain polymorphisms. The *lin-12(d)* alleles *n379*, *n302* and *n676* were localized by DGGE to the region comprised by nucleotides 9,682–11,041; although subsequent sequence analysis revealed that the other five *lin-12(d)* mutations were located in this region, they were not detected by DGGE under the conditions that we used. This region was then amplified in all mutants and sequenced directly[10] using internal primers. No other changes were seen in any other region examined by DGGE, although not all regions were examined for every *lin-12(d)* mutation. We do not have sequence information for the region outside of 9,682–11,041, other than some spot sequencing of cloned DNAs from the region encompassed by nucleotides 11,011–13,109 (from the intracellular region of the protein) from the *lin-12(d)* alleles *n379*, *n302*, *n676*, *n952* and *n137*. The alteration associated with the *n653* mutation creates an *Rsa*I site and was recognized by agarose gel electrophoresis of *Rsa*I-digested amplified DNA from the region comprised by 11,011–13,109. The presence of the *n302* mutation in *lin-12(n302 n653)* was confirmed by sequence analysis of amplified DNA from 9,682–11,041. We examined the entire 13.8-kb region encompassing the coding and flanking regions of *lin-12(n302 n653)* by DGGE and found no other alterations or restriction site polymorphisms. The *n653* mutation results in a conservative Ala → Val change; this Ala is present in corresponding positions in both glp-1 (ref. 16) and Notch (refs 13, 14).

TABLE 1 Ablation of all gonadal cells except Z1.ppp or Z4.aaa in *lin-12(d)* mutants

lin-12 genotype[*]	*n*[†]	Fate[‡] of Z1.ppp or Z4.aaa
+	5/5[§]	AC
n379	3/3	VU
n349	4/4	VU
n676	4/4	VU
n952	7/7	VU
n137	8/8[‖]	VU

Ablations were performed as described in ref. 3.

[*] Complete genotypes: *n379* is *lin-12(n379); him-5(el1467). n952* is *unc-32(e189) lin-12(n952). n137* is *lin-12(n137); him-5(e1467).*

[†] *n*, Number of animals that exhibited the cell fate indicated divided by the total number of animals examined.

[‡] AC, anchor cell; VU, ventral uterine precursor cell. Criteria for scoring cell fates were as described[3].

[§] Data from refs 1 and 3.

[‖] Data from ref. 3.

contrast, in all five *lin-12(d)* mutants examined, an isolated Z1.ppp or Z4.aaa expresses the VU fate (Table 1)[3]. These results suggest that *lin-12(d)* protein is active in the absence of the 'AC-to-VU' signal, is capable of autocrine activation by the signal produced by the isolated cell, or is capable of activation by low levels of the signal present in cellular debris. These results imply not only a functional difference between *lin-12(d)* and *lin-12(+)* proteins, but also a functional similarity among the *lin-12(d)* proteins, because all *lin-12(d)* alleles behave the same way by this laser ablation criterion.

We next analysed the behaviour of *lin-12(d)* mutations in heteroallelic combinations with the *lin-12(n302 n653)* allele (Table 2), which is associated with two point mutations. One, *n302*, is a *lin-12(d)* mutation in the putative extracellular domain; the other, *n653*, is in the putative intracellular domain (see Fig. 1 and Table 2). The phenotype of *lin-12(n302 n653)* homozygotes at 25 °C suggests that *lin-12* activity is strongly reduced: *lin-12(n302 n653)* homozygotes have two ACs (Table 2) as do *lin-12(0)* hermaphrodites. As expected for an allele that reduces *lin-12* activity, *lin-12(n302 n653)* is completely recessive to *lin-12(+)* (Table 2), even in hermaphrodites of *lin-12* genotype *lin-12(n302 n653)/lin-12(n302 n653); mnDp37[lin-12(+)]* (data not shown). Table 2, however, demonstrates that at 25 °C *lin-12(n302 n653)* does not behave as a simple reduced-activity allele in heteroallelic combinations, that is, it does not have *lin-12* activity intermediate between that of *lin-12(+)* and *lin-12(0)*. Instead, in combination with *lin-12(d)* alleles, *lin-12(n302 n653)* seems to have greater activity than a *lin-12(+)* allele. This result suggests that a *lin-12(d)* protein can transactivate or stabilize the protein encoded by *lin-12(n302 n653)*. In addition, the degree of proposed transactivation seems to be *lin-12(d)* allele-specific: although *lin-12(n952)* seems to elevate *lin-12* activity more than *lin-12(n302)* in gene-dosage studies with *lin-12(+)* and *lin-12(0)* alleles, fewer *lin-12(n952)/lin-12(n302 n653)* hermaphrodites than *lin-12(n302)/lin-12(n302 n653)* hermaphrodites display the gain-of-function phenotype (Table 2). This apparent allele-specificity supports the interpretation of a direct association between proteins encoded by *lin-12(d)* and *lin-12(n302 n653)* and, by extension, between those encoded by *lin-12(d)*.

We can perhaps also explain how *lin-12(+)* alleles augment *lin-12(d)* activity, by proposing that a *lin-12(d)* protein can transactivate a *lin-12(+)* protein. But it remains possible that the *lin-12(+)* allele contributes a basal level of *lin-12* activity that can augment *lin-12(d)* activity.

Finally, we postulate that the *lin-12(+)* protein also self-associates to form dimers or multimers, leading to activation. Genetic evidence for self-association of the *Drosophila Notch* protein[11,12], which is similar to the *lin-12* protein in overall predicted structure[6,13,14], has recently been supported by direct biochemical evidence of dimerization[15]. In this context, it is noteworthy that the region of the *lin-12* protein affected in *lin-12(d)* mutants includes a pair of cysteines also present at a corresponding position in Notch, although the extracellular cysteine-poor regions of these two proteins do not display any other notable amino-acid similarity[6]. The two cysteines are also present in a corresponding position in the predicted protein products of other members of the *lin-12/Notch* family, including another *C. elegans* gene, *glp-1* (ref. 16), and genes from *Xenopus* (C. Coffman, C. Kintner & W. Harris, personal communication) and humans (L. Ellisen & J. Sklar, personal communication). These two cysteines—the only two in that region of the protein—may be responsible for the sulphydryl-mediated dimerization of Notch[15].

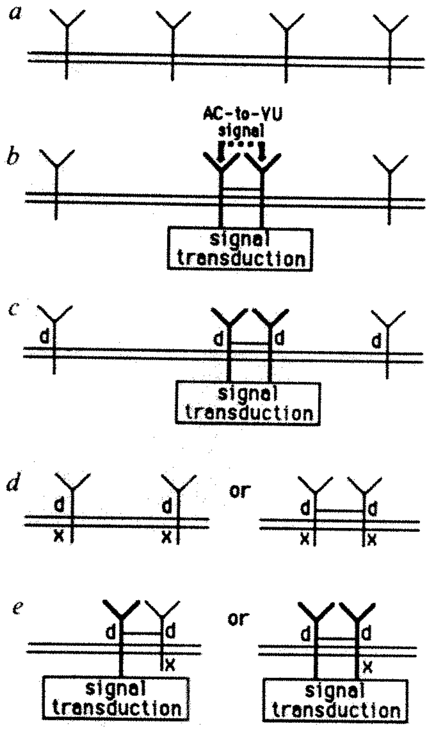

FIG. 2 A model for how dimerization leads to activation of the *lin-12* protein. *a*, In wild type, lin-12 is a receptor that is inactive in the absence of its ligand. *b*, In wild type, the ligand ('AC–VU' signal) promotes dimerization, leading to signal transduction by means of the intracellular domain. Ligand-binding to receptor monomer may cause a conformational change that results in or stabilizes dimerization; alternatively, the ligand may have a more direct role in a cross-linking mechanism. *c*, In a *lin-12(d)* homozygote, dimerization and signal transduction are ligand-independent. The *lin-12(d)* mutations might result in ligand-independent activation of the *lin-12* protein by inactivating a negative regulatory domain or by causing changes in the higher-order structure. *d*, In a *lin-12(n302 n653)* homozygote, the *n653* mutation either prevents homodimer formation or inactivates *lin-12*. *e*, In a *lin-12(d)/lin-12(n302 n653)* heterozygote, heterodimers can form and are active.

TABLE 2 Heteroallelic combinations between *lin-12(n302 n653)* and *lin-12(d)* alleles

lin-12 genotype*	Egl/total†	Percentage of Egl
+/n302 n653	0/203‡	0
n379/n302 n653	143/237	40
n379/+	38/357	11
n379/lin-12(0)	14/252	6
n302/n302 n653	226/296	76
n302/+	101/204	50
n302/lin-12(0)	36/184	20
n952/n302 n653	156/245	64
n952/+	186/299	62
n952/lin-12(0)	63/199	32
n676/n302 n653	202/214§	94
n676/+	183/260	70
n676/lin-12(0)	154/425	36
n137/n302 n653	112/112	100
n137/+	256/289	89
n137/lin-12(0)	88/190	46

All experiments were performed at 25 °C, as the behaviour of *lin-12(n302 n653)* is temperature-dependent (G.S. and I.G., unpublished observations). If the *lin-12(d)* heterozygote and hemizygote data presented here are compared with the data at 20 °C (ref. 4), the penetrance of *lin-12(n952)* and *lin-12(n137)* is lowered and that of *lin-12(n379)* is elevated. The *lin-12(n302)* hermaphrodites are egg-laying defective (Egl), a direct consequence of the transformation of the presumptive AC into a VU[4]. Because the penetrance of the Egl defect is incomplete in *lin-12(d)/lin-12(0)* and *lin-12(d)/lin-12(+)*, wild-type (non-Egl) revertants containing alleles that lower the activity of *lin-12(n302)* may be obtained. The most common intragenic revertant class obtained after ethyl methanesulphonate mutagenesis comprises *lin-12(0)* alleles[4]; *lin-12(n302 n653)* is one of a heterogeneous class of non-null revertant alleles (I.G., unpublished observations). At 25 °C, in the dissecting microscope, *lin-12(n302 n653)* homozygotes all have 2AC (52/52), so it resembles a *lin-12(0)* allele for the AC/VU decision. But *lin-12(n302 n653)* seems to retain some *lin-12* activity: only 52% (71/136) have the characteristic Lin-12(0) ventral protrusion; the remainder have a smaller vulval protrusion. The *lin-12(n302 n653)/lin-12(0)* hermaphrodites resemble *lin-12(n302 n653)* homozygotes.

* We represent here a marker linked to *lin-12* as '*mar*'. Total non-Mar non-Unc self-progeny were counted from heterozygotes of genotype *mar lin-12(d)/unc-36(e251) lin-12(n302 n653); him-5(el467)/+*, *mar lin-12(d)/unc-36(e251); him-5(el467)/+*, or *mar lin-12(d)/unc-36(e251) lin-12(n137 e2034::Tcl); him-5(el467)/+*. For *n379, n302* and *n676, mar* is *dpy-17(e164)*; for *n952, mar* is *unc-32(e189)*; for *n137, mar* is *dpy-19(e1259)*. *lin-12(n137 e2034::Tcl)* is a *lin-12(0)* mutation.

† *Egl*, number of hermaphrodites that display an Egl defect associated with elevated *lin-12* activity (the AC/VU cell fate transformation)[4]. To verify that *lin-12(d)/lin-12(n302 n653)* hermaphrodites displayed this transformation, we examined the progeny of *unc-36(e251) lin-12(n302 n653)/dpy-17(e164) lin-12(n379); him-5(e1467)/+* hermaphrodites in the L3 stage for the presence of an AC: 16/37 (43%) hermaphrodites did not have an AC, and 6/6 of these hermaphrodites were Egl; 21/37 hermaphrodites had one AC, and 7/7 of these hermaphrodites were non-Egl.

‡ 2/203 *unc-36(e251) lin-12(n302 n653)/++* hermaphrodites had an abnormal vulva that affected egg-laying, but the abnormality was not of the sort associated with elevated *lin-12* activity.

§ The *lin-12(n676)* homozygotes, heterozygotes and hemizygotes display the AC to VU transformation but rarely display a 'multivulva' (Muv) phenotype, which is caused by transformation of the vulval precursor cell fates[4]. The 'strong' *lin-12(d)* mutants *lin-12(n950)*, *lin-12(n137)* and *lin-12(n177)* display a Muv phenotype as homozygotes, heterozygotes and hemizygotes; *lin-12(n952)* mutants display a Muv phenotype only as homozygotes. It is therefore striking that most *lin-12(n676)/lin-12(n302 n653)* hermaphrodites displayed a Muv phenotype; the lineages of the vulval precursor cells were not determined.

We incorporate the genetic and molecular findings reported here into our receptor model for *lin-12* function[3] (Fig. 2). According to this model, *lin-12* encodes a receptor that becomes activated on binding of its ligand. The ligand activates the *lin-12* protein by promoting its self-association, and on activation, the intracellular domain induces signal transduction. This model is plausible in view of what is known about biochemically defined receptors. In many cases, the association state of receptors in the membrane controls their activity, and association state is in turn controlled by ligand-binding[17-20]. Although the available data are consistent with the model proposed here, other interpretations are possible. Thus, a future challenge will be to obtain biochemical evidence to confirm or disprove this model. ☐

RNA-polymerase specificity of transcription of *Arabidopsis* U snRNA genes determined by promoter element spacing

Franz Waibel & Witold Filipowicz

Friedrich Miescher-Institut, PO Box 2543, 4002 Basel, Switzerland

ALTHOUGH most eukaryotic genes known to be transcribed by RNA polymerase III have intragenic promoter elements, some are similar to genes transcribed by RNA polymerase II in that they have upstream promoters (reviewed in refs 1–4). Transcription of the vertebrate U6 and 7SK RNA genes by RNA polymerase III depends exclusively upon upstream signals, some of which are indistinguishable from the elements essential for polymerase II-specific genes[5-11]. In the plant *Arabidopsis thaliana* the promoter elements for the U6 and U2 small nuclear RNA genes, transcribed by RNA polymerases III and II respectively, are identical, comprising a −30 TATA box and an upstream element specific for small nuclear RNA genes[12,13]. The distance between these elements differs, however. Here we report evidence that this separation is crucial in determining whether the genes are transcribed by polymerase II or III.

Figure 1 illustrates the organization of the upstream promoter elements for the plant U small nuclear (sn) RNA genes transcribed by RNA polymerases II and III (pol II and pol III). In pol II-specific genes the upstream sequence element (USE) and the TATA-like box are centred roughly four DNA helical turns apart, whereas in pol III U6 genes the spacing is about one helical turn less. Hybrid U snRNA genes were prepared to

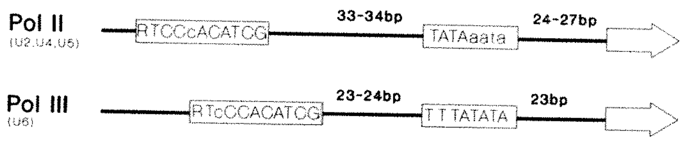

FIG. 1 Conserved upstream elements of pol II- and pol III-transcribed U snRNA genes of *Arabidopsis*. The pol II consensus is based on the sequences of six U2 (ref. 18), one U4 (our unpublished results) and one U5 gene[15]; U1 RNA genes isolated from bean, soybean and tomato contain the same conserved elements at similar positions[21,22]. The pol III consensus is based on the sequences of three active U6 genes (F. W. and W. F., manuscript submitted). Elements found in both pol II and pol III promoters are boxed. Nucleotides not conserved in all genes are in lower case. The coding region is indicated by an arrow. For both U2 and U6 genes of *Arabidopsis* the USE and TATA seem to be the only essential promoter elements and the TATA elements of U2 and U6 genes are exchangeable. The evidence that U2, U4 and U5 genes are pol II-specific is based on the presence of m_3G caps in the RNA products and on the sensitivity of transcription in protoplasts to α-amanitin. Transcription of the U6 genes is resistant to α-amanitin and terminates within stretches of T residues, which function as pol III terminators[12,13].

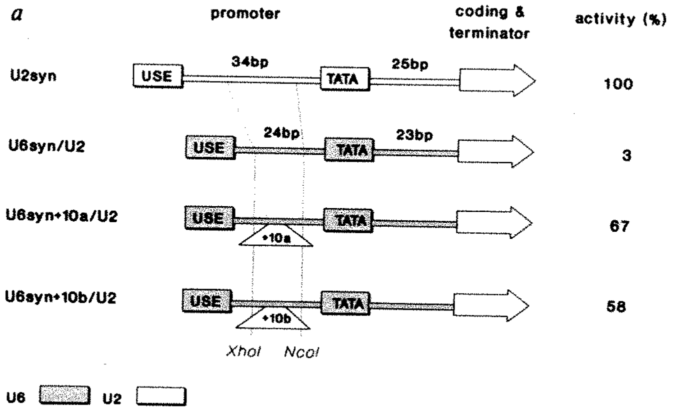
examine whether a pol III promoter can be converted into a pol II promoter and vice versa, by changing the distance between the elements. In the construct U6syn/U2 (Fig. 2*a*) the promoter of the model U6syn gene was fused with an *Arabidopsis* U2 gene lacking its own promoter[12]. The resulting gene contains a 70-base-pair (bp) U6syn promoter followed by 196 bp of the coding and 264 bp of the downstream noncoding U2 gene sequence. Transfection of the hybrid U6syn/U2 gene into protoplasts of *Nicotiana plumbaginifolia* resulted in accumulation of only trace levels of U2 RNA (Fig. 2*b*). This observation is not unexpected. If RNA synthesis from this construct were indeed initiated by pol III, transcription would probably terminate in the coding region of the U2 gene where stretches of T residues, which act as pol III terminators[14], are present. The accumulation of mature U2 RNA may also be prevented by the inability of pol III to terminate transcription at the U2 gene termination signal[15] or by inappropriate RNA capping[16].

We prepared two derivatives of the U6syn/U2 hybrid, U6syn+10a/U2 and U6syn+10b/U2, each having an additional 10 bp of different sequence inserted between the USE and TATA box (Fig. 2*a*). Transfection of these genes resulted in accumulation of U2 RNA at a level comparable to that seen



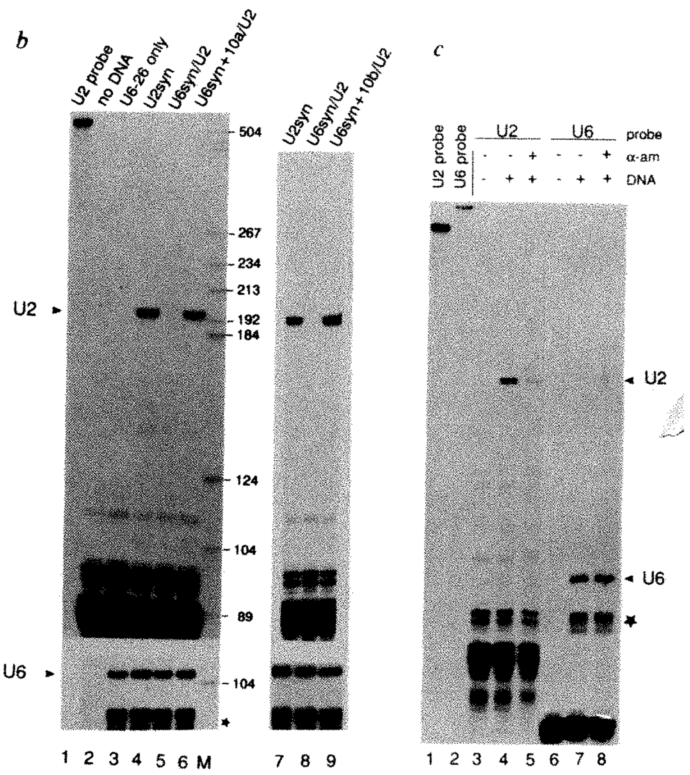


FIG. 2 Conversion of the U6 gene promoter into a pol II-specific promoter. *a*, Schematic representation of the U2syn gene and of the hybrid U6syn/U2 genes. The U2syn and U6syn gene sequences of the hybrid genes are shown as open and stippled boxes, respectively. The relative activities of the different genes are indicated (averages from three independent transfections). *b*, RNase A/T_1 mapping. Protoplasts were transfected with plasmid pU6-26 (containing reference U6 gene) alone (lane 3) or with pU6-26 plus the genes indicated above lanes 4-9. The upper and lower panels show mapping with U2 and U6 probes, respectively. Two different U2-specific probes, the wild-type U2 gene probe (lanes 4-9) and the U6syn/U2-specific probe (data not shown; these probes differ in sequences upstream of position +1) yielded identical protected fragments, indicating that initiation occurred at the A at position +1 and that transcripts were properly terminated. M, size markers (in nucleotides). The 93-97-nucleotide bands (*) result from the partial digestion of the U6 RNA-specific hybrid by RNase A at the AU-rich 3′ end. *c*, Effect of α-amanitin on expression of the gene U6syn+10a/U2. Protoplasts were cotransfected with pU6syn+10a/U2 and pU6syn and incubated in the presence or absence of 50 μg ml^{-1} α-amanitin. Mapping with U2 and U6 probes is in lanes 3-5 and 6-8, respectively.

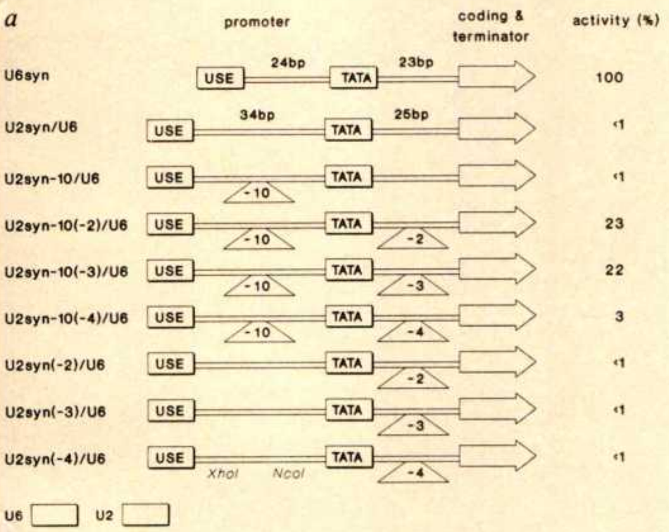
METHODS. The gene U2syn is a derivative of U2.SP, the *Arabidopsis* U2 RNA gene that contains a synthetic 98-bp promoter; pU2syn was constructed similarly to pU2.SP (ref. 12). The U2syn gene differs from U2.SP by four nucleotide substitutions in the −22 to −8 region that create *NdeI* and *AatII* sites (Fig. 3*b*). The activities of the U2.SP, U2syn and the authentic U2 gene are comparable[12]. The plasmid pU6syn/U2 was constructed similarly to pU2syn (ref. 12). The U6syn promoter sequence (position −70 to −1; see Fig. 3) was assembled from five oligonucleotides and inserted into pU2.2/ClaI (ref. 12) pre-cut with *Bam*HI and *Cla*I. Mutated constructs U6syn+10a/U2 and U6syn+10b/U2 were generated from U6syn/U2 by replacement of the *XhoI*-*NcoI* fragment with a longer linker having the sequence CTCGAGTAAAAATAAGAAAGATTCCATGG or CTCGAGTTATGGAATTTCTTCTACCATGG. Expression was tested in protoplasts of *N. plumbaginifolia*[26,27]. Subsaturating amounts (10 μg) of plasmids were used. RNA was prepared 24 h after transfection and used (3 μg) for RNase A/T_1 mapping[26,27]. The U6 and U2 gene-specific antisense RNA probes, of 440 and 510 nucleotides, were synthesized with SP6 polymerase using [$\alpha-{}^{32}$P]GTP and pU6-26 (linearized with *Bst*XI) or pGEM2.U2.2 (linearized with *Hin*dIII)[18] as templates. Protected fragments were quantitated[26,27] and activity normalized for transfection efficiency as measured by expression of the reference gene.

with the gene U2syn, in which synthesis of U2 RNA is driven by a synthetic U2 gene promoter (Fig. 2*b*). Transcription of the gene U6syn + 10a/U2 was inhibited by α-amanitin as expected[17] for a gene transcribed by pol II; transcription of the cotransfected control U6 gene was α-amanitin resistant (Fig. 2*c*). It is possible, therefore, to change the pol III-specific U6 gene promoter into an efficient pol II-specific promoter by inserting 10 bp of DNA between the USE and the TATA-like box. It should be noted that each of the inserted sequences differs substantially from the sequences present in this region in the authentic U2 genes[18].

To study the pol II to pol III promoter conversion we have constructed a hybrid gene, U2syn/U6, in which the 98-bp synthetic promoter[12] of the gene U2syn is fused with the coding and terminator regions of the gene U6syn. We also made a U2syn/U6 derivative, U2syn − 10/U6, in which the distance between the USE and TATAAATA was shortened by 10 bp to conform with the spacing in pol III-specific promoters (Fig. 3*a*). Neither of the two genes was active in synthesis of U6 RNA (Fig. 3*c*). We have noted that the distance between the TATA-like sequence and the transcription start site is 1-4 bp shorter in U6 genes as compared with the pol II-specific genes (Fig. 1) and, in particular, 2 bp shorter than in the genes U2syn/U6 or U2syn − 10/U6 (Fig. 3*b*). We have therefore prepared three variants of each of these two genes, in which the TATA to +1 distance is shortened by 2, 3 or 4 bp (Fig. 3*a* and *b*). None of the constructs of the U2syn/U6 series (U2syn (−2, −3 or −4)/U6) was active but two of the constructs containing, in addition, a 10-bp deletion between the USE and TATA, U2syn − 10(−2)/U6 and U2syn − 10(−3)/U6, yielded U6 RNA (Fig. 3 *c*). The U6 RNA synthesis from U2syn − 10(−2)/U6 (Fig. 3*d*) and U2syn − 10(−3)/U6 (data not shown) was α-amanitin-resistant as expected for genes transcribed by pol III. Hence, it is also possible to change a pol II promoter into a pol III promoter by manipulating the spacing between the USE and TATA elements, provided that the distance between the TATA-like sequence and the initiation site conforms to the U6 gene consensus.

It is unlikely that the 1-4-bp difference in the TATA to +1 distance found between pol II and pol III U snRNA genes is important for polymerase selection. The gene U6syn + 10/U2, for example, has a pol III-like TATA to +1 spacing, but is very efficiently transcribed by pol II (Fig. 2). It is more probable that pol II and pol III themselves differ slightly in the properties responsible for specifying the TATA to +1 distance. It has been demonstrated that factors other than the TATA box-binding



b

GENE	TATA/+1 DIST. (bp)	DNA SEQUENCE -10 -1 +1	
U6syn	23	TATA ATGATC--ATGTCGACATATCGATT	GTCCCTTCGG
U2syn/U6 and U2syn-10/U6	25	TATA ACTCATATGCTGGTGACGTCAATTC NdeI AatII	GTCCCTTCGG
U2syn(-2)/U6 and U2syn-10(-2)/U6	23	TATA ACTCAT**GCTGGTGACGTCAATTC	GTCCCTTCGG
U2syn(-3)/U6 and U2syn-10(-3)/U6	22	TATA ACTCA***GCTGGTGACGTCAATTC	GTCCCTTCGG

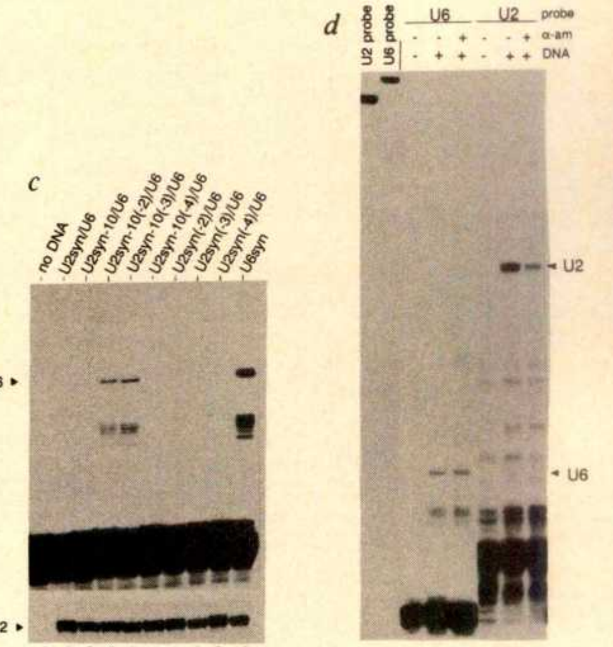

FIG. 3 Conversion of the U2 gene promoter into a pol III-specific promoter. *a*, Schematic representation of different genes and their activities (for more details see text and Fig. 2*a*). *b*, sequences of the −25 to +10 regions of the genes in (*a*). *, Nucleotides deleted in some mutated constructs. The *Nde*I and *Aat*II sites in U2syn/U6 are underlined. The distance between the TATA element (boxed) and position +1 is indicated. *c*, RNase A/T_1 mapping with U6 and U2 probes. Plasmids used for contransfection with pU2.2, which contains the reference U2 gene[12], are indicated at the top. Mapping of U6 RNAs transcribed from these plasmids was carried out with probe U6-26 (lanes 2-10), which is complementary to the upstream nucleotides in genes U6-26 and U6syn but not in genes of the U2syn/U6 series and with the probe specific for the gene U2syn/U6 (data not shown). The protected fragments were of identical lengths, indicating that initiation occurred at the G at position +1 and that transcripts were properly terminated. *d*, Effect of α-amanitin. Protoplasts were contransfected with pU2syn − 10(−2)/U6 and pU6syn. Mapping with U6 and U2 probes, lanes 3-5 and 6-8 respectively.

METHODS. The 188-bp U6syn sequence, assembled from 10 overlapping oligonucleotides, is described in detail elsewhere[13]. The 70-bp upstream region of U6syn contains the USE and TTTATATA elements at the conserved positions. The remaining upstream sequence is mostly unrelated to that of the authentic U6 genes and contains several restriction sites. The coding region is identical to the wild-type sequence and a stretch of T residues is included downstream as a terminator. The U6syn was transcribed with 60-65% efficiency compared with the authentic U6 RNA genes. The parent U2syn/U6 hybrid gene, including 98 bp of U2syn promoter (see Fig. 2) fused with the coding and terminator regions of U6syn, was prepared by annealing and ligation[26] of 11 oligonucleotides. Synthetic U6syn and U2syn/U6 fragments were inserted into plasmid pTZ19R pre-cut with *Bam*HI and *Sph*I. The variants U2syn (−2, −3 or −4)/U6 were obtained by cleavage of pU2syn/U6 with *Nde*I, followed by limited digestion with mung bean nuclease and religation. The variants having a 10-bp deletion in the USE/TATA region were obtained by replacement of the 29-bp *Xho*I-*Nco*I fragment[12] with the shorter linker CTCGAGTAAAAATCCATGG.

protein (possibly RNA polymerase itself) 'measure' this distance during transcription by pol II[19,20]. The inability of pol III to initiate transcription from the U2syn−10/U6 and U2syn−10(−4)/U6 genes may be due to the absence of a pyrimidine-purine dinucleotide located at the correct (22–23 bp) distance from the TATA box (Fig. 3*b*). Transcription of all plant U snRNA genes starts at a purine residue preceded by a pyrimidine[15,18,21,22]. Transcription of the U6 gene of *Xenopus* has similar requirements[6].

Our experiments do not formally eliminate the possibility that intragenic sequences also contribute to RNA polymerase selection. But the identification of two other pol III-specific gene classes in *Arabidopsis* having USE/TATA spacing similar to that of U6 genes (T. Kiss, Ch. Marshallsay and W. F., manuscript in preparation) and the demonstration that the intragenic A box-like sequence found in *Arabidopsis* U6 genes is not required for transcription[13] make this possibility unlikely.

The mechanism by which differences in spacing between two promoter elements in plant U snRNA genes determine the choice of RNA polymerase is not known. The mode of interaction between the proteins that bind the USE and TATA may depend on the spacing between them, giving rise to two alternative surfaces recognized by the appropriate polymerase complex or by an additional protein acting in between. Alternatively, distinct TATA or USE factors may interact with pol II and pol III promoters, specificity being governed by the proximity of the protein bound at the neighbouring site.

The structure of U snRNA gene promoters and the factors that define polymerase specificity are different in plant and vertebrate cells. Class II and class III promoters in vertebrates contain two common upstream elements, DSE and PSE, which are sufficient for transcription of the U2 gene by pol II (reviewed in refs 23, 24). The U6 genes contain an additional element, an AT-rich TATA-like box that confers pol III specificity[6,9]. In plants, both classes of U snRNA genes contain essential −30 TATA-like elements and it will be of interest to determine whether the same or different TATA factors participate in pol II- and pol III-specific transcription.

Our results support the idea that polymerases II and III evolved from a common ancestor[25], as did pol II and pol III U snRNA gene promoters[6], and that one mechanism of promoter diversification in eukaryotes involved changes in the spacing between promoter regulatory elements. ☐

The World's Number One Primary Research Journal in Pharmacology

The latest Journal Citation Reports, from the ISI's Science Citation Index,show that the British Journal of Pharmacology has now become the most intensively cited primary research pharmacology journal in the world.

To celebrate this, and to accommodate the enormous increase in high quality papers submitted in the last few years, we have increased our page size by nearly 40% to a smart new A4 format.

CALL FOR PAPERS

Announcing . . .

Molecular Neuropharmacology

Edited by **G.N. Woodruff** with the assistance of an international editorial board.

Aims and scope: This new journal will publish the results of investigations that contribute to the understanding of molecular aspects of drug action in the central and peripheral nervous systems. New data on the molecular basis of the actions of therapeutically-active drugs will be particularly welcome. Other areas of interest include the mechanisms of action of neurotransmitters and other drugs in terms of the structure and function of receptors, enzymes, ion channels and second messenger systems.

Papers should be prepared in accordance with the current instructions to authors for the British Journal of Pharmacology and submitted to the editor at the following address:

Dr. G.N. Woodruff, Molecular Neuropharmacology, Parke-Davis Research Unit,
Addenbrookes Hospital Site, Hills Road, Cambridge , CB2 2QD , UK

Frequency: To be published initially as four issues per volume. ISSN 0959–5244

Prices (per volume): £99 for multi-user institutions, £45 for individual subscribers. Payment may be made in any currency, converted at the current rate. The individual rate is available only to those paying with a personal cheque or credit card.

To subscribe, or to receive a FREE sample copy of the first issue, please use the form below.

SUBSCRIPTION ORDER FORM

Three Junior Faculty Positions

CELLULAR & MOLECULAR PHYSIOLOGY

Applications are solicited for three (3) tenured track positions at the rank of Assistant or Associate Professor (term appointments) in the Department of Cellular and Molecular Physiology, Yale University School of Medicine. Candidates must hold an M.D., Ph.D. or equivalent degree and have experience and interest in Physiology at the cellular and/or molecular levels. We are especially interested in candidates with experience in the areas of neuroscience, membrane biology, and signal transduction. Opportunities are available for both collaborative and independent research as well as for graduate and medical student teaching.

Qualified women and minority group members are encouraged to apply. A complete curriculum vitae, a statement of research interests and goals and three (3) letters of reference should be sent by September 15, 1990 to:

Walter F. Boron, M.D., Ph.D.
Chairman, Department of Cellular and Molecular Physiology

Yale University is an Affirmative Action/Equal Opportunity Employer. (NW5519)A

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a postdoctoral fellowship funded by the Wellcome Trust. The person appointed will study the expression and function of histamine H_1-receptors in cultured cell lines. Research experience in receptor pharmacology, biochemistry or neurochemistry would be an advantage. The appointment is for three years with a starting salary (1A scale) of up to £13,527. This includes an enhancement premium of two incremental points.

MEDICAL SCHOOL TECHNICIAN (MST 1)

Applications are also invited for a research technician post associated with the above project. The work will involve cell culture and analytical techniques and experience in these areas is desirable but not essential. Applicants should have a minimum qualification of HTEC or HNC in an appropriate science subject. The position, which is expected to last three years, is offered for one year in the first instance with a starting salary of £7,897 (under review).

Applications including curriculum vitae (plus contact telephone number) and the names of two academic referees should be sent as soon as possible to **Dr S J Hill, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham, NG7 2UH** from whom further details can be obtained on (0602) 709486. (4145)A

UNIVERSITY OF UTRECHT

The Netherlands

vac.nr. 66048

Professor of Theoretical Biology

Candidates should have proven to be able to conduct a vigorous research program in theoretical biology. The research should aim at providing significant insights, also for experimental biologists, in areas central to biology.
The present research in the department focuses on fundamental theoretical research on processes based on information exchange in biotic systems, ranging from molecular systems to etho-ecological systems. The candidate should be willing to teach biology students (and other students) at undergraduate, graduate and postgraduate level. It is expected that within two years teaching will be in Dutch.

Salary will be in the range Hfl 7.171,– – 10.544,– per month.

Applications, including curriculum vitae, list of publications and the names and addresses of two referees should be sent within weeks following publication of this advertisement to prof. dr. M.J.A. Werger, Dean of the Faculty of Biology, Padualaan 14, 3584 CH Utrecht, the Netherlands (tel. (31)30 532276), from whom further details may be obtained. A profile of the task and the infrastructure is available in Dutch.

Persons who would like to draw the attention of the search committee to possible candidates are warmly invited to write to its chairman.

With equally qualified applicants preference will be given to a woman. (W7520)A

ICARDA

International Centre for Agricultural Research in the Dry Areas

RUMINANT NUTRITIONIST

REF: DG/07/90

Organization: ICARDA, one of 13 international centers supported by the Consultative Group on International Agricultural Research, cooperates with national programs in West Asia and North Africa (WANA) to develop sustainable improvements in dryland cereals, food legumes, farm resources management, pasture, forage, and livestock production. ICARDA's multi-disciplinary staff of over 60 senior scientists and 600 technical and support personnel has an international mandate for barley, faba bean, and lentil production improvement and — with other centers — a joint regional mandate for wheat and chickpea production improvement.

Position: The Ruminant Nutritionist will join a team of scientists conducting research on feed and pasture legumes, native pastures, and livestock systems. Specific responsibilities include:

- Conduct research on the nutritional value of cereal and legume crop residues, in close cooperation with crop improvement scientists;
- Develop feeding strategies involving both traditional and new feed resources that maximize productivity of local and improved small ruminant genotypes;
- Assume full responsibility for a Feed Quality Laboratory;
- Participate in training, both on and off station.

Qualifications: Earned Ph.D. in animal nutrition, or related field; established international reputation or at least 5 years of postdoctoral experience; ability to work collaboratively with scientists of different disciplines and nationalities; demonstrated ability to conduct research, communicate, and publish results.

Post: The position, within the Pasture, Forage and Livestock Program, is based at ICARDA's modern headquarters and main research station located in a rural setting 35 km from Aleppo, Syria; the position involves moderate international travel. Fluency in English, ICARDA's working language, is required. Arabic and/or French capability an advantage.

WATER MANAGEMENT/SUPPLEMENTAL IRRIGATION SPECIALIST

REF: DG/12/90

Organization: ICARDA, one of the 13 international centers supported by the Consultative Group on International Agricultural Research, cooperates with national programs in West Asia and North Africa (WANA) to develop sustainable improvements in dryland cereals, food legumes, farm resources management, pasture, forage, and livestock production. ICARDA's multi-disciplinary staff of over 60 senior scientists and 600 technical and support personnel has an international mandate for barley, faba bean, and lentil production improvement and — with other centers — a joint regional mandate for wheat and chickpea production improvement.

Position: The Water Management/Supplemental Irrigation Specialist is a member of a multi-disciplinary team conducting research in agricultural systems of supplemental irrigation and water harvesting. Responsibilities include:

- Collaborate with national and international scientists to plan, design, implement, manage, and evaluate supplemental irrigation and water harvesting projects aimed at technology transfer in WANA;
- Participate in multi-disciplinary supplemental irrigation and water harvesting research for cereals, pulses, forages, and pasture management;
- Prepare a variety of documents and reports;
- Work with agricultural economists, agronomists, and other team members;
- Assist with organizing and conducting training events.

Qualifications: Earned PhD in agricultural engineering, civil engineering, agronomy or subject involving irrigation; minimum of 2 years relevant research experience; strong background with advanced knowledge and experience in supplemental irrigation and water harvesting; ability to work collaboratively with scientists of different disciplines and nationalities; teaching experience and familiarity with microcomputers and mapping; fluent in spoken and written English; under 60 years of age.

Post: The position reports to the leader, Farm Resources Management Program, and is based at ICARDA's modern headquarters and main research station located in a rural setting 35 km from Aleppo, Syria.

N_2-FIXATION SPECIALIST/SOIL MICROBIOLOGIST

REF: DG/09/90

Organization: ICARDA, one of 13 international centers supported by the Consultative Group on International Agricultural Research, cooperates with national programs in West Asia and North Africa to develop sustainable improvements in dryland cereals, food legumes, farm resources management, pasture, forage and livestock production. ICARDA's multi-disciplinary staff of over 60 senior scientists and 600 technical and support personnel has an international mandate for barley, faba bean, and lentil production improvement and, with other centers, a joint regional mandate for wheat and chickpea production improvement.

Position: The N_2-Fixation Specialist/Soil Microbiologist is part of a multi-disciplinary team seeking to improve sustainability of regional dryland farming systems with specific application to legume biological nitrogen fixation and nitrogen cycling. Main responsibilities include:

- Develop and implement a research program involving role and maximization of fixed nitrogen in crop rotation involving forage and food legumes;
- Strengthen relationships with national programs and assist in developing research capability through training and cooperative projects;
- Produce technical reports and training material;
- Establish effective collaboration with other centers of excellence to augment regional efforts.

Qualifications: Earned PhD in agronomy, soil science, or soil microbiology; at least 5 years research experience in legume N_2 fixation, N cycling, and 15N technique; practical experience in developing countries and/or dryland farming systems desirable. Fluency in written and spoken English is essential.

Post: The position reports to the leader, Food Legume Improvement Program, and is based at ICARDA's modern headquarters and main research station located in a rural setting 35 km from Aleppo, Syria. Arabic and/or French capability would be advantageous.

LEGUME PATHOLOGIST

REF: DG/10/90

Organization: ICARDA, one of the 13 international centers supported by the Consultative Group on International Agricultural Research, cooperates with national programs in West Asia and North Africa to develop sustainable improvements in dryland cereals, food legumes, farm resources management, pasture, forage, and livestock production. ICARDA's multi-disciplinary staff of over 60 senior scientists and 600 technical and support personnel has an international mandate for barley, faba bean, and lentil production improvement and, with other centers, a joint regional mandate for wheat and chickpea production improvement.

Position: The Legume Pathologist works within a multi-disciplinary team seeking ways to stabilize and increase productivity of cool season food and forage legumes through improved host resistance and alternative controls for common diseases, with major emphasis on basic and applied research related to Ascochyta blight, root-rot, rust, and wilt in lentil and chickpea. Main responsibilities include:

- Develop and implement collaborative research programs with breeders on host-plant resistance and appropriate alternative control measures;
- Produce technical reports and training material;
- Strengthen relationships with national programs and assist in developing research capability through training and cooperative projects;
- Establish effective collaboration with other centers of excellence for research on mechanisms of resistance and application of biotechnology to plant disease management.

Qualifications: Earned PhD in plant pathology with at least 5 years research experience in host-plant resistance and alternative control measures. Fluency in written and spoken English is essential. Experience with cool season legumes in developing countries is desirable.

Post: The position reports to the leader, Food Legume Improvement Program, and is based at ICARDA's modern headquarters and main research station located in a rural setting 35 km from Aleppo, Syria. Arabic and/or French capability would be advantageous.

Benefits: Salary paid in US dollars based on experience and qualifications. Benefits include housing allowance, paid home leave travel, a retirement and health package, provided auto, free enrollment for dependents at the ICARDA-administered international school (K-12), and other internationally competitive conditions of service. **Application:** Qualified applicants are invited to send: 1) a curriculum vitae with recent salary history; 2) names, addresses, and telex numbers for three professional referees; 3) photocopies (non-returnable) of other relevant supporting documents, to Dr Aart van Schoonhoven, Deputy Director General/Research ICARDA, PO Box 5466, Aleppo, Syria. Telex: 331208 ICARDA SY, or 331263 ICARDA SY, or 331206 ICARDA SY. Telephone: (963-21) 213433, 213477, or 234890. **Reference:** Please quote position nos on applications. **Application deadline:** Positions open until qualified candidates apply. **Announcement date:** 6 May 1990.

(W7529)A

ICARDA is an Equal Opportunity Employer

WORKSAFE AUSTRALIA
(NATIONAL OCCUPATIONAL HEALTH AND SAFETY COMMISSION)

Australia is introducing a new scheme of chemical notification and assessment to help ensure that hazardous substances are appropriately handled and regulated.

The National Occupational Health and Safety Commission (Worksafe Australia) is a tripartite body which leads national efforts to provide healthy, safe and productive working environments and to reduce the incidence and severity of occupational injury and disease.

The Commission is seeking an experienced executive to direct the Chemicals Notification and Assessment Scheme and administer the day-to-day operation of the Industrial Chemicals (Notification and Assessment) Act 1989. This act establishes a national system of notification and assessment of the potential hazards of industrial chemicals to workers, the community and the general environment.

DIRECTOR
Chemicals Notification and Assessment Scheme
(Senior Executive Band 2)
Sydney

Duties: Under the direction of the Chief Executive Officer, manage the administrative operations and exercise the legislative responsibilities of the Act. Maintain an inventory of chemical substances used in Australia and develop and manage the branch responsible for this work.

Qualifications: Applicants should have highly developed managerial and leadership ability, together with demonstrable knowledge, experience and mature judgement about the use and effects of toxic substances.

The remuneration package for this position totals approximately $A100,000 of which $A69,206 is the salary component.

Australian Public Service conditions of service apply and include four weeks annual leave with bonus payment, cumulative sick leave benefits, long service leave after ten years continuous service and a contributory superannuation scheme. In some circumstances, fares and removal expenses to take up duty and a short term accommodation allowance are payable.

The successful candidate will be offered appointment on a fixed term basis not exceeding five years.

Further information on this position is available from the Chief Executive, Dr Edward Emmett, (02) 265 7500. Duty statement, job description and selection criteria may be obtained from Ms Abi Gough on (02) 265 7454.

Applications addressing the selection criteria and giving full details of experience and qualifications should be forwarded to the:

Personnel Officer (Recruitment)
WORKSAFE AUSTRALIA
GPO Box 58, Sydney, NSW 2001, AUSTRALIA

Applications close: Two weeks from the date of this advertisement.

Worksafe Australia has a policy of a smoke-free working environment, and is an Equal Opportunity Employer (W7550)A

UNIVERSITY OF DUNDEE
DEPARTMENT OF ANATOMY AND PHYSIOLOGY
TEMPORARY LECTURESHIP IN ANATOMY

Applications are invited from experienced medical, dental, or suitably qualified science graduates for a Temporary Lectureship in Anatomy. The appointment will be for one year from 1 October 1990 but an earlier starting date can be arranged.

Salary will be on the Lecturer Grade A scale (£12,086 - £16,755).

Further particulars from, and applications in writing with CV (6 copies or, if posted overseas, one copy in a suitable format for photocopying) and the names and addresses of three referees to, the **Personnel Office, The University, Dundee, DD1 4HN. Please quote reference EST/32/90/N.**

Closing date: 3 August 1990. (4141)A

UNIVERSITY OF GLASGO
Wellcome Laboratories for Experimental Parasitology
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above post to work on the cloning of gen
encoding secreted antigens and proteinases of nematode parasites. The proje
is funded by the Wellcome Trust for three years beginning October 1990. T
successful applicant will join a laboratory working on a variety of projects on
immunochemistry and biochemistry of parasitic nematodes. Experience
molecular biology, biochemistry, or related fields would be advantageou
particularly if in gene cloning.

The post is available from October 1990, but a later date could be negotiated
necessary. Starting salary will be on the University RA 1A scale (stimulated by
increments) from £12,792 to £13,495, depending on age and experience, an
appropriate annual increments thereafter.

Applications including curriculum vitae and the names, addresses and tel
phone numbers of at least two adademic referees should be sent as soon a
possible to **Dr Malcolm Kennedy, Wellcome Laboratories for Experiment
Parasitology, University of Glasgow, Bearsden, Glasgow G61 1HQ** to who
informal enquiries can be made on 041-339 8855 Extn 5819 or 6968. (4138)A

The Queen's University of Belfast
RESEARCH FELLOW
Department of Agricultural Botany

The above post, located at the Plant Testing Station, Crossnacreevy
Belfast, is available initially for one year from 1 September 1990 fo
work on cereal variety evaluation based on field experiments con
ducted at various sites throughout Northern Ireland. Data on yield
quality and agronomic characteristics are collected, processed an
interpreted to provide information on varieties suitable for produc
tion in Northern Ireland. Duties will include management of the fiel
trials, data collection and processing and the formulation of report
on varieties. The appointee will be involved in communicatin
information to various sectors of the agricultural industry in Norther
Ireland.

Applicants must hold a Degree in Agricultural Botany or a relate
subject and a PhD or have five years postgraduate research experience. Experience of staff management and computing is essential.

Salary scale: £10,458-£12,381 per annum (under review), placing depending on age, qualifications and experience.

Applicants, quoting ref. 90/HH, should submit a curriculum vitae, including the names and addresses of two referees to the **Personnel Officer, The Queen's University of Belfast, Northern Ireland, BT7 1NN.** Closing date: 27 July 1990.

The University is an Equal Opportunity employer. The University may decide to interview only those applicants who appear, from the information available, to be the most suitable, in terms of experience, qualifications and other requirements of the post. (4128)A

THE CHARING CROSS SUNLEY RESEARCH CENTRE
IMMUNOLOGY UNIT
POSTDOCTORAL FELLOWS

Two Vacancies:

1) **Molecular Biologist** to work in a group studying the structure and function of the receptors for tumour necrosis factor and their role in disease processes. Experience in cDNA cloning, mammalian cell expression and PCR an advantage.

2) **Cell Biologist** to work in a group studying cytokine production and regulation of endothelium by cytokines. Experience in endothelial cell culture and/or coagulation is desirable.

For further details contact Prof. M. Feldmann (project 1 or 2), Dr. C. Haworth (2) or Dr. F. Brennan (1).

Salaries in the range £12,225-£18,432 (Research Scale 1A) depending on age and experience.

Closing date: (4 weeks after publication date).

Applications, including a full C.V. and the names and addresses of two referees should be sent to:

Mrs. J. Brewer
The Charing Cross Sunley Research Centre
1 Lurgan Avenue, Hammersmith
London W6 8LW
(Tel: 081-741 8966)

(4129)A

Cancer Research Campaign

- We are the biggest funder of cancer research scientists, supporting some 700 projects in universities, medical schools and research institutes throughout Britain
- We have developed a strong interface between research and clinical therapy, facilitating the effective development and implementation of cancer treatments
- Of the nearly £40 million we raised through voluntary contributions in1989, 92% went directly into research - accounting for around 40% of all cancer research in the UK.

INSTITUTE OF CANCER RESEARCH, (University of London)

POST-DOCTORAL SCIENTIST, Sutton, Surrey

Applications are invited for a postdoctoral research fellow to join a multidisciplinary team working within the new Molecular Carcinogenesis Section. Major interests of the team include (i) the isolation of new oncogenes that are involved in the development of human soft tissue tumours and (ii) the characterisation of a novel growth receptor encoded by the MET protooncogene and the identification of the growth factor that binds to this receptor. The person appointed will be expected to take scientific responsibility for work on the MET growth factor receptor but depending upon background and interests will have the opportunity to become involved in other research projects. Prior experience in molecular biological techniques, although by no means essential, would be an advantage. The post is for three years in the first instance. Salary will be in the range £12,108 to £17,022 inclusive, according to experience.

Applications should be sent in duplicate, with the names and addresses of two referees to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting reference number 7.90.S.N.17.

THE BEATSON INSTITUTE FOR CANCER RESEARCH

RESEARCH SCIENTIST, Glasgow

There is a vacancy for a scientist in a group studying the mechanisms regulating changes in gene expression and leukaemogenesis in human myeloid cells. Candidates should have experience of cell and molecular biology techniques, an interest in the regulation of gene expression in eukaryotes, and a willingness to explore new directions. The appointment will be within a salary range of £12,086 to £22,311 per annum at a point appropriate to age and relevant experience, and will be for three to five years, with possibility of extension depending on the incumbent's progress and proven ability.

Applications, with CV and names and addresses of three referees, should be sent to Dr G D Birnie, The Beatson Institute for Cancer Research, Garscube Estate, Switchback Road, Bearsden, Glasgow G61 1BD, from whom further details can be obtained.

CRC HUMAN CANCER GENETICS RESEARCH GROUP,

University of Cambridge

We are a major CRC-funded group working at the interface between the clinical and molecular genetics of cancers in man. We are based in new laboratories in the University Department of Pathology in the centre of Cambridge.

RESEARCH TECHNICIAN

The successful applicant will work closely with a team leader on a project to map genes involved in the development of human cancers, in addition to a share of laboratory duties in support of the team as a whole.

Experience and proven ability to get results with basic molecular genetic techniques are required. This post is suitable for someone who enjoys getting techniques to work; and further training will be given. It is not suitable for someone wishing to do a Ph.D. while in post.

Appointment for 3 years in the first instance. Salary according to age and experience in range £9,672 to £11,898 (under review).

RESEARCH ASSISTANT

The successful applicant will be responsible for developing the molecular genetic aspects of our studies of human ovarian and breast cancer, including the development of new highly polymorphic probes based on PCR techniques. Training and supervision will be available if required.

Applicants may or may not have a Ph.D. Experience and demonstrated success with basic molecular genetic techniques (blotting, genomic cloning) is essential.

Appointment for 3 years in the first instance. Salary according to age and experience in range £11,399 to £16,755.

Applications for both the above positions should be made to Dr Bruce Ponder, CRC Human Cancer Genetics Research Group, Department of Pathology, University of Cambridge, Tennis Court Road, Cambridge CB2 1QP.

Applicants are advised that smoking is prohibited in the majority of our premises.

Fighting cancer on all fronts. (4154)A

KING'S COLLEGE SCHOOL OF MEDICINE AND DENTISTRY of King's College London

Department of Immunology

RESEARCH ASSISTANT IN DIABETIC RESEARCH

Applications are invited for a 2 year post to undertake a study of the immunopathogenesis of diabetes in the non-obese diabetic mouse. The post is based in the Department of Immunology where the successful candidate will join a group dedicated to elucidating the role of T lymphocytes and their soluble products in the immunopathogenesis of insulin dependent diabetes. The post would suit a young graduate with an enquiring mind for whom a career in research is the prime motivation. King's has excellent post-graduate facilities and the salary will be according to the Research Assistant's scale. For further details and informal discussions please contact Dr D Vergani or Dr M Peakman (telephone 071 326 3588). Application in the form of a CV naming two referees should be sent to the **Secretary of the Medical School, Bessemer Road, London SE5 9PJ**, by 28 July 1990. (4151)A

POSTDOCTORAL POSITION

Jointly administered by Department of Environmental Engineering, California Institute of Technology and Department of Experimental Cardiology, Huntington Medical Research Institutes, Pasadena, CA. Purpose to identify nitric oxide or its various precursor materials in biological systems (from endothelial cells). The findings will be correlated with the biopharmacological effect of these nitrogenous substances using bioassays systems. Experience in chemistry and interest in biomedical problems desirable. Starting date Summer or early Fall. Send applications to **Richard J. Bing, M.D., Huntington Medical Research Institutes, 734 Fairmount Avenue, Pasadena, CA 91105.** (818) 397-5451. *EOE/AA.* (NW5524)A

THE INTERNATIONAL ATOMIC ENERGY AGENCY

SEEKS

Head, of Soil Fertility, Irrigation and Crop Production Section for the Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, Vienna, Austria.

Applicants should hold a Ph.D. degree in soil science, plant nutrition, root biology, soil microbiology or a related subject and have 15 years of research experience including work with isotopes, radiation and biotechnological techniques in one or more of the above topics. Relevant experience in developing countries would be an asset. Experience with international programmes and adminstration desirable.

The Head of the Soil Fertility, Irrigation and Crop Production assists in formulating and guiding the Joint FAO/IAEA programme to assist Member States to apply nuclear and related techniques in research relevant to maximising efficiency in the use of soil resources and applied fertilizer and water using agronomic and plant genotypic approaches, to enhancing soil fertility via management of biological nitogen fixation of grain legume and trees, and to soil conservation.

Tax free emoluments of approximately $US65,600 p.a. Initial contract for three years. Additional allowances for dependants. Six weeks annual leave. Travel and removal expenses paid. Applicants should send their curriculum vitae quoting Vacancy Notice No. 90/028 to the **Division of Personnel, International Atomic Energy Agency, P.O. Box 100, Wagramerstrasse 5, A-1400 Vienna, Austria, before August 24th 1990.** (W7542)A

University of Sheffield

DEPARTMENT OF MEDICINE & PHARMACOLOGY

TWO NON-CLINICAL LECTURESHIPS IN MOLECULAR MEDICINE

Applications are invited from candidates with good records of academic achievement for two Non-Clinical Lectureships:

For one post, candidates must have a sound understanding and experience of advanced molecular biology techniques and DNA analysis, particularly in relation to the use of the polymerase chain reaction DNA amplification procedure. Ref. MAP 302A/G.

Candidates for the other post should have a background in one of the following: DNA cloning and sequencing; gene regulation studies; protein biochemistry; cytokine/growth factor cell biology; molecular virology; biochemical immunology. Applicants must be capable of developing and leading a competitive research group within one of the above areas. **Ref. 302B/G.**

Salaries on Grade A (£10,458-£15,372 pa, under review) or Grade B (£16,014-£20,469 pa, under review).

Further details from Director of Personnel Services, The University, Sheffield, S10 2TN, to whom applications including a full CV and the names/addresses of three referees (six copies of all documents), should be returned by **15 August 1990.** Please quote appropriate reference.

An Equal Opportunity Employer

(4142)A

at the leading edge

CHAIR, DEPARTMENT OF ENTOMOLOGY & APPLIED ECOLOGY

Applications are invited for Professor and Chair, Department of Entomology and Applied Ecology, University of Delaware. We seek candidates who will continue superior achievement in research and who demonstrate commitment to quality undergraduate and graduate instruction. Research speciality is open. Persons using insect models in disciplines other than entomology are encouraged to apply.

Salary and fringe benefits are competitive. Committed to academic excellence, the University of Delaware is a mid-sized comprehensive land grant institution with convenient access to major museum, USDA and industrial research facilities. The position is available July 1, 1991; final application deadline is September 15, 1990. The search will continue until the position is filled.

Send full curriculum vitae, including complete funding and publication record, and names, addresses, and telephone numbers of four references to: **Dr. John Dohns, Search Committee Chair, Entomology and Applied Ecology, University of Delaware, Newark, DE 19717-1303.**

The UNIVERSITY OF DELAWARE is an Equal Opportunity Employer which encourages applications from Minority Group Members and Women.

(NW5514)A

UNIVERSITY OF WARWICK

Nonlinear Systems Laboratory

EXPERIMENTAL RESEARCH FELLOW TO STUDY CHAOS

A SERC-sponsored postdoctoral position to conduct experimental investigations with Dr C P King of chaotic advection in a simple fluid.

Experimental experience is required. Experience in fluid mechanisms or chaotic dynamical systems desirable but not essential.

The appointment is for two years and is available from 1 October 1990. Salary will be up to £13527 on the Research Range IA scale: £10458 – £16665 pa (under review) depending on age and experience.

Send curriculum vitae, description of interests and names and addresses of two referees to **Dr G P King, Nonlinear Systems Laboratory, Mathematics Institute, University of Warwick, Coventry CV4 7AL. Closing date 27 July 1990.**

AN EQUAL OPPORTUNITIES EMPLOYER. (4121)A

UNIVERSITY OF MANCHESTER

SCHOOL OF BIOLOGICAL SCIENCES

DEPARTMENT OF CELL AND STRUCTURAL BIOLOGY

CHAIR IN DEVELOPMENTAL BIOLOGY

The purpose of this new initiative is to complement existing strengths to make Manchester an internationally renowned centre of excellence in Developmental Biology. The principle criteria of appointment therefore, will be research excellence and/or research potential. Applications are invited from workers in all fields of developmental research: invertebrates, vertebrates, molecular, cellular or organismic aspects. The department already has major research projects in vertebrate: transcription factors and pattern formation, sex determination, implantation, gastrulation, craniofacial development, wound healing, growth factors, is well equipped for molecular, cellular and whole animal investigations, has a lively research atmosphere and excellent local and international collaborations. The person appointed will be responsible for teaching courses (with others) in Developmental Biology to medical, dental and science students, in which there is considerable scope for innovation. Opportunities exist to develop new teaching and research interests within the wide range of activities encompassed by the School of Biological Sciences. Informal enquiries to **Professor Mark W. J. Ferguson, Head of Department of Cell and Structural Biology (Tel: 061 275 6775).** Further particulars from the **Registrar, the University, Manchester M13 9PL** to whom applications (full curriculum vitae, names and addresses of three referees, and an outline research programme) should be sent by September 30th, 1990. *The University is an Equal Opportunity Employer.* (4125)A

Multidimensional Magnetic Resonance

Memorial Sloan-Kettering Cancer Center

Sloan-Kettering Institute, Memorial Sloan-Kettering Cancer Center is seeking an individual at the Assistant Member level to establish an independent program in multidimensional magnetic resonance studies of biologically active molecules. While the research activity will be independent, it is expected that the successful candidate will interact with other investigators at the Institute who are concerned with protein, nucelic acid and oligosaccharide structure and conformation. In support of these goals, the institute will make a significant investment in state-of-the-art magnetic resonance facilities and associated computational resources.

Applicants should provide a curriculum vitae and bibliography, three or more letters of recommendation from knowledgeable senior scientists in the field, and a thorough statement of research goals with some representative specific proposals.

All materials should be sent to:

Richard A. Rifkind, M.D.
Chairman, Sloan-Kettering Institute
Memorial Sloan-Kettering Cancer Centre
1275 York Avenue
New York, New York 10021

An Equal Opportunity/Affirmative Action Employer

(NW5525)A

THE AUSTRALIAN NATIONAL UNIVERSITY — The John Curtin School of Medical Research

DIVISION OF BIOCHEMISTRY AND MOLECULAR BIOLOGY

Research Fellow/Senior Research Fellow
Medical Molecular Biology

A position of research fellow/senior research fellow is available in the Medical Molecular Biology Group to collaborate with Professor Ian Young on the molecular biology of haemopoietic growth factors. Current research interests of the group include expression and structure-function studies on interleukin-5, molecular organisation and regulation of the interleukin-3 and interleukin-5 genes and gene targeting by homologous recombination.

Enquiries to Professor Young 61 6 249 0176 Ref JC 26.6.1

Postdoctoral Fellow/Research Fellow
Membrane Biochemistry

A position of postdoctoral fellow/research fellow is available in the Membrane Biochemistry Group to collaborate with Dr G. Cox in work on structure-function relationships in a number of membrane-associated complexes. Work is currently concentrated on the ATP synthase of *E. coli*; the two phosphate transport systems of *E. coli* and the human GABA-receptor. The experimental approaches used include gene cloning, DNA sequencing, mutagenesis, protein purification, in vitro membrane reconstitution and molecular model building. Structural studies are carried out in collaboration with NMR spectroscopists and X-ray crystallographers and functional studies with members of the Division of Neurosciences, JCSMR.

Enquiries to Dr Cox 61 6 249 2759 Ref JC 26.6.2

Postdoctoral Fellow/Research Fellow
Protein Biochemistry

Applications are sought from scientists with a PhD in biochemistry to work in collaboration with Dr Michael Denborough on the molecular basis of the anaesthetic complication, malignant hyperpyrexia. Experience in biochemistry, molecular biology and pharmacology is essential, and experience in phosphoinositide biochemistry would be a considerable advantage.

Enquiries to Dr Denborough 61 6 249 2207 Ref JC 26.6.3

Postdoctoral Fellow/Research Fellow
(Signal Transduction/Receptors) – Protein Biochemistry

Applications are invited from scientists with research interests within the general area of cell surface receptors and signal transduction in mammalian cells. The successful applicant would join a newly established Receptor-Cell signalling laboratory (Head: Dr P. D. Jeffrey) and would be given the opportunity to develop an independent research project on some aspect of biological signal transduction at the molecular level. Collaboration within the new laboratory or with other members of the Division would also be encouraged. Relevant aspects of research in the Division include protein-receptor interactions, signalling from growth factor receptors and ion channels and regulation of gene expression via signalling events.

Enquiries to Dr Jeffrey 61 6 249 3652 Ref JC 26.6.4

DIVISION OF CELL BIOLOGY

Postdoctoral Fellow/Research Fellow
(Immunologist/Cell Biologist) – Cell–Cell Interaction

Applications are invited from PhD graduates in immunology/cell biology for a position in the Cell–Cell Interaction Group to carry out research in collaboration with Dr C. R. Parish, leader of the group. The appointee will be involved in the identification and characterisation of cell adhesion molecules involved in lymphocyte recirculation and leukocyte-endothelial cell interactions. Familiarity with the biochemical analysis of cell membranes, cell culture techniques and the use of monoclonal antibodies is desirable.

Enquiries: Dr Parish 61 6 249 2604 Ref JC 26.6.5

Postdoctoral Fellow/Research Fellow
(Virologist/Immunologist) – Viral Engineering

Applications are invited from PhD graduates in Virology or Immunology for a position in the Viral Immunology Group to carry out research in collaboration with Professor R. V. Blanden, Group Leader and Dr A. Müllbacher. The appointee will be involved in the production of recombinant vaccinia, adeno, and alpha viruses encoding flavivirus proteins. The recombinants will be used to define areas of flavivirus proteins relevant to T lymphocyte epitopes, their relationship to B lymphocyte epitopes and their potential relevance in vaccines. Experience with the molecular virology of flaviviruses is highly desirable.

Enquiries: Professor Blanden 61 6 249 2596 Ref JC 26.6.6

Postdoctoral Fellow – Cell Transformation

A postdoctoral fellow is required to work in the Cell Transformation Group in collaboration with Dr A. W. Braithwaite. Work of the group concerns the roles of cellular and viral oncogenes (mainly Ela, T ag and P53) in control of gene expression, DNA replication, the cell growth cycle and differentiation. Preference will be given to candidates with experience in the molecular and cellular biology of cancer and cell transformation.

Enquiries: Dr Braithwaite 61 6 249 4480 Ref JC 26.6.7

DIVISION OF CLINICAL SCIENCES

Postdoctoral Fellow/Research Fellow —
Mucosal Inflammation and Cancer

A PhD graduate with expertise in free oxy-radicals is sought to collaborate with Professor Doe and Dr Baker in the Mucosal Inflammation and Cancer research program that focuses on the molecular basis of tissue injury in inflammation, especially oxy-radicals, serine proteases and cytokines. The research project will examine the role of inflammatory cell oxy-radicals and their products in the mediation of tissue injury in chronic mucosal inflammation, using an epithelial cell model and tissue from patients suffering from inflammatory bowel disease. Contemporary techniques will be used to study free radicals and to analyse intra and extracellular targets of free radical damage.

Enquiries: Professor Doe 61 6 249 2392 Ref JC 26.6.8

Postdoctoral Fellow — Developmental Haematology

A molecular cell biologist with an interest in cell differentiation is sought, to collaborate with Dr A. J. Hapel and Dr M. C. Fung in the Developmental Haematology Group on research in the area of signal transduction and/or gene regulation by haemopoietic cytokines. There is particular interest in discriminating at a molecular level signals essential for proliferation from those required to induce phenotypic changes (maturation) of bone marrow cells.

Enquiries: Dr Hapel 61 6 249 2381 Ref JC 26.6.9

DIVISION OF NEUROSCIENCE

Postdoctoral Fellow — Developmental Neurobiology

A postdoctoral fellow is required in the Developmental Neurobiology Group to collaborate with Dr C. Hill. The research will involve the biology of the developing autonomic nervous system, in particular the factors influencing the direction of axon outgrowth and the formulation of synapses and modulation of transmitter release. Such a person should have some experience in either *in vivo* or *in vitro* techniques pertinent to this area as well as some knowledge of biochemical or molecular biological methodology.

Enquiries: Dr Hill 61 6 249 4780 Ref JC 26.6.10

Postdoctoral Fellow/Research Fellow —
Neurophysiology OR Visual Neuroscience

An appointment is available, to be made either in the Neurophysiology Group or in the Visual Neuroscience Group,

— either to collaborate with Professor Redman in research on junctional mechanisms at central synapses, particularly in the hippocampus and spinal cord. Experience with *in vitro* slice preparation and whole cell recording techniques would be an advantage;

— or, to collaborate with Professor Levick in research on the spatial structure of pharmacological and electrical sensitivity in the dendritic fields of retinal ganglion cells *in vitro*. Previous experience in appropriate recording and micro-pharmacological techniques is desirable.

Enquiries: Professor, Redman, Neurophysiology 61 6 249 2602
Professor Levick, Visual Neuroscience 61 6 249 2525

Closing date: 10 August 1990 Ref JC 26.6.11

DIVISION OF CLINICAL SCIENCES

Mucosal Inflammation and Cancer Group

Postdoctoral Fellow/Research Fellow
(Molecular Geneticist/Molecular Biologist)

A PhD graduate molecular geneticist or biologist is sought to work on colon cancer genetics, especially familial non-polyposis colon cancer. The group comprises two cell biologists, a protein chemist and a molecular biologist, graduate students and technical support, and has a long-standing interest in colon epithelial cell transformation invasion and metastasis at the molecular level, and in colon cancer genetics.

Established experience in molecular genetics, preferably including random gene probing and candidate chromosome analysis is desirable. The successful applicant will work in a newly refurbished laboratory well equipped for molecular biology and molecular genetics, have ready access to a "state of the art" facility for oligonucleotide synthesis and automated DNA sequencing, and technical support. The project is funded by an external grant.

Enquiries: to Professor Doe — 61 6 249 2392.

Conditions

PDF: Appointment will be for 2 years initially, with the possibility of extension to a maximum of three years.

RF: Appointment will be for three years initially. If external funding permits, there is the possibility of extension, after review, to a maximum term of five years.

Closing date: 3 August 1990. Ref JC 26.6.12

Details of these positions may be obtained from the School Secretary JCSMR (Telephone 61 6-2492580) or by writing to the Registrar.

SALARY: Senior Research Fellow: A$45,729-A$54,255 p.a.; Research Fellow: A$33,163-A$43,096 p.a.; Postdoctoral Fellow Grade 1 (fixed point): A$28,792-A$32,762 p.a.

APPOINTMENT: Unless otherwise stated, Senior Research Fellow/Research Fellow up to three years, possibility of extension to five years; Postdoctoral Fellow up to two years, possibility of extension to three years.

APPLICATIONS should be submitted in duplicate to the **Registrar, the Australian National University, GPO Box 4, Canberra ACT 2601, Australia,** quoting reference number and including curriculum vitae, list of publications and names of at least three referees. The University reserves the right no to make an appointment or to appoint by invitation at any time. Further information is available from the Registrar, or from Appointments (38137), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER (W7553)A

IMMUNO

AKTIENGESELLSCHAFT FÜR
CHEMISCH-MEDIZINISCHE PRODUKTE

Leading international manufacturer of biologics noted for pharmaceutical industrial research, due to further expansion, has immediate opening for

BIOCHEMIST

Candidates should have a Ph.D. in biochemistry, basic protein chemistry skills and relevant experience with isolaton, purification and characterization of proteins, protein sequencing, peptide mapping and amino acid analysis. Knowledge of plasminogen activators and clotting factors is preferred. Experience in carbohydrate-structure determination is a plus. Further, the scope of activities will include directing technicians in the development of assays, working with such techniques as HPLC, FPLC and conventional chromatographic techniques.

The position is a challenging opportunity for candidates looking for a responsible job with ample scope for development. Attractive salary plus benefits package is available. Compensation for re-location expenses will be provided.

Please send detailed résumé (including handwritten CV, remuneration required, date of availability) to REF 94/90

PLANT/PATHOGEN MOLECULAR BIOLOGIST

The Department of Plant Pathology, University of California, Davis, invites applications for an 11-month (1 month vacation) tenure-track position, at the assistant professor level. The starting date is January 1, 1991, or as soon thereafter as the successful candidate is available.

The successful applicant will be expected to develop a research program dealing with the mechanisms which regulate the interaction between plants and pathogens at the molecular level. The focus can be on either the plant or the pathogen and can include molecular biology, cell biology, biochemistry, biophysics, genetics.

Participation in teaching of graduate and undergraduate courses and participation in seminar courses related to the applicant's expertise will be required. The applicant will be expected to supervise graduate students in plant pathology and related graduate groups, and may advise undergraduate students.

Applicants should have a Ph.D. in a discipline related to the study of molecular mechanisms regulating plant disease. Postdoctoral experience is highly desired but not required. Applicants should submit: (a) curriculum vitae, (b) list of published work and reprints, (c) a statement of teaching and research interests, (d) names and addresses of three references, and (e) undergraduate and graduate transcripts, if Ph.D. degree completed within the last five years, to:

Dr. David G. Gilchrist, Chairman, Search Committee
Department of Plant Pathology
University of California, Davis, CA 95616
Telephone: (916) 752-6938/0300

Application deadline: October 1, 1990.

THE UNIVERSITY OF CALIFORNIA IS AN AFFIRMATIVE ACTION/ EQUAL OPPORTUNITY EMPLOYER. (NW5522)A

UNIVERSITY OF QUEENSLAND

Brisbane, Australia

DEPARTMENT OF BOTANY

The Department is the leading provider in Queensland, and one of the leading providers in Australia, of undergraduate and postgraduate education in plant biology. Its goal is to address regionally and nationally important issues, in particular the conservation, management and, where appropriate, rehabilitation of valuable ecosystems through an understanding of process in plants and the dynamics of vegetation and evolutionary change. To this end, it will appoint two new staff, the Chair of Botany and a Lecturer (tenurable) in Marine Botany. It is planned to relocate the Department in 1993 into a refurbished building within the biology precinct.

CHAIR OF BOTANY

The appointee will be a distinguished experimentalist in the areas of ecology and evolution of tropical terrestrial plants and plant communities, who will provide academic leadership to the Department as a whole, and enhance the strengths of the different areas of teaching and research activity.

A particular responsibility will be to provide leadership to the ecology and physiology group, which currently includes 5 academic staff, and is concerned primarily with the understanding of processes within tropical and subtropical forests as a basis for their conservation and management. A major research project of the group is located in a southern Queensland rainforest, and joint research programmes link the Department with several state and federal agencies, with the Institute of Rainforest Studies in Cairns, and with overseas researchers. The position also allows exciting opportunities for the development of collaborative research programmes within the University under the auspices of a Centre for Conservation Biology which will provide a focus for the research of whole-organism biologists.

The appointee will be expected to assume the Headship of the Department for a period of 5 years in the first instance.

Salary: A$67,812 per annum. (A salary loading for Headship applies).

Reference No: 33590 Closing date: **30 August 1990**

LECTURER IN BOTANY
(Tenurable)

The successful applicant will have an established record and an active research interest in marine botany, preferably in subtropical or tropical areas. The appointee will be expected to teach in botany, with particular responsibility for undergraduate subjects and postgraduate supervision in marine botany, to conduct research in marine botany, and to contribute to the scholarly activities of the Department. Outstanding opportunities exist for collaborative teaching in the School of Marine Science within the University, and for research at Heron Island on the Great Barrier Reef, in coastal southern Queensland, and in experimental marine and freshwater aquaculture facilities in Brisbane and nearby.

Salary: A$33,163 – A$43,096 per annum.

Reference No: 33690 Closing date: **30 August 1990**

Application forms and further details concerning method of application are available from Appointments (38145), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

Equal Opportunity in Employment is University Policy (W7532)A

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOLOGICAL SCIENCES

LECTURESHIP IN GENETICS

Applications are invited from outstanding candidates in the field of molecular genetics for a lectureship which is available from 1 October 1990.

Candidates with research experience and interests in the molecular genetics of eukaryotes are especially encouraged to apply, although applications in prokaryotic genetics will also be welcomed.

The salary is negotiable and will be within the Non-clinical Lecturer scale (Grade A: £12,086-£16,755; Grade B: £17,455-£22,311). The appointee will be encouraged to rapidly establish a research programme in an active and well-equipped department and to teach at junior and senior levels in BSc Hons courses in biological sciences.

Further information can be obtained by telephoning 0382 23181 ext. 4767.

Applications in writing with curriculum vitae (6 copies or, if posted overseas, one copy in a format suitable for photocopying) and the names and addresses of three referees should be sent as soon as possible to the **Personnel Office, The University, Dundee, DD1 4HN.** *Please quote reference EST/33/90/N.* (4159)A

National Institute for Biological Standards and Control

Head of Division of Haematology

Applications are invited for the position of Head of the Division of Haematology at NIBSC which will become vacant in October 1990 upon the retirement of the present post-holder, Dr. D. P. Thomas.

The division takes a leading role both nationally and internationally in the standardization and control of therapeutic products used in the field of haemostasis and thrombosis; these functions are supported by an active research programme. Current work is focused on clotting factor concentrates, anticoagulants and thrombolytic drugs and increasingly involves evaluation of products derived by recombinant DNA methods. The Institute liaises with the UK Blood Transfusion Service and plans to strengthen its activities in the field of transfusion medicine, including work on immunohaematology. It is anticipated that this development will be further strengthened and co-ordinated by the new Head of Division.

The Division provides advice to the Medicines Control Agency and the Committee on Safety of Medicines. It collaborates closely with the World Health Organization in the establishment of International Standards in the field of blood products and is increasingly active in the European Community. The Institute operates a multi-disciplinary grouping of collaborating scientific divisions, which are supported by a range of service and administrative units.

Candidates should have medical and/or scientific qualifications with previous experience in haematology and/or transfusion medicine as well as an excellent track record in an appropriate field of scientific research.

Salary will be on an appropriate scale up to £34,203 per annum (under review); however, salary may be negotiable beyond this point for exceptionally well qualified and experienced candidates.

Informal enquiries may be made to the Director, Dr. G. C. Schild.

Further details are available from the Personnel Department.

Applications, with full curriculum vitae, should be made to the Director, NIBSC, Blanche Lane, South Mimms, Potters Bar, Hertfordshire EN6 3QG. Tel: 0707 54753.
Please quote reference number: BL/032.

Closing date for applications is: 3rd August 1990. (4120)A

University of Cambridge
Department of Clinical Biochemistry

Research Assistant/Associate

A position is available for 2 years initially from September 1990 on a project involving the isolation and molecular cloning of pancreatic islet proteins which are targets of cell-mediated autoimmune attack in diabetes (see Roep et al., (1990), Nature 345: 632). The applicant should have academic qualifications in either immunology, biochemistry or molecular biology. Experience with protein purification, recombinant DNA techniques and mammalian tissue culture would be a considerable advantage.

The appointment will be on the Cambridge unestablished research workers salary scale up of £14,744 p.a. depending upon age and experience. Applications with a full curriculum vitae and the names of at least two referees should be sent to **Dr. J. C. Hutton, Department of Clinical Biochemistry, University of Cambridge, Addenbrooke's Hospital, Hills Road, Cambridge, CB2 2QR, U.K.** from whom further details can be obtained. Tel. (0223) 336790, Fax. (0223) 216862.

The University follows an equal opportunities policy. (4133)A

UNIVERSITÄT ULM

In der Abteilung Vergleichende Neurobiologie der Universität Ulm ist eine

Postdoktorandenstelle (BAT IIa) Neuro-/Zellbiologie

für 2 Jahre im Projekt über Hormonregulation im Gehirn und Thymus zu besetzen.

Voraussetzung: Erfahrung mit Immuncytochemie und/oder in-situ-Hybridisierung.

Schwerbehinderte werden bei entsprechender Eignung vorrangig eingestellt.

Bewerbungen an: Prof. Dr. G. Ehret, Abteilung Vergleichende Neurobiologie, Universität Ulm, Postfach 40 66, D-7900 Ulm. (W7535)A

EXECUTIVE DIRECTOR

The Center for Field Research-Earthwatch is seeking a senior scientist to administer our grants program in support of field research in the physical, biological, and social sciences. The 1991 program will provide over $3 million for 135 projects in 60 countries and 20 states. The Executive Director's responsibilities include overall program analysis, advising program officers, representing CFR-Earthwatch at major conferences, development of education and scholarship programs, and procurement of external research support. Excellent organizational and personnel skills are required to work with other managers in field operations, publications, development, and finance. Applications should be received by 1 August 1990. Send CV and three references to **Dr. R. D. Estes, Acting Director, Center for Field Research, Earthwatch, P.O. Box 403, Watertown, MA 02172.** (NW5521)A

Royal Postgraduate Medical School
(University of London)

(Hammersmith Hospital)
DEPARTMENT OF VIROLOGY

Lecturer or Senior Lecturer

Applications are invited for a permanent (tenure-track) position in the Department of Virology. Appointment will be made either at Lecturer or Senior Lecturer level depending upon the qualifications and expertise of the applicant. Medically qualified persons may be appointed to an Honorary Consultant post in the Hammersmith Hospital. The ideal candidate will have a strong interest in basic research, some experience in molecular and cellular biology, and the desire to establish an independent scientific research programme in an area of medical-related virology. There is a teaching commitment in the Department and some experience in lecturing and training PhD students will be an advantage. The current interest in the Department centres around herpes — and oncogenic viruses, but applicants from other areas of virology are also welcomed. The Department is modern and well-equipped, and expansion is planned within 6-9 months to include a central service in molecular biology and tissue culture. Appointment may be made subject to a review or probationary period and salary will be appropriate to the qualifications and experience of the appointee.

Informal enquiries to Professor Beverly Griffin, Department of Virology, telephone 081-740 3248.

Letters of application, together with a full c.v. (7 copies) plus the name and addresses of 3 referees should be sent to the **Personnel Officer, Royal Postgraduate Medical School, Ducane Road, London W12 0NN (tel: 081 740 3204)** from whom further particulars are available. Ref: AV02

Closing date: 31 August 1990.

Laboratory Manager/MLSO 3/4

The Department of Virology at the RPMS has grown over the last few years to the point where it becomes desirable to establish a new position of **Laboratory Manager**. It is hoped to appoint at a senior level someone with a strong interest in laboratory science and management skills. There is considerable flexibility in the post, but preference will be given to a person with an interest and experience in microbiology, seeking a career that involves decision taking and responsibility. The department has an active interest in both clinical diagnosis and research into viruses associated with human disease, especially oncology. For details, contact the **Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road, London W12 0NN or telephone 081-740 3204.** Salary scale, up to £17304 (+ £1580 London Allowance) MLSO 3 or exceptionally MLSO 4, depending upon qualifications and experience. The holder of this post will be directly responsible to the Head of the Department.

Closing Date: 31 July 1990.

(4134)A

MOREDUN RESEARCH INSTITUTE

Higher and Senior Scientific Officer (2 posts)

(Three-year Appointments)

Applications are invited for the following 2 posts at Senior Scientific Officer (SSO) or Higher Scientific Officer (HSO) grades.

Post 1 (readvertised). Ref: MRI 1.

A protein biochemist or chemist, preferably with experience of isolating and characterising proteins from membranes and other subcellular fractions, is required to join a multidisciplinary team investigating the immunogenicity of proteins/peptides derived from the protozoan parasite *Toxoplasma gondii.*

Post 2. Ref: ADRA 1.

A biochemist/immunologist with experience in protein chemistry to join a group studying the role of serine proteases and their inhibitors (serpins) in the pathogenesis of disease. The successful applicant would study the role of neutrophil serine proteases and of serpins in the pathogenesis of equine endometritis (Funded by the Horse Race Betting Levy Board).

Applicants must have a 1st or upper 2nd honours degree in biological sciences or equivalent qualification. A PhD or postgraduate experience relevant to the respective duties will be advantageous.

Salary scales:- HSO £10,678-14,909 SSO £13,254-18,864.

Applications, in triplicate, with full CV and the names and addresses of two referees, should be sent to the **Secretary, Moredun Research Institute, 408 Gilmerton Road, Edinburgh EH17 7JH.**

Informal enquiries to Tel: (031) 664 3262 (Dr. H.R.P. Miller or Dr. D. Baird). Fax: (031) 664 8001. (4157)A

UNIVERSITY OF GLASGOW
Wellcome Laboratories for Experimental Parasitology
RESEARCH ASSISTANT

Applications are invited for the above post to work on the secreted antigens an proteinases of nematode parasites. The project is funded by the Wellcome Trus for three years beginning October 1990. The successful applicant will join laboratory working on a variety of projects on the immunochemistry a biochemistry of parasitic nematodes. Applicants should have a good honour degree in molecular biology, biochemistry, or related fields.

The post is available from October 1990, and carries with it the opportunity fo registration for a higher degree. Starting salary will be on the University RA 1 scale (stimulated by 2 increments) from £12,792 and appropriate annual increments thereafter.

Applications including curriculum vitae and the names, addresses and telephone numbers of at least two adademic referees should be sent as soon as possible to **Dr Malcolm Kennedy, Wellcome Laboratories for Experimental Parasitology, University of Glasgow, Bearsden, Glasgow G61 1HQ** to whom informal enquiries can be made on 041-339 8855 Extn 5819 or 6968. (4137)A

HERMANN-VON-HELMHOLTZ-PROGRAMM

Der Bundesminister für Forschung und Technologie gewährt im Rahmen des Förderprogramms

NEUROBIOLOGIE

besonders qualifizierten deutschen Nachwuchswissenschaftlern, die nach einem mindestens einjährigen Forschungsaufenthalt im Ausland nach Deutschland zurückkehren möchten, zeitlich befristete Forschungsbeihilfen. Die Forschungsbeihilfe wird in der Regel für 2 Jahre vergeben. Sie umfaßt eine Stelle vergleichbar BAT IIa/Ib und einen Pauschalbetrag für Sachmittel. Die Vergabe der Forschungsbeihilfen erfolgt auf Grund eines Auswahlverfahrens nach wissenschaftlichen Gesichtspunkten. Ein Merkblatt über Forschungsbeihilfen und Antragsformulare können bei der zuständigen Geschäftsstelle.

Naturwissenschaftliches und Medizinisches Institut
an der Universität Tübingen in Reutlingen (NMI)
Gustav-Werner-Str. 3, 7410 Reutlingen

angefordert werden. Forschungsbeihilfen werden erstmalig ab 01.01.91 vergeben. (W7541)A

ASSISTANT PROFESSOR

Department of Structure and Chemistry of Biopolymers
Bayreuth University

Two full-time positions on the assistant professor level are available immediately in the field of NMR of biomolecules. Both positions are for 3 years initially (renewable), one of them is tenure track. Areas of interest include structure determination of proteins (kinases) and synthetic peptides. The department is planning to have a 600 MHz spectrometer installed in early 1991. Adequate computing and biochemical facilities are available. The successful applicants are expected to have postdoctoral training in the field of structural NMR and/or protein chemistry.

Salaries are according to the German government salary scale and depend on age and marital status.

Please forward applications including a cv and a list of publications to **Professor Paul Rösch, Lehrstuhl für Struktur und Chemie der Biopolymere, Universität Bayreuth, Postfach 10 12 51, D-8580 Bayreuth, FRG.** (W7544)A

Imperial College of Science, Technology and Medicine
Department of Biochemistry

Molecular Genetics of Neural Development

MRC-funded position available for a post-doctoral research assistant to study the molecular basis for developmental decision making processes during Drosophila neural development with Dr David Hartley. By a combination of genetic, molecular and cell biological techniques, we hope to understand the dynamic interplay between the cell surface and the nucleus which permits the developing nerve cells to distinguish and react to extrinsic cues. The research assistant will be involved in the identification, phenotypic characterization and eventual cloning of genes which regulate developmental choices of incipient nerve cells.

Salary on IA scale £10458-£16665 (under review) plus £1767 London Allowance.

Experience in genetic and/or molecular biological and/or cell biological techniques is an advantage. Applicants should send a CV with names, addresses and phone numbers of two referees, to **Dr D Hartley, Department of Biochemistry, Imperial College of Science, Technology and Medicine, London SW7 2AZ.** (4132)A

International Rice Research Institute

Deputy Director General for Research

The International Rice Research Institute seeks a Deputy Director General for Research. The position becomes vacant in May 1991.

IRRI IRRI is an international, non-profit, agricultural research institute funded by some 30 donor nations and organizations. Its goal is the enhancement of rice production and sustainability to benefit the world's 3 billion people who are dependent on rice for their livelihood and as their basic food.

Responsibilities

- Provide leadership in the establishment of research priorities and the application of innovative scientific approaches to address problems of increasing the productivity and sustainability of rice-based systems.
- Direct IRRI's multi-disciplinary research programs and discipline-oriented research divisions.
- Enhance ties with advanced agricultural research institutes.

Qualifications

- PhD, with extensive experience and a record of high quality agricultural research.
- Sound knowledge of and experience with agriculture in the developing world.
- Vision and research leadership, ability to communicate with and inspire high performance from scientists of different nationalities and disciplines.
- Proven record in research management and administration.
- Fluency in written and spoken English.

Benefits Salary and perquisites are competitive with those of similar international institutions. The Deputy Director General for Research will live at IRRI headquarters in Los Bañoc, Laguna, 60 km south of Manila, Philippines.

Interviews Interviews of short-listed applications will commence in September 1990.

Apply to Applications with full documentation, including the names and addresses of three referees, and names of nominees should be addressed to Dr. Klaus J. Lampe, Director General, IRRI, PO Box 933, 1099 Manila, Philippines. Phone (63) 2-818-1926; FAX (63) 2-818-2087.

(W7530)A

UNIVERSITY COLLEGE
& MIDDLESEX
SCHOOL OF MEDICINE

Professor and Head of the Department of Medicine

Applications are invited for an established Chair of Medicine with the appointee assuming the headship of the Department of Medicine on the retirement of Professor S.J. Semple in September 1991.

Applicants should have a strong commitment to undergraduate and postgraduate teaching and a personal record of distinction in research. The Department of Medicine has academic activities in association with The Middlesex, University College and Whittington Hospitals; no specific speciality interest of applicants is being sought.

Applications including a full curriculum vitae and the names of three referees should be sent within 4 weeks of the appearance of this advertisement to the Provost, University College London, Gower Street, London WC1E 8BT. Further particulars about the post are available from the **Dean, University College and Middlesex School of Medicine, Riding House Street, London W1P 7PN** (Tel: 071-380 9306). *Equal Opportunities Employer.* (4119)A

UCL

Nestlé

Would you like to use your scientific background within an international food company? Are you looking for a position where you can use your negotiating talents and your sense of diplomacy?

Our legislation Department is seeking a

BIOTECHNOLOGIST (MOLECULAR BIOLOGY AND GENETICS)

or

ENGINEER IN ENVIRONMENTAL SCIENCES

or

FOOD TECHNOLOGIST

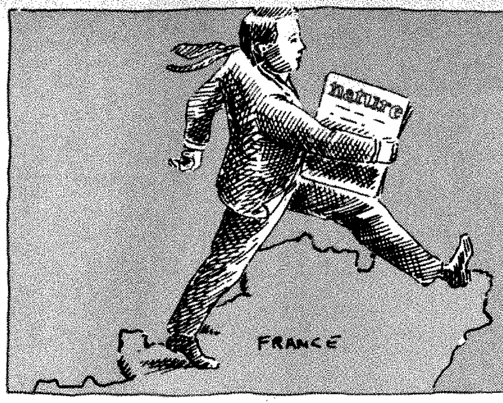
who will be responsible for

- the supervision of the development of food legislation at a national and international level in the above fields
- active participation in the preparation of new legislative texts
- assistance to the international headquarters in Vevey and to operational companies abroad.

For this position we require:

- University degree in biotechnology, environmental sciences or food technology
- Several years experience in the above fields
- Knowledge of French, English and German
- Good negotiating and communication skills.

Kindly forward your application, accompanied by the usual documents to: **Mr. E. Brambilla, Personnel Department, Nestlé, 1800 Vevey.** (W7558)A



SCIENCE IN FRANCE

Au coeur de la santé

ICGM PRACTICAL COURSES

EPITOPE MAPPING USING BACTERIAL EXPRESSION VECTORS

PARIS September 10-21 1990

Organizers:

Keith STANLEY (Sydney)
George BANTING (Bristol)
Richard BENAROUS (Paris)

The course will be based on the epitope mapping technology developed at EMBL by Keith Stanley and coll. (EMBO J. (1987) 6, 1951-1957).

Course objectives:

1—**Construction of epitope libraries from participant's cDNA**. This will be fragmented and cloned into pEX627.

2—**Screening of the epitope library** and colony purification. Participants should bring their own polyclonal serum or monoclonal ascites.

3—**Sequencing of positive clones.**

Maximum number of participants: 20 Course fees: 9000 french francs, lunches included but not accommodations.

Registration deadline **10 August.** Application forms are available from: **Dr Richard Benarous ICGM 22 rue Mechain 75014 Paris France.** Telephone: 33 (1) 40 46 04 11. Fax: 33 (1) 40 51 77 49. (W7539)C

BIOMAT '90
POLYMERS AND IMMOBILIZED CELLS OR BIOMOLECULES
Fundamentals and Applications
December 12-14 1990
BORDEAUX, FRANCE

The general objective of this meeting is to enlarge the usual biomaterial area, ie design, processing, characterization, application for medical devices and functional assistance, to more general aspects of interactions of biomaterials with biological systems, and to various issues of related studies. The following list of topics correspond to this intention.

Hybrid biomaterials; Bio artificial organs; Bioactive polymers; Drug delivery systems; Biosensors; Affinity matrixes; Biotechnology; Biological reagents.

Applications to:- **M. Charles BAQUEY, BIOMAT '90, INSERM U 306, Université de Bordeaux II, 146, rue Léo Saignat, 33076 BORDEAUX Cedex.** Tel: (33) 56 93 12 711. Fax: (33) 56 24 94 65. (W7525)C

X e Colloque de la Société Française de Biologie du Développement (SFBD)

5-8 septembre 1990 à Banyuls-sur-mer.

Thèmes: Cycle cellulaire et Développement précoce; Génétique et Neurogenèse; Communications libres.

Information et Inscription: Observatoire Océanologique (Laboratoire Arago), H-J. Marthy, 66650 Banyuls-sur-mer. Tél. 68 88 00 40; Fax: 68 88 16 99. (W7523)C

Important private Medical Research Center in the Paris area, member of one of the leading pharmaceutical companies in France is hiring for its

DEPARTMENT OF CELLULAR AND MOLECULAR BIOLOGY

Two Senior Researchers in Biology/Biochemistry

(PhD. or post-doctoral level)

The successful candidates have a good experience in mRNA isolation, protein purification, Northern and Western blot and are creative and independently working individuals. They are interested in the isolation and characterization of transport proteins or the expression of oncogenes.

Please submit CV to Média-System, 6 impasse des Deux Cousins, 75849 Paris Cedex 17 France. Please quote reference 2044 on the envelope.

Eighth National Meeting of the French Society for Mass Spectrometry

19-21 September 1990

University of Nice - Sophia Antipolis, Nice, France

This meeting will be organized by the FT-ICR Group at the University of Nice Sophia Antipolis under the auspices of the French Society for Mass Spectrometry (SESM) and the Mass Spectrometry Group of the French Society for Chemistry (SFC) in connection with the CNRS and the GAMS. The scientific program will cover all aspects of Mass Spectrometry. Plenary and keynote lectures will be given by invited speakers covering the latest advances in the field, in particular:

- Hyphenated techniques: TG-MS, ICP-MS, SFC-MS.
- Ionization methods: laser, ion spray, API, FAB and FT-ICR.
- Instrumentation: ion trapping techniques, TOF.

Applications of Mass Spectrometry to Biochemistry, Flavours and Fragrances and Geochronology will be among the topics.

Further details are available from:

Dr. P.-C. MARIA, GROUPE FT-ICR, Laboratoire de Chimie Physique Organique, Université de Nice – Sophia Antipolis, Parc Valrose, 06034 NICE Cédex, France. Tel: (33) 93 52 98 52. FAX: (33) 93 52 99 19. (W7545)C

UNIVERSITÉ DE BESANÇON

Department of Biochemistry and Molecular Biology

The Science Faculty of Besançon (France) invites applications for a position of Professor of Molecular Biology

The professor will have to teach Molecular Biology and will have to conduct research concerning the modification of monoclonal antibodies by using gene manipulation techniques. This research programm is supported by the CNRS.

Applicants should have a very good record of research achievement in Molecular Biology, and are expected to be able to teach in French. The post will be available in October 1991.

Applications including a C.V., a list of publications, the names of two referees and two reprints of the three most important publications should be submitted to: **Professor Y. Gaudemer, Laboratoire de Biochimie – Biologie Moléculaire, UFR Sciences et Techniques, Route de Gray, 25030 Besançon Cedex – France.** Phone number: 81.66.62.44.

(W7521)A

The Research Division in RHEUMATOLOGY of an important pharmaceutical research center located in **PARIS suburb**

is looking for

A research worker in cell culture and bone tissue

The profile : a graduate from university (third cycle) if possible and Post-Doctorate having good knowledge in bone biochemistry.

Interested by the creation of knew molecules, particularly for the treatment of osteoporosis.

He will take in charge the culture unit within a young team of research working on bone metabolism.

Thanks for sending a manuscript letter, C.V. and claims to *PUBLIVAL/7002* - 27 Route des Gardes, 92190 MEUDON (FRANCE).

recherche un
INGENIEUR D'APPLICATIONS

pour renforcer l'équipe Tripos basée à Palaiseau (91).

Chercheur expérimenté dans le domaine de la Modélisation Moléculaire, vous souhaitez travailler au sein d'une équipe dynamique en liaison avec nos autres centres européens et notre siège aux Etats-Unis.
En contact permanent avec plus de 40 sites utilisant le logiciel Sybyl en France, la relation avec nos clients est primordiale. Anglais indispensable.

Rémunération motivante, voiture de fonction.

Adresser CV et prétentions à **Evans & Sutherland, 3, Allée des Garays 91124 Palaiseau Cédex** ou contacter S.Briggs au 33.1.69.20.46.47. (W7547)A

NATO Advanced Research Workshop

GENOME ORGANIZATION AND EVOLUTION

Spetsai, Greece
15-19 September, 1990

A NATO Advanced Research Workshop on Genome Organization and Evolution will take place in the island of Spetsai, Greece, between September 15-19, 1990.

A partial list of speakers includes: W. Arber (Basel), G. Bernardi (Paris), T. Bettecken (Würzburg), R. J. Britten (Corona del Mar), M. Burmeister (San Francisco), G. Dover (Cambridge, U.K.), B. Dutrillaux (Paris), W. Fitch (Irvine), C. Gautier (Lyon), J.H. Gillespie (Davis), M. Gouy (Lyon), G. Holmquist (Duarte), T. Ikemura (Mishima), T. Jukes (Berkeley), J. Jurka (Palo Alto), W.-H. Li (Houston), G. Macaya (Paris), D. Mouchiroud (Lyon), J.-C. Mounolou (Orsay), M. Nei (Houston), T. Ohta (Mishima), E. Olmo (Naples), G. Roizès (Montpellier), C. Saccone (Bari), M. Schmid (Würzburg), V. Sgaramella (Pavia), P. Sharp (Dublin), V. Stingo (Naples), A.T. Sumner (Edinburgh), E. Zuckerkandl (Palo Alto), and H. Zuber (Zürich).

Persons interested in participating in this Workshop should send a brief curriculum vitae, a list of publications, a statement on their research interests and, if they so wish, an abstract of their oral or poster presentation to **G. Bernardi, Laboratoire de Génétique Moléculaire, Institut Jacques Monod, 2 Place Jussieu, 75005 Paris, France, Fax 33-1 46 33 23 05, before August 15.** Accepted participants will have to take care of their travel expenses and living expenses (the latter amount to about 150 USD). A number of Fellowships to defray such costs will be available for young participants.

SEILLAC 1989

SECOND INTERNATIONAL CONFERENCE ON BISPECIFIC ANTIBODIES AND TARGETED CELLULAR CYTOTOXICITY

Seillac, France. October 9-13, 1990.

The first International Conference on Biospecific Antibodies was held in Annapolis, MD, on October 22-25, 1989. The studies which were presented there helped to greatly increase our understanding of the cytotoxic potential of effector cells, most notably T cells and macrophages, which have been triggered by bifunctional antibodies.

The 2nd International Conference will further our objective to bring together basic researchers, clinicians, and representatives of commercial organizations to present their most recent results using bispecific antibodies for medical and research purposes. The format of the meeting will be similar to that followed in the Annapolis conference: there will be oral presentations by selected speakers as well as poster sessions. This meeting will provide a solid base of information useful for the design of bispecific antibodies to direct the cytotoxic potential of monocytes, PMN, NK cells, and T cells for therapy of cancer and infectious disease. The second conference will also present an excellent opportunity for participants to review all ongoing clinical protocols using targeted cytotoxic cells.

As in last year's meeting, the 2nd International Conference will accommodate a small number of registrants — approximately 120 people. Participants will include teams of established investigators as well as scientists who have recently entered the field.

The 2nd International Conference will take place at Le Château de Seillac, located in the Loire Valley. This area is well known for its rich historic heritage, as well as for some of the finest wines of France. All participants will be housed in the Château or in one of the condominiums located on the castle grounds. Lodging will be arranged by the Organizing Committee at Centre National de Transfusion Sanguine (CNTS) PARIS.

Au cœur de la Santé

ROUSSEL UCLAF, groupe pharmaceutique et agrochimique français à vocation internationale intervient dans trois secteurs d'activité : Santé humaine, végétale et animale.

Présentes dans le monde entier, nos équipes de recherche, développement, fabrication, marketing et vente démontrent chaque jour leur compétence et leur volonté de progresser.

Dans le cadre de notre développement, nous recherchons un

CHEF DE LABORATOIRE EN PHARMACOLOGIE

Au sein du département «endocrinologie» vous serez chargé d'animer et de coordonner une équipe de recherche fondamentale de 4 personnes opérant dans les domaines suivants :

- *Recherche d'applications thérapeutiques sur des anti-hormones dans le domaine des stéroïdes.*
- *Mise au point de nouveaux modèles d'expérimentation.*
- *Rédaction et présentation des dossiers pharmacologiques.*
- *Echanges pluridisciplinaires au sein du groupe et participation aux congrès traitant ce sujet.*

Docteur en pharmacologie avec de préférence une spécialité en endocrinologie, vous avez 3 à 5 ans d'expérience dans le domaine de la recherche.

La pratique de l'anglais est impérative.
Le poste est basé à Romainville (93).

Si cette opportunité vous intéresse, nous vous remercions d'adresser au plus tôt lettre manuscrite, CV et prétentions sous référence 122G à SWITCH 40, rue Amelot 75011 PARIS qui traitera votre dossier en toute confidentialité.

AFFLUENTS

INSERM PARIS

Neurodegenerative Disease Unit

3 Years Postdoctoral Fellowship (Electron Microscopist)

Applications are invited for the post of full time researcher to support a group of 35 persons working on the mechanism of cell death in Parkinson's and Alzheimer's disease.

The postholder will be responsible for the management of the electron microscope and ultramicrotome. The applicant should be able to conduct a research project and teach EM techniques to the other members of the team.

Experience in thin sectioning of biological material, and immunohistochemistry techniques at the EM level is required. In addition, experience in managing EM facilities and image analysis is desirable. Knowledge of the central nervous system ultrastructure would be an advantage.

Appointment will be made for a period of 3 years starting as soon as possible. Salary will depend on experience.

Applications, together with C.V., list of publications and names and addresses of two referees, should be sent to: *Dr. AGID, INSERM U289, Hôpital de la Salpêtrière, 47 bd de l'Hôpital, 75013 Paris, France or Fax (33) 1 44 24 36 58.*

NEW ZEALAND DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

DSIR Chemistry

Research Associates New Zealand

DSIR Chemistry is a large division of a New Zealand Government Department located at Lower Hutt, undertaking basic and applied research as well as commercial contracts.

Applied Protein Chemistry

Functional modification of proteins and/or the application of enzymes as catalysts as part of an Industrial Biocatalysis programme. Contact: Dr. R H Furneaux.

Atmospheric Trace Gases and Aerosols

Atmospheric trace gas or aerosol analysis as part of the clean-air monitoring programme currently being run at Baring Head, New Zealand, in collaboration with the DSIR Institute of Nuclear Sciences and the New Zealand Meteorological Service. Contact Dr. A L Dick.

Ceramic Coatings

Ceramic coatings involving sol-gel or metal-organic ceramic precursor synthesis. The programme complements existing programmes in Engineering Ceramic synthesis, fabrication and characterisation. Contact Dr. I W M Brown.

Dioxins in Pulp/Paper

Investigate the sources of, and mechanistic routes to, dioxin formation during pulp bleaching and paper production. Contact Dr. D Hannah.

Polysaccharide Structure

Development of new techniques and their application to commercially interesting algal, animal, bacterial and plant polysaccharides from New Zealand agricultural resources. Contact Dr. R H Furneaux.

Applicants for these positions should have a PhD and relevant experience. The positions are for one year, renewable by mutual agreement. Salary will be in the range of NZ$30,000-40,000 per annum, with assistance for travel and relocation.

Enquiries should be made to the contact named above,
DSIR Chemistry,
Private Bag, Petone,
New Zealand,
Telephone 64 4 666-919, facsimile 64 4 694-500.

(W7519)A

THE UNIVERSITY OF LEEDS
Department of Biochemistry and
Molecular Biology

CHAIR OF BIOCHEMISTRY

Applications are invited for the established Chair of Biochemistry which will become available on the retirement of Professor Donald S Robinson in September 1990. This prestigious Chair will be held in major new department, formed by the merger of the present separat Departments of Biochemistry and Biophysics. Applicants who hav an international scientific reputation in any area of biochemistry o molecular biology will be considered. The salary will be within the non-clinical professorial range.

Further particulars may be obtained from the **Registrar, The University, Leeds LS2 9JT** (tel 0532-333969) quoting reference numbe 83/102. Applications (2 copies) stating age, giving details of qualifications and experience, naming three referees and providing a statement on how, if successful, the applicant would envisage fulfulling the requirements of the post should reach the Registrar not later than 14 September 1990. Applicants from overseas may apply in the first instance by telex (556473 UNILDS G) or facsimile (0532-336017 or 0532-334123), naming three referees, preferably at least one in the United Kingdom.

The University of Leeds is an equal opportunities employer

(4001)A

UNIVERSITY OF CAMBRIDGE
SCHOOL OF CLINICAL MEDICINE

Cytogeneticist/Research Assistant

Salary £11,088-£12,381

To join a molecular biology group investigating the role of chromosome 21 genes to the genetic disorders of Down syndrome and Alzheimer's disease. The work will entail mapping genes derived from embryonic brain cDNA libraries to metaphases of human chromosome 21 and mouse chromosome 16.

The Research group is actively searching for the genes involved in Alzheimer's disease and Atrioventricular Septal Heart Defect. Our gene cloning work has progressed to isolating a number of candidate genes which are being assessed anatomically by 'in situ' hybridisation and immunocytochemical analysis. We are looking for a cytogeneticist/research assistant with expertise in metaphase 'in situ' hybridisation to further our range of analysis and who will enjoy working within this integrative research approach to clinical disorders.

Applications should be forwarded to **Dr. Sarah-Jane Richards, Department of Medicine, Level 5, Addenbrooke's Hospital, Cambridge CB2 2QQ.**

The University follows an equal opportunities policy. (4131)A

INSTITUTE OF PSYCHIATRY
Department of Neuroscience

MOLECULAR BIOLOGY OF ALZHEIMER'S DISEASE
POSTDOCTORAL or GRADUATE RESEARCH ASSISTANT

A vacancy exists for either a postdoctoral fellow or graduate assistant (registration of PhD will be expected), depending upon the suitability of applicants, for a project on abnormal phosphorylation of microtubule associated protein tau. The work involves protein isolation, characterization, monoclonal antibody production and DNA cloning. The appointee will work with a technician on the same grant and in a multidisciplinary group studying neurodegenerative disease. The project is funded by The Wellcome Trust for 3 years and as such postdoctoral appointees will be eligible for a Wellcome Trust salary enhancement. (Salary range 1B £12,225-14,148; 1A £14,148-18,432 inclusive of London allowance. Prospective candidates are invited to contact Professor B H Anderton (071-703-5411 ext 3259).

Applications in the form of a CV including the names and addresses of two referees should be made to the **Personnel Office, Institute of Psychiatry, De Crispigny Park, Denmark Hill, London SE5 8AF** (Tel 071 703 5411 ext 3164) from whom further particulars may be obtained. (4149)A

Postdoctoral Position to study Varicella Latency and Gene Expression

Immediate opening for an individual with strong training in molecular virology-genetics to collaborate with a team studying varicella virus latency and gene expression.

Send curriculum vitae and names of three references to:

Dr. Donald H. Gilden, Professor and Chairman of Neurology

AA/EOE (NW5528)A

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF BIOLOGY

POSTDOCTORAL POSITION IN NEUROBIOLOGY

Applications are invited for a postdoctoral research position in Neurobiology, funded through the SERC Invertebrate Neuroscience Initiative. The project concerns the physiology, pharmacology and development of synapses which are made between identified neurones associated with the simple eyes of the locust. The successful applicant will join an active team which is involved in research into the mechanisms by which sensory information is processed within the insect optic lobes and ocellar pathways.

The position is tenable for two years, commencing between October 1990 and March 1991. Salary will be up to £14,703 per annum on the Grade 1A salary scale (£10,458-£16,665) according to qualifications and experience.

Enquiries and applications, which should include a curriculum vitae and the names and addresses of two referees, should be sent to **Dr. P. J. Simmons, Department of Biology, Ridley Building, University of Newcastle upon Tyne, NE1 7RU** (Tel: 091 222 6457, Fax. 091 261 1182) to arrive not later than 10th August 1990. (4146)A

SENIOR DIRECTOR

RESEARCH AND COLLECTIONS

This preeminet cultural and educational institution seeks a scientific visionary to exploit and influence its collection-based research and in so doing, raise its profile to that of a world leader. Under a new corporate mandate, the organization is pursuing a level of excellence in science that will guide the way into the next century.

As the Senior Director for Research and Collections, you will provide the leadership to forge comprehensive research programmes which will serve to understand the evolution, diversity and interrelationships of plants and animals, and the composition and evolution of the earth. Reporting to the institution's Director/Chief Executive, you will also be responsible for the development and preservation of collections of animals, plants, rocks and minerals for biological and geological research. You will explore the frontiers of knowledge where society's needs are greatest, and disseminate intelligence to science, government and the general public with the goal of enhancing the balanced relationship between man and nature.

You are a high-profile professional who brings to the position a doctorate, preferably in biology or geology, several years experience in leading-edge scientific research and a broad familiarity on subject of natural history. A seasoned leader, you are are bilingual have superior interpersonal abilities and well-developed communications skills.

If you possess the vision and drive to meet this unique challenge, please reply by 30 July, giving full personal details, quoting File No. E90603. Location: Ottawa.

The University of Glasgow
Department of Veterinary Pathology
Research Assistants in Molecular Virology

The following positions in molecular virology are available for 3 years from July 1990. Applications are invited from recent graduates with good degrees in molecular biology, virology or a related discipline. The appointments will be on the 1B Scale starting at £11,399 p.a.

(1) Development of Recombinant Vaccines to Equine Herpesviruses

Two research assistants are required to assist a group of 3 postdoctoral scientists developing vaccines to equine herpesvirus through deletion of genes affecting virulence. This group has been actively involved in the molecular biology of Equine Herpesviruses for several years and the work is now directed at producing a commercial vaccine. The successful candidates will be trained in the full range of molecular biology techniques.

(2) Characterisation of A New Retrovirus from Fish

A research assistant is required to characterise a new retrovirus isolated from fish. This project is part of a collaborative study with the Institute of Aquaculture at Stirling University, aimed at investigating the cause of a new epidemic disease of farmed fish in S.E. Asia. The Department of Veterinary Pathology has a major interest in the molecular biology and pathogenesis of retrovirus associated diseases. The successful candidate will be responsible for sequencing the genome of the new retrovirus isolate. Previous experience of techniques in molecular biology would be an advantage. Candidates, for this position, who possess a First Class Honours Degree will be permitted to register for a PhD.

Applications enclosing a full C.V. and the names of 2 referees should be sent to **Prof. David Onions, University of Glasgow Department of Veterinary Pathology, Bearsden Road, Bearsden, G61 1QH.** (4117)A

POSTDOCTORAL POSITION

Applications are invited for a postdoctoral position (2 years) in a research group studying genetics and regulation of virulence-associated properties in bacteria (*e.g. E coli* pili-adhesins, enterotoxins; for recent publications see: *Mol. Microbiol.* **3**, (1989) 1557. *Nature* **344**, (1990) 682).

PhD in biological sciences and experience in molecular genetics and biochemistry desirable.

Applicants should send curriculum vitae, statement of research interest, and a list of names and addresses of at least three references to:

Dr Bernt Eric Uhlin,
Department of Microbiology,
University of Umeå,
S-901 87 Umeå, Sweden (W7528)A

UNIVERSITY OF CAMBRIDGE
Assistant Director of Research in the Department of Physics

Assistant Director of Research in the field of Radio Astronomy to take up appointment from 1 October 1990, or as soon as possible thereafter. The successful candidate will engage in a strong programme of research in radio astronomy with the emphasis on experimental technique and will undertake teaching at graduate and undergraduate levels. The appointment will be for up to five years with the possibility of reappointment. The pensionable scale of stipends for an Assistant Director of Research, not ordinarily resident in College, is £14,169 a year, rising by nine annual increments to £20,469 (under review).

Further particulars may be obtained from the **Secretary of the Appointments Committee for the Faculty of Physics and Chemistry, Institute of Astronomy, Madingley Road, Cambridge CB3 0HA,** to whom applications (10 copies) including a curriculm vitae, the names, and addresses and telephone numbers of three referees and a full list of publications should be sent so as to reach him not later than 31 August 1990.

The University follows an equal opportunities policy (4150)A

WEST LAMBETH HEALTH AUTHORITY

St Thomas' Hospital

DEPARTMENT OF CLINICAL IMMUNOLOGY

MLSO 2

Salary Scale: £13,738-£17,579 inc.

Applications are invited from experienced laboratory workers for the above appointment in the Department of Clinical Immunology. This is a permanent appointment, and candidates will need to possess proven bench skills and good communication skills.

A successful postholder who could fulfil the responsibilities for training and development of laboratory staff should receive the award of two discretionary points. Opportunity is available for an appropriately qualified person to study for a higher academic qualification such as the Intercollegiate MSc in Medical Immunology or the MPhil degree by thesis. Attendance at management courses would be encouraged.

Ref: M/53.

MLSO I

Salary Scale: £10,464-£13,738 inc.

We are looking for a suitably qualified person to work in the Department of Clinical Immunology. This is a fully tenured and very interesting MLSO I*** appointment which carries the award of three discretionary points and we require someone who is well-motivated and enthusiastic.

The successful candidate, in addition to being involved in the routine laboratory investigations of the Department, will be expected to participate in training and in the evaluation of test procedures and reagents. The Department provides excellent facilities to gain further immunological experience and opportunities to obtain higher professional or academic qualifications such as the FIMLS or the MSc in Medical Immunology of London University.

Ref: M/54.

THE HOSPITAL IS WITHIN EASY WALKING DISTANCE OF WATERLOO AND WESTMINSTER STATIONS. WE OFFER AN INTEREST FREE SEASON TICKET LOAN SCHEME, SUBSIDISED MEALS AND SOCIAL CLUB.

FOR APPLICATION FORMS AND JOB DESCRIPTIONS please write to the Personnel Department, St Thomas' Hospital, London SE1 7EH, or telephone our 24 hour (Monday to Friday) answering service on 071-261 1185 quoting appropriate job title and reference.

Working towards equal opportunities. (4155)A

UNITED MEDICAL AND DENTAL SCHOOLS OF GUY'S AND ST THOMAS'S HOSPITALS

RESEARCH ASSISTANT

required in the Division of Anatomy at our Guy's Campus to work with Dr Caroline Wigley and Dr Jim Cohen on a project specifically concerned with cellular and molecular aspects of neuron survival and axon regeneration using tissue culture model systems and molecular techniques. This position is funded by the International Spinal Research Trust for three years in the first instance, starting from October.

Graduates in biological sciences with post-graduate experience in cell culture are welcome to apply. Further information contact Dr. Wigley (071-955 4410) or Dr. Cohen (071-955 4420). Salary on Research 1B scale £12,225-£13,503 inclusive depending on qualifications and experience.

Applications with full CV and the names and addresses of two referees to the **Personnel Officer, Staffing Office, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH** quoting reference G/ANA/577 by 27 July 1990. (4118)A

University of Waikato

Te Whare Wānanga o Waikato

Hamilton, New Zealand

Applications are invited for the following appointments:

LECTURER IN CHEMISTRY (Ref. A90/55)

Applicants should have a PhD or equivalent and preferably post-doctoral experience. Applicants are welcomed from specialists in any branch of the subject, but preference will be given to candidates with research interests in one or more of the following areas: Inorganic Chemistry; Analytical Chemistry; Industrial/Applied Chemistry. Information concerning the facilities available in the Chemistry Department and other enquiries of an academic nature should be addressed to the Chairperson, Associate Professor D W Smith (tel. (64) 71 562889 during business hours or fax (64) 71 560115).

UGC POSTDOCTORAL FELLOWSHIIP IN HONEY IDENTIFICATION (Ref. A90/33)

The Department of Chemistry and Biological Sciences invites applications for a University Grants Committee Postdoctoral Fellowship in Honey Identification. The appiontee would be expected to work on the development of a method of identification of the floral source of honeys by means of GC-MS analysis of trace organics. This would supplement the problematical method of pollen analysis currently used by the honey industry. The position will be available for a period of up to two years. Enquiries of an academic nature may be made to Dr A L Wilkins or Dr P C Molan (tel. (064) 71 562889; fax (064) 71 560115).

LECTURER IN PLANT MOLECULAR BIOLOGY (Ref. A90/57)

Applicants should have interests and experience in one or more of the following: developmental genetics of plants, molecular genetics of crop plants, primary and secondary plant metabolism, molecular basis of interactions between plants and other organisms. The Department of Biological Science has close links with agricultural research organisations and many opportunities exist to orient research towards the genetic improvement or basic metabolism of agricultural or horticultural crop species. The successful applicant is expected to teach in areas of genetics, biochemistry and botany according to his/her expertise. Enquiries of an academic nature may be made to Professor W B Silvester (tel. (64) 71 562889 during office hours or fax (64) 71 560115).

Current salary ranges per annum: Lecturer NZ$36,000-NZ$47,200; Postdoctoral Fellow NZ$36,000. Information on the conditions of appointment and method of application are available from the Academic Staff Registrar, University of Waikato, Private Bag 3105, Hamilton, New Zealand. (Tel (064) 71 562889, Fax (064) 71 560135). Applications quoting the appropriate reference number close **10 August 1990.**

Places for appointees children may be available in the creche run by the Campus Creche Society (Inc). The University welcomes applications from suitable people regardless of race, creed, marital status or disability. (W7531)A

Faculty of Agricultural and Environmental Sciences

Department of Plant Science

Macdonald College of McGill University

The Plant Science Department invites applications for a tenure track position, at the assistant professor level, in Sustainable Crop Production. Applicants must have expertise in an area of crop ecology. The preferred candidate should have a Ph.D. and postdoctoral experience in agricultural or related sciences with an interdisciplinary background. The successful candidate will be expected to teach at the undergraduate and graduate levels and develop a strong research program. Applicants should send a curriculum vitae and have three letters of reference sent to **Dr. Donald L. Smith, Plant Science Department, Macdonald College of McGill University, 21111 Lakeshore Road, Ste. Anne de Bellevue, Quebec, Canada, H9X 1CO** before November 15, 1990. (NW5530)A

POSTDOCTORAL RESEARCH ASSOCIATE

Brookhaven National Laboratory has a position available in the Medical Dept. for a recent Ph.D. trained in genetics and/or molecular biology. Experience in cytogenetic and molecular biology techniques, including DNA cloning and library construction, PCR, restriction and Southern analyses and in situ hybridization is required. Experience with mammalian/human tissue culture techniques is desirable. The work will include research on the molecular mechanism involved in the induction of cytogenetic effects by mutagenic/clastogenic agents, with emphasis on roles of replicative DNA polymerases and associated proteins. Interested candidates should contact Dr. M.A. Bender, Medical Department, Brookhaven National Laboratory, Associated Universities, Inc., Upton, L.I., NY 11973. *EOE M/F.* (NW5520)A

UNIVERSITY OF
Miami
SCHOOL OF MEDICINE

FACULTY POSITION IN MOLECULAR PHARMACOLOGY

he Department of Molecular and Cellular Pharmacology at the University of Miami School of Medicine is seeking applications for a tenure-track faculty position at the ASSISTANT OR ASSOCIATE PROFESSOR level. The position is available now at a rank and salary commensurate with experience. Generous lab space and start-up funds are available. Candidates must have a Ph.D. and/or M.D. degree, and an established record of research excellence involving molecular approaches to problems of pharmacological interest. The new faculty member will complement existing research efforts in the department, which include regulation of cardiac, smooth and skeletal muscle contraction, receptors and transmembrane signalling mechanisms, function and development of the nervous system, and regulation of gene expression.

Applicants should send a curriculum vitae, statement of past and future research interests, and the names and addresses of three references to **Dr. Lincoln T. Potter, Search Committee Chairman, Department of Molecular and Cellular Pharmacology, University of Miami School of Medicine, P.O. Box 016189, Miami, FL 33101.**

An Equal Opportunity/Affirmative Action Employer. (NW5518)A

DEOXYOLIGONUCLEOTIDE ANALOG DEVELOPMENT AND EVALUATION

Amgen has emerged as an innovative leader in the research and development of human therapeutics through applied biotechnology. As a result of our continued growth, we have opportunities available in Deoxyoligonucleotide Analog Development and Evaluation in our DNA Therapeutics Group, located in Boulder, Colorado, for the following positions:

RESEARCH SCIENTIST AND POSTDOCTORAL RESEARCH POSITIONS

The responsibilities of these positions include developing and executing new strategies for the characterization of the biological effects of oligodeoxynucleotide analogs in model systems.

Qualified candidates must have a Ph.D. in Biochemistry, Cell Biology, Virology or a related field. Supervisory experience is advantageous but not required.

Amgen offers an excellent compensation and benefits package and the unique opportunity to contribute to significant research programs on the forefront of biotechnology. If you feel that you have the necessary skills, qualifications and motivation and would like to be part of a company that places a high priority on its human resources, send a resume, in confidence, to:

AMGEN BOULDER, INC.
Department 2351
2045 32nd Street
Boulder, CO 80301

AMGEN

UNIVERSITY OF GLASGOW
Department of Zoology
TEMPORARY LECTURER

Applications are invited for the above post which is available for three years from October 1990. The position is funded by the Wellcome Trust under a Research Leave Fellowship grant. Applicants should have experience in biochemistry, immunology or related subjects and a research interest in parasitology. The successful applicant will be expected to carry out some teaching and administration for the Department of Zoology and research facilities will be available either within the Department of Zoology itself or in the Zoology Section of the Wellcome Laboratories for Experimental Parasitology, which is sited at the Veterinary School campus. Applicants are particularly sought to teach the biochemistry and immunology of parasite infections or vector biology, but this is negotiable. Starting salary will be from £12,792 to £14,744, depending on age and experience, with appropriate annual increments thereafter.

Applications including a curriculum vitae and the names, addresses and telephone numbers of at least two adademic referees should be sent to **Professor R.S. Phillips, Department of Zoology, University of Glasgow G12 8QQ** to whom informal enquiries can be made on 041-339 8855 Extn 4776. (4139)A

UNIVERSITY OF CAMBRIDGE
University Lecturer in the Department of Chemistry

University Lecturer in Inorganic Chemistry to take up appointment on1 October 1990, The person appointed will be expected to teach and conduct research in the borderline areas between main-group and transition-metal chemistry. The appointment will be for three years, with the possibility of reappointment to the retiring age.

The pensionable scale of stipends for an University Lecturer, not ordinarily resident in College, is £14,169 a year, rising by eleven annual increments to £21,852. There is no grade of Senior Lecturer.

Applications (ten copies), including a curriculum vitae, an outline of research intentions and names and addresses of three referees should reach **Dr. M. F. Ingham Secretary of the Appointments Committee for the Faculty of Physics and Chemistry, Institute of Astronomy, Madingley Road, Cambridge CB3 0HA,** before 10 August 1990. Further details are available

The University follows an equal opportunities policy (4148)A

BUNDESGESUNDHEITSAMT

MOLECULAR PARASITOLOGIST
ASSISTANT/ASSOCIATE PROFESSOR
SEARCH REOPENED

The Department of Zoology at the University of Georgia invites applications for a tenure-track position. Investigators working at the molecular/cellular level in any area of parasitology are encouraged to apply. Special consideration will be given to those with an expertise in areas such as recombinant DNA techniques and molecular separations. Departmental duties will include contributing to current teaching in parasitology to undergraduate students and developing a course in molecular parastiology at the graduate level. The successful candidate will have a prominent role in the Department of Zoology's current NIH training program in the molecular cell biology of parasites and vectors, and will be expected to develop a strong research program complementary to current departmental research which includes immunology, molecular biology, cell biology, biochemistry and ultrastructure of parasites. Current faculty are engaged in collaborative research in Brazil, Peru and Chile.

Send curriculum vitae; a statement of career objectives and current and planned research; and the names, addresses, and phone numbers of three or more references to:

Dr. Moises Agosin,
Chair, Search Committee,
Department of Zoology,
University of Georgia,
Athens, GA 30605,
Phone: 404-542-3439.

The University of Georgia

Applications received by September 15, 1990 are assured of consideration.

The University of Georgia is an Equal Opportunity/Affirmative Action Employer. (NW5515)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
MOLECULAR BIOLOGY OF TRANSLATIONAL CONTROL
DIVISION OF BIOCHEMISTRY

Two Posts are available, for a Postdoctoral Scientist and a Grade 4 Research Technician, to carry out a project in Dr M J Clemens' Laboratory, funded by The Wellcome Trust. The work will involve cloning and characterization of mRNAs with extensive secondary structure which may be important in the translational control of eurkariotic protein synthesis. Both posts are available from 1 October 1990 and will be for up to 3 years. Applicants should preferably have some experience in DNA cloning and/or sequencing techniques.

Postdoctoral salary up to £16,470 including London Allowance, Research Technician salary up to £10,171 including London Allowance, depending on age and experience (both scales currently under review).

To apply please send curriculum vitae and names of two referees to **Dr M J Clemens, Division of Biochemistry, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE**, from whom further information can be obtained (telephone 081 672 9944 ext 55762). Closing date 10 August 1990. Please quote reference 81/90. (4127)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF PROTEIN & MOLECULAR BIOLOGY

Molecular Mechanism of Nucleoside Transport

An enthusiastic **Postdoctoral Researcher** is sought to join a team investigating the mechanism of nucleoside transport across mammalian cell membranes, using both protein chemical and cloning strategies in newly purpose-built laboratories. The project involves collaboration with groups at the Universities of Cambridge and of Edmonton in Alberta, Canada. Experience in molecular biology, protein chemistry or membrane biology desirable. For further information, please contact **Dr. S. Baldwin on 071-794 0500 ext. 4201.**

This MRC funded position is available for 1 year with salary on the Research 1A Scale plus £1,767 London Allowance.

Full job description available from the **School Office, RFHSM, Rowland Hill Street, London NW3 2PF** (071-794 0500 ext. 4262) to which applications by curriculum vitae (two copies) plus names and addresses of two referees, should be sent by 26 July 1990. *Please quote ref: PMB/RF/118.* (4156)A

CHEMIST - INORGANIC/ PHYSICAL

AUS. $32,471 - $39,724 p.a.

If you are innovative, excited by new ideas, capable of solving complex problems, not afraid of making mistakes and know that you can rouse and generate interest in those working with you, then:

WE HAVE AN IDEAL OPPORTUNITY FOR YOU

This Division requires your innovative skills to enable it to contend with a range of problems and projects in timber preservatives and preservation processes and technology.

You will not only find ample scope for your creative capabilities, but you will become a vital member of an active research group. Your colleagues will be enthusiastic, similar-minded, friendly people at one of the Melbourne sites of our 300-strong, Australia-wide Divisions.

This position will require you to manage and work with a team to formulate, analyse and assess wood preservative chemicals, including complex metal systems and emulsion compositions. Close liaison and collaboration with other researchers in various wood products laboratories and especially with industry personnel, will enable you to put to use your strong interpersonal and communicative skills.

QUALIFICATIONS: PhD (or equivalent) in inorganic or metal complex chemistry is essential together with a first degree or equivalent in chemistry.

TENURE: Indefinite with Australian Government Superannuation Benefits available.

FURTHER INFORMATION: May be obtained by contacting Dr Harry Greaves on (613) 556 2218 or Facsimile (613) 543 6613.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience and the names of at least two professional referees are to be forwarded to:

The Chief,
CSIRO Division of Forestry &
Forest Products,
Private Bag No. 10,
Clayton, Victoria, 3168, Australia,
by 10th August, 1990.

UNIVERSITY OF ALASKA FAIRBANKS

SCHOOL OF FISHERIES AND OCEAN SCIENCES

Vacancy Announcement — External Vacancy
Faculty Tenure Track Position

TITLE AND RANGE:	Distinguished Professor of Fisheries Science School of Fisheries and Ocean Sciences, University of Alaska Fairbanks
SALARY:	$2100.80 Biweekly/DOE
JOB SUMMARY:	The University of Alaska Fairbanks is seeking applicants and nominations for the position of Distinguished Professor of Fisheries Science in the School of Fisheries and Ocean Sciences. The School is a newly-created unit, designed to integrate and enhance the fisheries and oceans programs within the University of Alaska. The position offers the opportunity to participate in its development and to provide intellectual leadership in this dynamic venture. As is usual for such senior positions, the successful applicant will be free to carve out his/her areas of emphasis from the numerous opportunities and challenges offered by Alaskan fisheries. He/she will assume a leadership role in fisheries research, teaching and public service for the new School, but will have considerable flexibility with respect to the specific activities. Fisheries is a dynamic area of science, and the School will be expanding its activities in a number of areas. There will be an opportunity to spend time at a number of off-campus sites in coastal areas of Alaska, and ultimately the permanent residence could be one of these locations. Initially, we plan to base the position at the Fairbanks campus.
SCHOOL SUMMARY:	The School of Fisheries and Ocean Sciences embraces the Institute of marine Science (which operates the Research Vessel *Alpha Helix*, the Seward Marine Center and the Kasitsna Bay Laboratory), the Juneau Center for Fisheries and Ocean Sciences at Auke Bay in southeast Alaska, the Fishery Industrial Technology Center in Kodiak, the Alaska Sea Grant College Program and the Marine Advisory Program. There are about 50 faculty, and an annual budget ranging from $15,000,000-$20,000,000.
QUALIFICATIONS:	The successful candidate will bring to the position a strong background in fisheries science and will have a distinguished record in university research and/or teaching, with a strong publication record appropriate to a leader in his/her field.
JOB DURATION:	Full time – Permanent.
APPLICATION:	APPLICANTS SHOULD SEND A STATEMENT OF INTEREST, A CURRICULUM VITAE, AND PROVIDE THE NAMES OF THREE REFEREES TO **CHAIRMAN, SEARCH COMMITTEE, OFFICE OF THE DEAN, SCHOOL OF FISHERIES AND OCEAN SCIENCES, UNIVERSITY OF ALASKA FAIRBANKS, ALASKA 99775-1080, USA. Telephone (907) 474-7531; FAX (907) 474-7204.**
OPENING DATE:	20 June 1990.
CLOSING DATE:	16 August 1990.

THE UNIVERSITY OF ALASKA IS AN EEO/AA EMPLOYER AND EDUCATIONAL INSTITUTION.

Persons hired by the University of Alaska must comply with provisions of the 1986 Immigration Control Act and are expected to possess a valid social security number.

Your application for employment may be subject to public disclosure should you be selected as a finalist.

(NW5523)A

Schering

Postdoctoral Fellow

If spearheading developments in allergy and immunology is what you have in mind, come to Schering-Plough Research.

Aggressive, goal-driven research gives Schering-Plough its competitive edge in the healthcare industry. But we need your progressive thinking to help effect significant breakthroughs in pharmaceutical research.

You will study the *in vivo* role of selected cytokines in immunologically-mediated disease. Exploring the mechanism of cytokine involvement involves employing molecular biological tools of PCR technology, *in situ* hybridization, and cellular immunology concurrent with the administration of anticytokine antibodies and cytokines by standard and novel means. Solid background in cellular immunology desirable. Additional skills in molecular biology would be a plus.

This position rewards talent with one of the highest stipends in the industry...unparalleled challenges... and the recognition for your ideas. For immediate response, please forward curriculum vitae to: Mr. G. Czuba, Schering-Plough Research, 60 Orange Street, Bloomfield, NJ 07003. We are an equal opportunity employer.

What you have in mind, we put in action.

Schering-Plough

FACULTY POSITIONS IN MOLECULAR NEUROBIOLOGY

THE OHIO STATE UNIVERSITY

The Biotechnology Center, in collaboration with academic departments within the Colleges of Biological Sciences, Medicine, and Pharmacy, invites applications for three joint tenure track faculty positions. Successful candidates will occupy new laboratories on the Neurobiology floor of the Biotechnology Center and join existing faculty whose research efforts focus on gene expression in nervous tissue during development and aging. This group will shortly expand to ten faculty. Applicants for **Assistant Professorships** should demonstrate exceptional potential to develop strong research programs that apply tools of molecular biology to address significant problems in neurobiology. Senior candidates with ongoing programs of excellence will be considered for an **Associate Professorship**. Qualified molecular neurobiologists working with vertebrate or invertebrate systems will receive careful consideration. Candidates who utilize transgenic mice in the course of their research are especially encouraged to apply. The Ohio State University is establishing an outstanding program in molecular neurobiology and neuroscience which is reflected by quality research facilities and highly competitive start-up funds and salary.

Screening of candidates will begin on August 15, 1990. Applicants should submit a curriculum vitae, statement of research plans, and names and addresses of three references to **Dr. Anthony Young, Chairperson, Molecular Neurobiology Search Committee, Ohio State Biotechnology Center, Rightmire Hall, 1060 Carmack Road, Columbus, Ohio, 43210.** *The Ohio State University is an Equal Opportunity/Affirmative Action Employer.* (NW5477)A

POSTDOCTORAL RESEARCH ASSISTANT 1A

Applications are invited from recent doctorates in isotope geology/igneous petrology to work on a NERC-funded project "Regional investigations of Andean magmatism by radiogenic-isotope geochemistry", involving mass-spectrometry, chemical analysis, and field work in South America. This post is available for up to three years from 1 January 1991 or ASAP thereafter. Applications with curriculum vitae and names of two referees, as well as requests for more details, to Dr. S. Moorbath, F.R.S. (0865-272035) by 30 September.

The University is an equal opportunity employer (4167)A

POST-DOCTORAL POSITION

The Department of Biochemistry and Cell Biology at RICE UNIVERSITY announces the availability of a post-doctoral position for biophysical and physiological studies of hemoglobins and myoglobins. Strong background in either rapid reaction techniques or molecular biology is desired. Projects will involve the construction, preparation, and characterization of site directed mutants. Available immediately. Salary will depend on experience. Send résumé and three letters of reference to **Dr. John S. Olson, Professor, Department of Biochemistry and Cell Biology, Rice University, P.O. Box 1892, Houston, Texas 77251.** *Rice is an Equal Opportunity/Affirmative Action Employer.* (NW5531)A

CASE Studentship

Investigations of the molecular dynamics of fluids by infrared and Raman spectroscopy

The relationship between molecular structure, flexibility and intermolecular interactions at the microscopic scale on the one hand and the bulk viscometric properties of liquids on the other hand is of great topical interest. In this project infrared and Raman spectroscopy will be used to study the relationship between the industrially important bulk properties (e.g. viscosity, elasticity) of model lubricants, and the dynamics and interactions of their constituent molecules. The most up-to-date equipment is available for spectroscopic studies at high temperatures and pressures, and for computer-aided molecular modelling.

Applicants should have a good honours degree (or equivalent) in Chemistry, Physics or Chemical Physics. SERC standard conditions plus an additional £750 per annum to the student. There will be an opportunity to work at a modern industrial research laboratory. Applications to **Dr. F. D. Wayne (051-373-5665)** at **Shell Research, Thornton Research Centre, P.O. Box 1, Chester CH1 3SH**; or **Dr. J. Yarwood (091-374-3136), Chemistry Department, Durham University, South Road, Durham DH1 3LE** as soon as possible. (4153)F

TWO CASE RESEARCH STUDENTSHIPS

A BIOCHEMICAL AND MOLECULAR APPROACH TO ELUCIDATE MICROBIAL ADAPTION TO EXTREME ENVIRONMENTS.

Universities of Aberdeen & Nottingham and Unilever Research

Applications are invited for two AFRC Cooperative Award Studentships. These studentships present a valuable opportunity to enter into a collaborative research programme between two Universities, Industry and the AFRC. Industrial preservation techniques are designed to stress microorganisms to the point of minimal survival. Microorganisms, however, have a wealth of genetic and biochemical defence mechanisms to promote their survival under stress. Understanding these mechanisms is essential if more effective antimicrobial strategies are to be developed.

Interested students with relevant qualifications should contact **Dr I Booth, Department of Molecular and Cell Biology, University of Aberdeen, Marischal College, Aberdeen AB91AS (Tel: 0224 273152)** or **Dr G Stewart, Department of Applied Biochemistry and Food Science, University of Nottingham, Sutton Bonington, Loughborough, Leics LE12 5RD (Tel: 0602 484848 ext 8370).** (4123)F

UNIVERSITY OF READING
DEPARTMENT OF MICROBIOLOGY

PhD Studentships

Applications are invited from individuals who possess or expect to obtain a 1st or upper 2nd class degree in Microbiology, Molecular Biology or a related subject, for the following studentships:

1. An MRC studentship to work with Dr. D. J. Evans on the structure/function relationships of the envelope glycoproteins of HIV, involving gene cloning and expression studies using the poliovirus system developed in Reading (Nature 322, 81-82 and 339, 385-388). Tel. (0734) 318893.
2. A Reading University studentship to work with Dr. P. Poole on the regulation of dicarboxylate oxidation in Rhizobium, involving the purification and cloning of malate dehydrogenase from both free-living and symbiotic species. Tel. (0865) 275306.

The Department has excellent facilities for advanced research and a lively research atmosphere, and will shortly be moving to new purpose built buildings as part of the School of Animal and Microbial Sciences.

Informal telephone enquiries on the indicated numbers are welcomed. Applications, including a CV with the names of two referees, should be made to the supervisors at the following address: **Department of Microbiology, University of Reading, London Road, READING, RG1 5AQ. (0734) 318901.** (4136)F

UNIVERSITY OF KENT
AT CANTERBURY ■■■■

PHD OPPORTUNITIES IN THE BIOLOGICAL LABORATORY 1990

Biochemistry Biotechnology Microbiology
Cell and molecular biology

The following Ph D studentships are available for October 1990

SERC Biotechnology directorate earmarked studentships

Protein engineering studies on the following of lysozyme (Professor R B Freedman)

Characterization of a thermostable lipase (Professor R B Freedman and K A Stacey)

SERC CASE studentships*

Biotreatment of pesticide residues in effluents (Dr R G Burns/A H Marks Ltd)

The genetics of production of a secondary metabolite by a pseudomonad (Professor K A Stacey/ICI)

SERC Quota studentships

Cell and molecular biology of the neuronal cytoskeleton (Drs A J Baines and M J Carden)

Molecular biology of protein secretion in bacteria (Dr T Hirst)

* These studentships carry an extra stipend from collaborating companies.

Applicants should have or expect to obtain by October 1990 a first or upper second class degree in a relevant subject. Please supply as soon as possible enclosing a brief c.v. to individual project supervisors from whom further information can be obtained.

Biological Laboratory, The University of Kent Canterbury, Kent CT2 7NJ.

KING'S COLLEGE LONDON
University of London

Protozoan Predation in the Rhizosphere

The rhizosphere is the interface between the plant root and the bulk soil: through it pass most of the mineral nutrients required by plants for growth and up to 40% of the photosynthetically-fixed carbon which is lost from roots. The rhizosphere, which is a region of high microbial activity, is therefore of intrinsic interest as a specialised ecosystem and an understanding of the processes that take place within it is of practical value in terms of increasing plant productivity and disease resistance in an environmentally acceptable manner. Of particular interest is the role of predatory organisms in the rhizosphere as they have potential as biocontrol agents.

Applications are now being sought from suitably qualified graduates (IIA or better in a science-based subject) to study protozoan predation in the rhizosphere. The project will involve establishing experimental microcosms at King's College and glasshouse experimentation at the Institute of Horticultural Research, Littlehampton. The successful applicant will join a team of scientists studying several aspects of the rhizosphere, attend international meetings and visit collaborators in overseas laboratories. The studentship attracts a supplement of £1250 in excess of basic stipend.

Enquiries should be accompanied by a c.v. and the names of two referees and should be sent as soon as possible to: **Dr. M. Bazin, Division of Biosphere Science, King's College London, Campden Hill Road, London W11 7AH.** (4147)F

2 Postdoctoral Research Fellowships

ION CHANNEL STRUCTURE AND MECHANISMS

Applications are invited from Post-doctoral (or near-Postdoctoral) scientists to work for 3 years in the laboratories of Richard Ashley and David Hulmes. Both positions are funded on the AR1A scale. One post is supported by the British Heart Foundation as part of a multi-disciplinary approach to investigate pore conformations of the cardiac calcium release channel. A second post (funded by the Wellcome Trust) is for work on a novel brain calcium channel involved in calcium signalling. We routinely use a number of different techniques and hope to attract candidates from a very wide range of backgrounds including electron microscopy of macromolecules, molecular biology and electrophysiology. Further written details about each post and about the Department of Biochemistry are available from the **Personnel Office, 63 South Bridge Edinburgh EH1 1LS,** with whom applications by letter, including c.v. and the names and addresses of two referees, should be lodged by 31st August 1990. PLEASE QUOTE REFERENCE NO. 5784. (4116)E

SEEDS OF TOMORROW THROUGH GENETIC ENGINEERING

Applications are invited for **junior or senior fellowships** available in the period October 1st, 1990 to September 30th, 1991 in the Training Network on Applications of Genetic Engineering and Molecular Biology for Seed Improvement.

This Network is hosted by the Commission of the European Communities and 50 laboratories in Plant Molecular Biology in the Member States.

Conditions: Ph.D. degree or equivalent.
The postgraduate research has to be carried out in a country different from the fellow's resident country.

For information on project opportunities and host laboratories write to:

Professor Diter von Wettstein
Department of Physiology
Carlsberg Laboratory
Gamle Carlsberg Vej 10
DK-2500 Copenhagen Valby

NUROFEN

(4163)E

KING'S COLLEGE SCHOOL OF MEDICINE AND DENTISTRY
of King's College London
Department of Immunology

RESEARCH FELLOW IN IMMUNOLOGY OF HIV INFECTION

Applications are invited for a three year research fellowship to undertake a study prospectively evaluating immunological and clinical parameters as guides to the management of patients with human immunodeficiency virus (HIV) infection. The post is based in the Department of Immunology where the successful candidate will investigate various aspects of immune functioning in more than 150 HIV-positive patients. The post would suit someone keen to develop research experience and work towards an academic career. The successful applicant will be joining a stimulating group of collaborators and will be expected to participate in the research activities of the department.

Salary will be based upon the NHS Registrar scale or the equivalent non-clinical scale. For further details and informal discussions please contact Dr. M. Peakman on 071-326 3588. Applications in the form of a full curriculum vitae and the names and addresses of two referees should be sent to the **Secretary of the School, King's College School of Medicine and Dentistry, Bessemer Road, London SE5 9PJ** by 27th July 1990. (4115)E

UNIVERSITY OF OXFORD MERTON COLLEGE

Junior Research Fellowships 1991

The College proposes, if candidates of sufficient merit present themselves, to elect in 1990 to two or three Junior Research Fellowships. These Fellowships are open to both men and women. Candidates must not have accumulated more than six years in post graduate study or research by 1 October 1991.

Details of the awards and of the method of applying for them may be obtained by writing to the **Warden's Secretary, Merton College, Oxford, OX1 4JD.** Closing date for applications is Friday 5 October 1990. (4122)E

EMBO

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY

AUTUMN 1990 AWARDS

Next deadline: 15 August 1990

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are usually awarded initially for one year, but with the possibility of renewal for a second year. In cases of exceptional scientific merit, however, the selection committee can award a 2-year fellowship. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 15 August 1990. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 29 October 1990.

Application forms and further details may be obtained from **Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40,69 Heidelberg 1, F.R. Germany.** Inquiries should be accompanied by a self-addressed adhesive label. (W7235)E

ASSISTANTSHIPS

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF ZOOLOGY

Postdoctoral Research Assistant

Applications are invited for a three year postdoctoral research assistantship funded by the MRC at the MRC Experimental Parasitology Research Group in the Department of Zoology. The project will involve the investigation of cytokine regulation during chronic infection with gastrointestinal parasitic nematodes and will focus on parasite factors responsible for interference in cytokine activity and downregulation of inflammatory and host-protective immune responses.

Candidates should possess a PhD or equivalent degree, should have an interest in parasitic infections and above all should be self-motivated and prepared to work in a multidisciplinary research group. Previous experience in cellular immunology, particularly in the measurement or evaluation of cytokine activity would be an advantage.

The salary will be in the 1A range £10,458-£11,736 pa (under review).

Closing date is 6 August 1990 and the appointee should be prepared to commence work soon afterwards. Enquiries and applications, including a comprehensive CV and the names of two referees, should be addressed to **Dr J M Behnke, Department of Zoology, University of Nottingham, Nottingham NG7 2RD.** (4143)P

DYSON PERRINS LABORATORY
DEPARTMENTAL ASSISTANTSHIP

The biosynthesis of ß-lactam antibiotics is the focus of a multidisciplinary approach at Oxford, closely related to the recently established Oxford Centre for Molecular Sciences. Applications are invited from highly motivated biological scientists for a Departmental Assistantship, to work as part of the team working in this and related biosynthetic areas. Experience in enzymology and/or molecular biology is necessary. The successful applicant will be expected to contribute to the supervision of the group, as well as undertaking research studies. Salary is on the RS1A scale £10,458-£14,169 (under review) according to age and experience and will be for 3 years.

Applications for this pensionable post, including c.v. and the names of two referees, should be sent to **Professor J.E. Baldwin, Waynflete Professor of Chemistry, Dyson Perrins Laboratory, South Parks Road, Oxford, OX1 3QY.** Further particulars may be obtained through Oxford (0865) 275671. *The University of Oxford is an equal opportunities employer.* (4114)P

ANNOUNCEMENTS

British-Italian Collaboration in Research and Higher Education

Call for proposals

The Italian Ministry of Universities and Research in Science and Technology (MURST) and the British Council invite proposals under a new bilateral programme to promote scientific co-operation between research and higher education institutes in the two countries.

It is envisaged that most proposals will be for joint research projects of up to 3 years' duration in science, engineering, agriculture, social applications of science or medicine, or for collaborative action on professional formation, course design/validation or similar aspects of higher education in those areas. The programme will provide grants for a series of exchange visits, and key criteria for acceptance will be mutual benefit and the intention to develop long-term links.

Attention is also drawn to existing programmes aimed specifically at exploratory visits.

Closing date: 30 September 1990.

Further information and Notes for Applicants from:
Ufficio Relazioni Internazionali, MURST, Lungotevere Thaon di Revel 76, 00196 ROMA
Tel: (06)-3969941 Fax (06)-392209 Telex 612548 MUR 1

AGROECOLOGY AND CONSERVATION ISSUES IN TEMPERATE AND TROPICAL REGIONS

International Symposium

University of Padova, Italy, Department of Biology

September 26-29 1990

Topics of the Conference

- Animal and plant diversity and conservation
- Food web systems and energy flow patterns
- Plant and animal interactions
- Sustainable agriculture and farming conversion
- Agroforestry
- New trends in biological control practices
- Recovery and conservation of soil vitality
- Landscape ecology in agriculture
- Economy of agriculture ecosystems

A focus of the symposium will be to emphasize the interrelation and transfer of research and application in sustainability and environmental problems between temperate and tropical areas of the world.

290 people are attending from 42 countries. A limited number of posters is still accepted. Attendance is open: contact the Secretary by fax.

Organizing Committee

F. Golley, Athens, GE, UCA; G.G. Lorenzoni, Padova, Italy; O. Ferro, Padova, Italy; M.G. Paoletti, Padova, Italy; B.R. Stinner, Wooster OH, USA; L. Toniolo, Padova, Italy; A. INTERNATIONAL WEEKLY JOURNAL OF SCIENCE

MODERN MANAGEMENT OF HEADACHE

5th/6th November 1990, London

As the Cinderella of the Neurosciences, headache has had little attention paid to it and hardly any research was done on the subject. Three important advances have activated new interest: the new classification of headache; the long held theories of the pathogenesis of migraine have been challenged; and there are now new treatments based on specifically targeted receptors. This intensive course, given by specialists from the Charing Cross and National Hospitals will give the background to these advances, discuss the different types of headache and how new treatments are assessed. There will be patient demonstrations giving delegates a unique opportunity to hear about their symptoms and treatment.

This course will interest those seeking an update or rapid understanding of the modern management of headache, particularly clinicians, R&D personnel and those in marketing, product management and sales with responsibility for headache and migraine drugs.

This fluorescence polarity image of a fertilized sea urchin egg obtained with a Hamamatsu ultra-high sensitivity camera shows that the fluidity of the egg's plasma membrane decreases after fertilization. Photonics allows the study of these phenomena without destruction.

LIFE IS A PHENOMENON OF SUBSTANCE.

What makes Life? This is a question no longer to be left only to Philosophy, Theology, or indifference. Scientific research utilizing the principles of Photonics to determine the mechanisms and the reasons for thought, evolution, and for our very existence, will bring us hope, understanding, and Peace.

Teruo Hiruma

THE THIRD INTERNATIONAL CONFERENCE
PEACE THROUGH MIND/BRAIN SCIENCE

August 5th – 10th 1990
Hamamatsu, Japan

Aims of the Conference:

The brain is an organ which, in human beings, governs high-order mental functions such as knowledge, emotion and will. Study of the brain is viewed as forming one of the greatest frontiers upon which science and technology can throw light.

Further elucidation of the brain and mental functions must have a high impact on the advancement of science and technology, and hence open up the way to new developments in science. Moreover, this impetus would play an important role in deepening our understanding of the nature of human-beings, as well as a key role in contributing to world peace.

The aim of this conference is to apply new opto-science and technology to research on the brain and mental functions and thereby further advance this technology in the international world of science.

Presentations

The number of presentations will amount to approximately 30. (Sessions 1–6, Mon-Wed)

Participating countries:

America: The Soviet Union: Sweden: The United Kingdom: Canada: France: Japan: Others.

Attendees

Estimated number to total 200. (50 Non-Japan: 150 Japan)*
*Attendance is by invitation only.

Language:

English

Executive Committee:

Chairman Teruo Hiruma, President Hamamatsu Photonics K.K.; Kanji Torizuka, President, Fukui Medical School; Ken-ichi Uemura, Professor, Hamamatsu University School of Medicine; Yukio Tateno, Director, Division of Clinical Research, National Institute of Radiological Sciences.

International Science and Technology Courses

Advances in biotechnology: animal cell culture

16–27 September 1990, Canterbury.

Director: Dr. N. Jenkins, Lecturer in Biochemistry and Head of the Animal Cell Culture Unit, University of Kent.

Course fee: £985

★★★★

The Developmental and conservation of soil fertility

16–28 September 1990, Aberdeen.

Directors: Professor D. Atkinson, Professor of Land Resource, Professor J.W. Parsons, Professor of Soil Science and Oliver Brandon, Project Coordinator of the Aberdeen Centre for Land Use.

Course fee: £1080

★★★★

Environmental policy and management: an international forum.

7–14 November 1990, Alfriston, East Sussex.

Director: Brian D. Clark, Executive Director of the Centre for Environmental Management and Planning, Aberdeen University.

Course fee: £895

★★★★

Modern approaches to plant virology: virus transmission, detection and resistance.

17–29 March 1991, Dundee

Directors: Professor B.D. Harrison, CBE FRS, Head of Virology Department & Dr. A.T. Jones, Research Leader, Scottish Crop Research Institute.

Course fee: £1170

Recent advances in farming systems research: an international seminar.

2–12 April 1991, Edinburgh.

Director: Barry Dent, Professor of Rural Resource Management, Edinburgh School of Agriculture.

Course fee: £1260

★★★★

Wildlife economics and management: policy and practice.

2–21 April 1991, Canterbury/Jersey

Directors: Dr. I. Swingland, Director of the Durrell Institute of Conservation & Ecology, University of Kent & Dr. D. Waugh Training Officer of the Jersey Wild-Life Preservation Trust.

Course fee: £1760

★★★★

Advances in biotechnology (2): bioreactors in industry.

14–25 April 1991, Edinburgh.

Directors: Professor C.M. Brown, Director, International Centre for Brewing and Distilling. Dr. L.R. Weatherley, Dept. of Chemical & Process Engineering, Heriot-Watt University, Edinburgh.

Course fee: £1180

★★★★

Biosensors and their application to biotechnology, medicine and the environment.

11–21 May 1991, Newcastle-upon-Tyne.

Director: Professor A.K. Covington, Professor of Electroanalytical Chemistry, Faculty of Medicine, University of Newcastle-upon-Tyne.

Course fee: £1165

All course fees are inclusive of accommodation

120 YEARS AGO

The fabled alligator captured in the Thames some months ago has been surpassed by a hippopotamus disporting itself in the Seine. The scarcity of water has been so great in the Jardin des Plantes, that his majesty had been taken by his keepers to the river for his daily bath, securely held, as was thought, by his chain. One day, however, he snapped his chain during his gambols, to the no small dismay of the *blanchisseuses* and steam-boat passengers, one lot of whom he threatened to demolish at a mouthful. Several keepers who attempted to board him were treated to a playful ducking, but after the upsetting of a good number of small boats, he was at length captured and hauled ashore. The poor brute must have thought that the good old times of the pre-glacial epoch had returned.

Though the Russians boast, and with good reason, of the quality of their tea, a vast quantity of rubbish is sent to that country from China for consumption by the poorer classes. This is known as Brick Tea, and is frequently made up of the sweepings of the manufactories and warehouses mixed with bullock's blood and other refuse, and compressed into hard cakes or bricks; for use it has to be boiled. In some parts of India the natives use a similar kind of brick tea to make a thick kind of drink more like soup.

Tea contains an active principle called "theine" and a volatile oil, it also contains about fifteen per cent. of gluten or nutritive matter, and about twenty-five per cent. of tannin or astringent matter. The effect of theine upon the human system is to excite the brain to greater activity, but whether or not it soothes the vascular system by preventing the rapid waste of the body, is a point upon which physiologists are not quite agreed. Theine, however, if taken in excessive quantities produces tremblings, irritability, and wandering thoughts. It has been recommended that when these symptoms show themselves, cocoa should be used as a beverage for a few days.
"Tea", J. R. Jackson.
From *Nature* July 14, 1870.

100 YEARS AGO

Mr. L. W. Wiglesworth, writing from Brunswick, says:– "I am indebted to a friend for the following observation. A squirrel, in leaping from a height of 33 feet to the ground, caused itself, by means of curving its tail strongly to one side just before alighting, to swerve in its course and so avoid some hard substance upon which it would otherwise have fallen. It landed safely upon a more suitable spot. If no one has done so already, I should like to call attention to the use of the squirrel's tail as a steering and balancing organ during the animal's passages through the air."

For the first time since the establishment of the Gardens of the Zoological Society there is now to be seen there one of the ancient breed of the English wild cattle, Earl Ferrer having presented to the Society a fine young bull, which he captured in Chartley Park, Staffordshire. From Garner's "Natural History of Staffordshire" it appears that the wild ox formerly roamed over Needwood Forest. In the thirteenth century William de Farrarus caused the park of Chartley to be separated from the forest, and the turf of this extensive enclosure still remains almost in its primitive state. Here a herd of wild cattle has been preserved down to the present day, and they retain their wild characteristics, like those at Chillingham.
From *Nature* July 10, 1890.

50 YEARS AGO

While difficult to define, the sensation of 'stuffiness' is easily recognized subjectively by everyone. Since the sensation can be caused by overheating, it is essential in work on stuffiness to mak sure that the human subjects of the experiment are comfortable a regards warmth. Following the procedure of earlier investigation on human comfort, a numerical scale, the substantial linearity c which has been demonstrated statistically, was allotted to th various comments on sensations of stuffiness and freshness expressed by the subjects. The reactions of 'sessions' of about ten peopl each, tested separately, could then be averaged. By such methods has been shown that sensation of stuffiness increases, *ceteris paribu* with air temperature, according to a definite smooth curve.

An experimental gas fire has been built consisting of a blackene iron plate 14 in. × 16 in. with nine chromel alumel thermocouple embedded in it at strategic points. Its temperature can be varie over a wide range by control of the gas rate, and can be measured b means of the thermocouples. Spectrometric investigations hav shown that the fire approximates to a 'black' or 'grey' body, an confirmed the wave-lengths of maximum energy calculated fro temperature measurements.

The results so far obtained suggest that 'stuffiness' is associate with values of λ max. of about 3 μ, 4.1 μ and 4.8 μ, with regions o freshness in between; where a low temperature for 'neutral' freshness, that is, neither fresh nor stuffy, means a wave-length associated with stuffiness and vice versa. With the longer wave-lengths the quantity of radiation is smaller, the subject nearer to the fire and therefore less evenly warmed by it, and the results more erratic.
"Radiation and 'Stuffiness'", K. W. Yarnold and H. D. N. Fitzpatrick.

In his presidential address on "Wolf-Children" delivered before the Folk-Lore Society on February 21 (*Folk-Lore*, **51**, 9; 1940), Dr. J. H. Hutton deals with the cases recorded from classical antiquity down to the present time of children having been reared by animals, especially wolves. The earliest record of a wolf-child which he has discovered in northern Europe is that reported by William Dilich in 1341 as occurring in Hesse. Two Lithuanian cases of wolf-children were described by Connor in his "History of Poland", published in 1698, since when no cases have been described in Europe. Many recent cases, however, have been reported from India, mostly from the United Provinces, and also from Central India and Africa.

Wolves are not the only animals which have been said to have carried off and suckled children. In classical antiquity, Atalanta is stated to have been suckled by a bear and Cyrus by a bitch, while in recent times bear-children, jaguar- and leopard-children have been recorded in India, and lion-children and a baboon-child in Africa. It is a remarkable fact that no stories of the kind have been reported from the New World, where examples of wolf- and bear-children might have been expected from North America and jaguar- and puma-children from South America.
From *Nature* July 13, 1940.

10 YEARS AGO

Citing circumstantial evidence of the use of poison gas by Soviet troops in Afghanistan, the US Congress has taken the first step towards ending an eleven-year moratorium on the production of chemical weapons. By-passing the White House — which has nevertheless so far raised no objection — the House of Representatives last week approved the army's use of funds to renovate facilities at its Pine Bluff Arsenal in Arkansas to house the production of so-called binary chemical weapons.

Binary weapons, the latest thing in the military gas-man's catalogue, offer safe storage and use; two relatively innocuous chemical components which react to produce a military gas only after the weapon has been primed. The US Army has been working on their development since the mid-1960s.
"Chemical weapons: Congress agrees".
From *Nature* July 10, 1980.

IN NEXT WEEK'S ISSUE

Competing theories of cosmology assessed ■ Testis determining gene ■ On the energetics of running ■ Increased nitrate concentrations in Arctic snow ■ Scanning tunnelling microscopy images of DNA at atomic level ■ Ozone and hydrogen peroxide in forest air

ommentators: Charles Janeway (Yale)
olly Matzinger (NIH)

BOOK BEFORE 31 AUGUST TO SAVE $75

- Understanding at the molecular level of immune recognition has provided new insight into fundamental mechanisms of immunity and new approaches to immunopathology and therapy.
- Identification of potentially self-reactive receptors on T lymphocytes has led, through the use of transgenic mice, to an understanding of natural mechanisms of immune tolerance.
- Specific T-cell receptors may be associated with autoimmune disease and may offer a new target for therapy.
- New ways of defining immunogenic antigens have emerged from the structure of HLA, and have stimulated new approaches to the design of vaccines.
- Definition of the interleukins that invoke immunoglobulin E responses suggest new targets for the treatment of allergy.
- "Humanized" antibodies promise new approaches to tumour therapy.

Many new questions arise. Do some HLA allelés confer resistance to autoimmune disease by causing the deletion of specific T cells during the normal induction of tolerance? What part does antigen processing play in determining immune responsiveness? Can the "superantigens" that cause toxic shock help to explain how each individual's unique T-cell receptor repertoire is selected during development? How can engineered antibodies out-smart evolution in the generation of magic bullets against disease? To explore these questions and explain the most recent advances, leading researchers have been invited to speak on the basic science and its therapeutic implications, with organized discussions led by invited commentators.

We expect the conference to sell out well before opening, so urge you to make sure of your place now by returning the form below. TO SAVE $75 BOOK BEFORE 31 AUGUST

NEW HORIZONS IN IMMUNOLOGY: 15–16 November 1990

REGISTRATION FEES
Standard rate including reception
$275 before 31 Aug 1990
$350 after 31 Aug 1990
Special rate for full-time academics and government employees only
$225 before 31 Aug 1990
$300 after 31 Aug 1990

Sponsor's liability: should the conference be cancelled or postponed for any reason, the sponsor's liability is limited to the return of the registration fee. Cancellation policy: all cancellations must be received in writing. Cancellations before 30 August will be subject to $25 service charge. No refunds will be made after that date. Registrants unable to attend may send a substitute.

Please reserve ____________ places for me at Nature's conference 15–16 Nov 1990

MAKING CORTICAL CONNECTIONS

New ideas on cystic fibrosis
Targets of transcriptional activators
Artificial double helices

Biometra® presents:

TRIO THERMO BLOCK
for cyclic temperature profiles

No more …
"waiting for the last tube"

by utilizing 3 independently driven thermoblocks in just one instrument

- immediate processing of finished samples while others are still under preparation
- up to 60 samples of 0.5 mls in 3 blocks with superior block temperature uniformity
- microprocessor controlled Peltier technique for ultimate temperature accuracy
- cooling of samples possible at any stage of experiment
- rapid temperature changes for maximum saving of time
- 12 variable programmes with macro functions for complex cyclic and non-cyclic temperature profiles

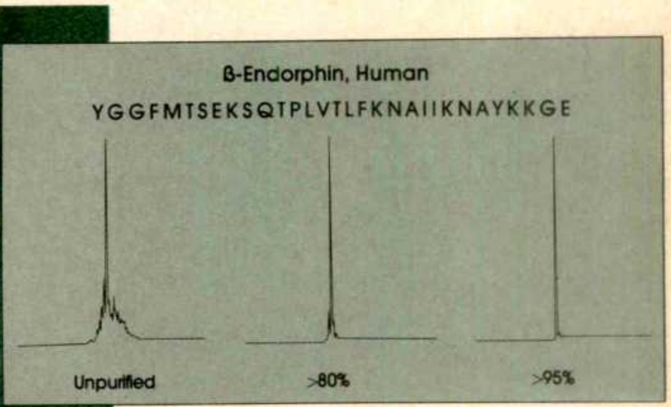
NOW Purified Peptides

MPS specializes in quality, custom peptide synthesis . . . so you don't have to!

In order to meet the differing needs of individual researchers, we are now offering three grades of peptides: unpurified, >80% purity and >95% purity. Additionally, for those using peptides to raise anti-peptide antibodies, MPS also provides a peptide carrier conjugation service. Call us with your questions or if you would like a complete price list.



COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

		Guaranteed Purity Level	
	Unpurified	>80%	>95%
Quantity	50-100 mg	30-50 mg	20-30 mg
10 mer	$400	$700	$1000
15 mer	$550	$850	$1150
20 mer	$800	$1200	$1600

CAN YOU SYNTHESIZE & PURIFY PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, purification, waste disposal, laboratory space, downtime and, of course, the initial cost of the synthesizer.

Multiple Peptide Systems

10955 John Jay Hopkins Drive, San Diego, CA 92121 USA

Telephone (619) 455-3710
FAX (619) 455-3713
Outside California (800) 338-4965

MPS also provides a unique HF Cleavage Apparatus and a complete HF Cleavage Service.

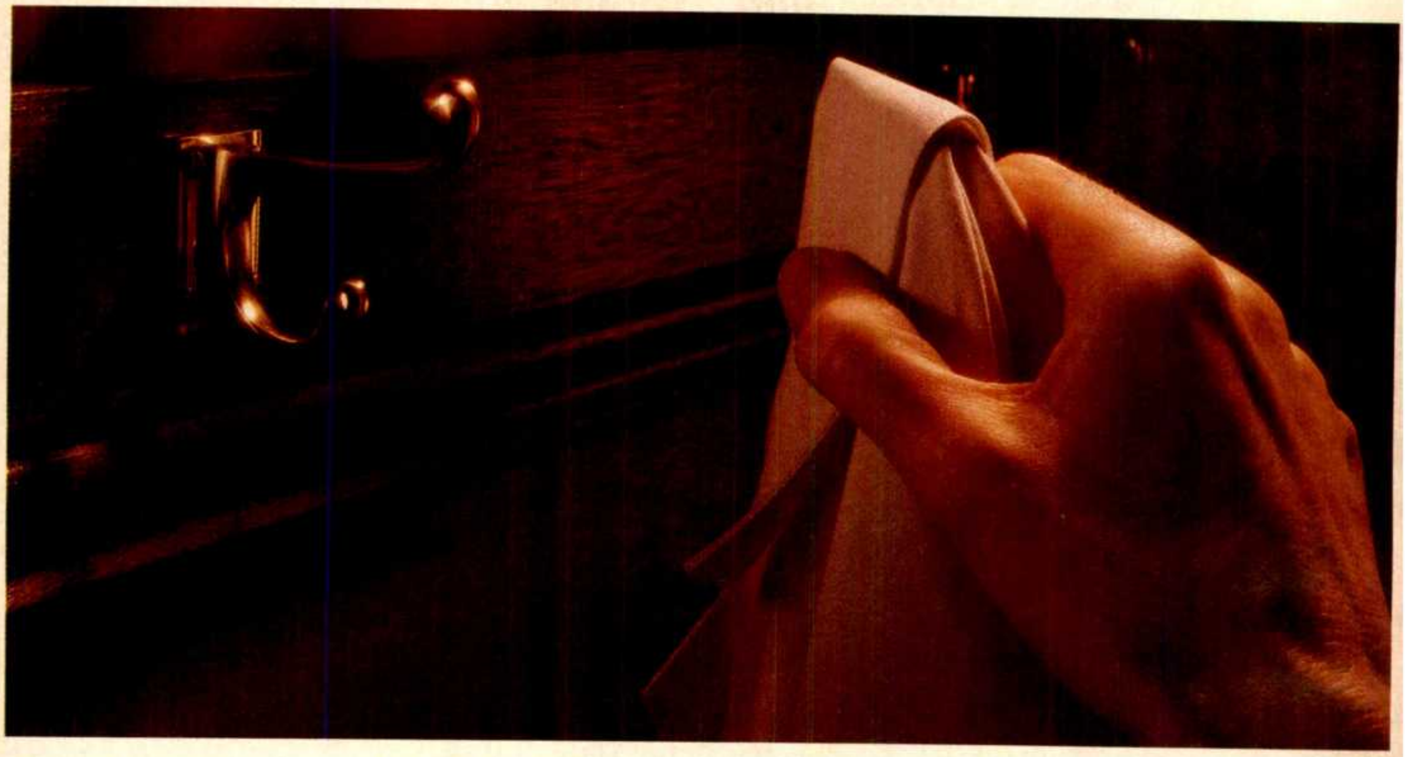
Recombinant proteins you can hang your reputation on



In scientific endeavours, exploring the unknowns in research demands precise tools and well-defined materials to ensure consistent, reproducible results… After all, your results are your reputation.

The HIV Recombinants from Pharmacia Genetic Engineering Inc. – Phage – have been designed to meet the strict standards your research demands. We are proud to offer these "perfect constructs" (there are no extra amino acids) generated by the Phage recombinant technology, and purified to a level which you expect from a company with Pharmacia in its name.

HIV p24 CORE POLYPEPTIDE

Aqueous soluble polypeptide. Purity above 99%. Strongly antigenic and immunogenic. It contains no N-terminal methionine, but it does contain the 231 amino acids of the authentic p24 sequence. Wide applications in HIV related research. Dispensed in 100µg/vial.

HIV-1 p24-ENVELOPE FUSION

This unique polypeptide combines into one molecule the entire p24 sequence and inserted into it a highly conserved region taken from the gp41 portion of the HIV-1 env gene product. No evidence of interference between p24 and env- derived epitopes. And no N-terminal methionine. Excellent properties as scavenger of antibodies following HIV infection. (Has been shown to detect positive samples previously falsely scored as negative in other tests.) Purity exceeds 97%. Dispensed in 100µg/vial.

HIV-2 p24-ENVELOPE FUSION

This polypeptide is analogous to its HIV-1 counterpart (left) except that a highly conserved sequence taken from the gp36 transmembrane portion of the HIV-2 env gene product has been inserted into the gene of p24 and then brought to expression. The purity is greater than 97%. Highly useful in several research applications including the detection of antibodies in sera from individuals infected by HIV-2.

p17 CORE POLYPEPTIDE

The p17 polypeptide from HIV-1 constitutes the N-terminal portion of the gag-derived precursor molecule encoded by the virus. Useful when comparing p17 and p24 responses. Made as 97%+ pure material and lacks N-terminal methionine as well as the myristoyl group.

If any of these proteins can help you make your mark on the world, contact Phage now. There is more in the pipeline, and we would be happy to talk about your needs and how we may help you fill them! After all, reputation is built by excellence and thoroughness in service – that is where we put our priority.

Write, fax or phone for further information and to place orders. Phone: **1-619 455-0011**. Fax: **1-619 455-0044.**

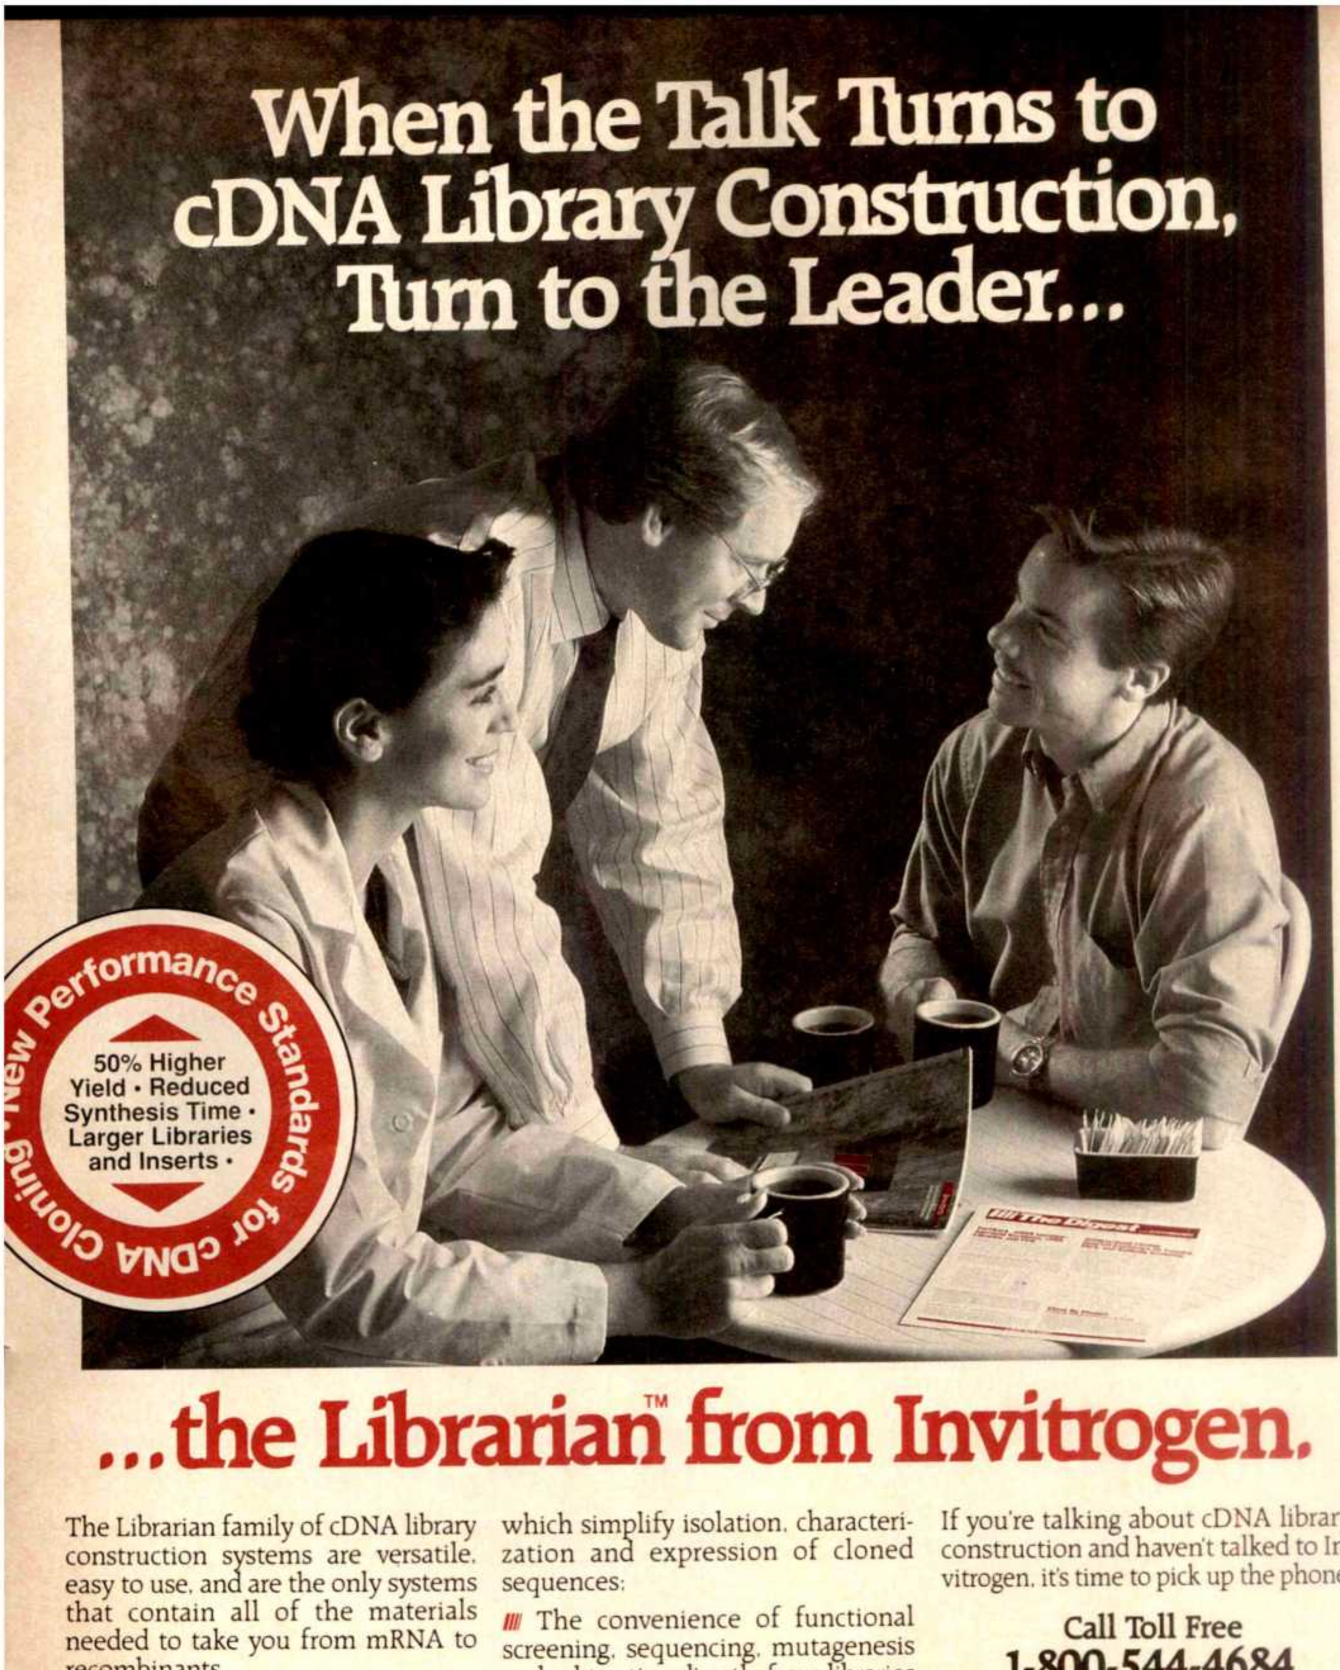
When the Talk Turns to cDNA Library Construction, Turn to the Leader...



New Performance Standards for cDNA Cloning
50% Higher Yield • Reduced Synthesis Time • Larger Libraries and Inserts •
The Digest

...the Librarian™ from Invitrogen.

The Librarian family of cDNA library construction systems are versatile, easy to use, and are the only systems that contain all of the materials needed to take you from mRNA to recombinants.

The Librarians offer:

- Modular design that includes prepared vector, E. coli and all enzymes and reagents; quality controlled as a complete system for optimum efficiency;
- Your choice of mammalian, yeast, or prokaryotic expression vectors which simplify isolation, characterization and expression of cloned sequences;
- The convenience of functional screening, sequencing, mutagenesis and subtraction directly from libraries constructed in the Librarians phagemid vectors;
- A highly efficient method for size selecting cDNA generated by random or oligo dT priming;
- Technical service personnel with the experience to provide reliable information and assistance.

If you're talking about cDNA library construction and haven't talked to Invitrogen, it's time to pick up the phone.

Cytokine and growth factor assays

Amersham-the first choice

Amersham has now extended its range of cytokine assays to four, with the introduction of:

Interleukin-6 [^{125}I] radioimmunoassay

Sensitivity: 0.1 fmol/tube (2.2pg/tube)
Working range: 0.25-16 fmol/tube
(5.5-352pg/tube)
Ordering code: RPA 537

Related products	**Ordering code**
Interleukin-1α [^{125}I] RIA	RPA 528
Interleukin-1β [^{125}I] RIA*	RPA 533
Interleukin-2 [^{125}I] RIA*	RPA 531
Tumour necrosis factor α [^{125}I] RIA*	RPA 532
Fibroblast growth factor (basic) [^{125}I] RIA*	RPA 534
Platelet-derived growth factor [^{125}I] RIA*	RPA 536

All of Amersham's cytokine and growth factor assays offer the advantages of:

- Highly specific antiserum
- Sample validation
- Overnight results
- Amerlex-M magnetic separation (except PDGF assay)

*Assay systems developed jointly with Amgen Biologicals,Thousand Oaks, CA, USA.

Vol. 346 Issue no. 6282

◀ The cover shows projection neurons in an organotypic culture with the fluorescent dye DiI from a cocultured target area of the visual cortex. Cortical projections established in culture are remarkably similar to those *in vivo*. See page 359.

THIS WEEK . . . THIS WEEK . . . THIS WEEK . . .

CF defect modelled

The product of the cystic fibrosis gene is thought to be a transmembrane transporter protein with an ATP-binding domain on its cytoplasmic face. Predictions of the secondary and tertiary structures of this domain reveal a similarity to that of adenylate kinase, but the predicted structure suggests that genetic defects in a hydrophobic loop, rather than in the ATP-binding site, cause cystic fibrosis, page 362. A number of new cystic fibrosis mutations include a cluster of substitutions at residues conserved among ATP-binding transport proteins, further strengthening the case that the gene product really is such a transport protein, page 366. See News and Views, page 312.

Gene activation

Cloning of the human transcriptional activation factor TFIID reveals a remarkable evolutionary conservation of the TFIID core, and a completely distinct N terminus with structural motifs analagous to those of other regulatory factors and co-factors, page 387. On page 390, Gasch *et al.* show that the plant *Arabidopsis thaliana* contains two distinct genes for the TFIID factor, the first direct evidence for the presence of multiple TATA binding factors in a eukaryote. Recent research on the mechanisms of eukaryotic transcriptional activators using cloned TFIID has led to apparently contradictory results. On page 329 Ptashne and Gann suggest how the conflicting conclusions may be reconciled.

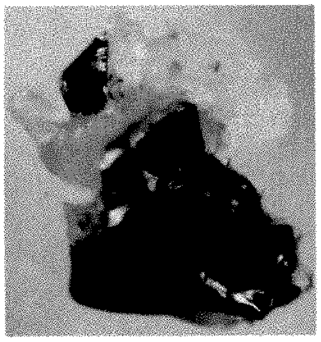
Chemistry imitates life

DNHs, a new type of artificial compound combining a double-helical structure with selective interaction features analogous to those of nucleic acid bases, may provide structural and functional models for the study and mimicry of the functions of DNA. Pages 339 and 314.

Guppy love

A long-term study of guppies living in environments with different predators bears out the prediction that reduced adult survival selects for earlier maturation and increased reproductive effort. Pages 357 and 313.

Uncommon carbide



Crystals of silicon carbide, one of the rarest minerals in nature, from a diamond-containing kimberlite. Hexagonal (deep blue) and cubic (milky-coloured) polymorphs can be seen. Actual height of specimen 0.7mm. See page 352.

Kidney disease

The onset of experimentally induced disease in the animal model of acute proliferative glomerulonephritis — an inflammatory disease of the kidneys — is causally related to increased production of transforming growth factor beta, suggesting a possible new therapy for the human disease, page 371.

Light programme

The synthesis of polymer gels that undergo a reversible, discontinuous volume phase transition on exposure to light (page 345) holds out the prospect of producing energy-conversion devices for the direct utilization of energy derived from sunlight. Potential applications might include artificial muscles, switches and memories.

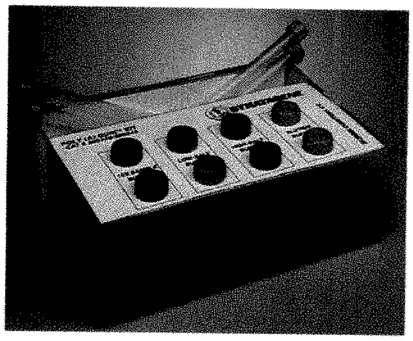
AND FAST.

Stratagene's Poly (A) Quik™ kit purifies polyA$^+$ mRNA from total RNA in just minutes.

The ability to isolate messenger RNA molecules via polyA$^+$ selection over Oligo (dT) cellulose has greatly facilitated the study of eukaryotic genes (1). Until recently, the protocol for Oligo (dT) cellulose chromatography involved the use of standard drip columns with a typical yield of only 1% mRNA (2).

Oligo (dT) spin columns were introduced to replace drip columns, reducing the total time required to 1 hour. Stratagene has now reduced that time to 15 minutes with the Poly (A) Quik™ push column.

Stratagene's new Poly (A) Quik™ kit allows rapid chromatography without the need for column preparation or centrifugation equipment. From start to finish, poly A$^+$ RNA can be isolated from total eukaryotic RNA in less than 15 minutes with poly A$^+$ yields equivalent to 2 to 3% of total RNA (3). Poly (A) Quik push columns and all of the necessary buffers are included within the kit.



For more info call Technical Services at 1-800-548-1113.

Total RNA was extracted from transgenic and non-transgenic mouse liver using the Stratagene RNA isolation kit. One mg of transgenic total RNA was passed twice over a Poly (A) Quik™ push column, and the poly A$^+$ fraction was purified. Samples were electrophoresed on a VAGE™ vertical formaldehyde agarose gel, vacuum blotted, UV cross linked, and hybridized to a DNA probe to detect the presence of the transgene.

A: 5 μg non-transgenic mouse liver total RNA.
B: 5 μg transgenic mouse liver total RNA.
C, D & E: 500, 175 and 75 ng of poly A$^+$ enriched RNA from the Poly (A) Quik™ push column.

Comparing the signal intensity in lane B with lanes C-E, shows that the Poly (A) Quik™ push column enrich RNA sample for poly A$^+$ species over 50 fold.

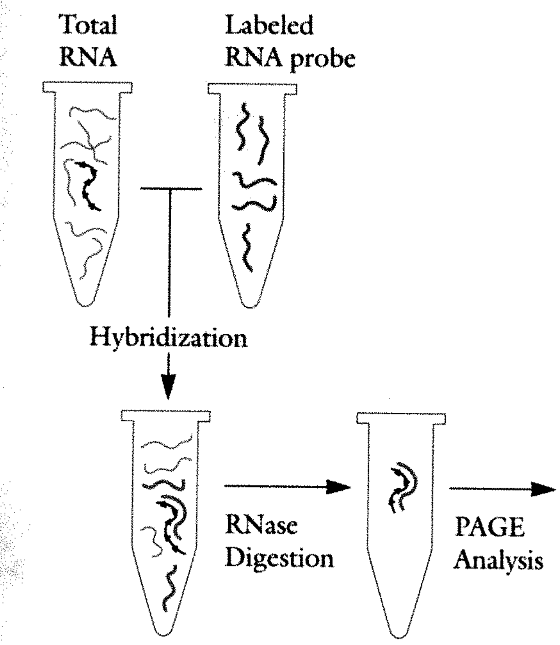
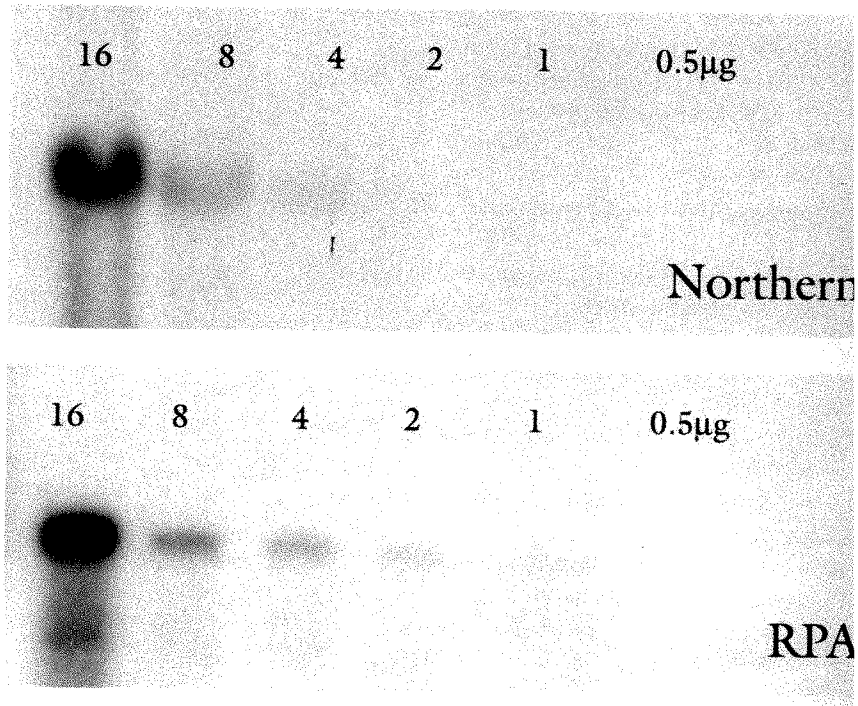
10 Times More Sensitive Than a Northern

New RPA™ Kit

Ambion announces the
Ribonuclease Protection Assay Kit





Note: The RPA was exposed 1/10th as long as the Northern.

The indicated amounts of total mouse liver RNA were analyzed by Northern blotting and Ambion's RPA Kit using a ^{32}P labeled RNA probe complementary to a 250 nucleotide region of the mouse β-actin transcript. The Northern blot was exposed for 64 hours and the Ribonuclease Protection Assay gel for 6.4 hours, both with an intensifying screen.

The Ribonuclease Protection Assay is an extremely sensitive technique for detecting and quantitating RNA. It is at least 1 times more sensitive than Northern blotting. Ambion's RPA k contains pretested reagents for 120 reactions, positive controls and detailed protocols for both new and experienced users that allow you to use this powerful technique.

- Detection and Quantitation of RNA
- Tolerant of Partially Degraded RNA
- Detect Low Abundance Transcripts without Poly A Selectio
- Mapping Initiation / Termination Sites
- Mutation Mismatch Analysis

STABILITY UNDER FIRE.

A NEW GENERATION OF HEAT STABLE VENT™ DNA POLYMERASES

STABILITY AT 100° C AND PROOF READING ACTIVITY

New England Biolabs, Inc. announces the first in a new line of DNA polymerases that remain active at 100° C. Vent™ DNA polymerase retains activity for over two hours at 100° C. while Taq DNA polymerase loses practically all activity in 10 minutes. This increased thermal stability allows experimental approaches never before possible.

In fidelity experiments, the proven 3′ to 5′ proof reading activity of New England Biolabs' Vent™ DNA polymerase results in fewer base-insertion errors than Taq DNA polymerase.

NATURE VOL 346 nature 26 JULY 1990

The post-Marx dearth of capital

The collapse of communism, the antithesis of capitalism, in Eastern Europe, and its economic failure in the Soviet Union, has brought to light a paradoxical circumstance — the world is dangerously short of capital.

KARL Marx, in retrospect, had a very simple view of life. People would work for the benefit of their communities, benefitting personally, like all others, to the extent the community saw fit. In stalinist times, marxism was an excellent recipe for what would elsewhere have been called capital formation. It was simply necessary to adjust the ratio of those employed to build factories and on other long-term projects to those employed to provide the community as a whole with the necessities of life. The growth of heavy industry in the Soviet Union during the 1930s was a remarkable proof of the efficacy of the process. One of the reasons why communism has come unstuck is that too little was left over to satisfy the legitimate aspirations of the people for a better life. (The accompanying lack of liberty is something else again.) It is a savage irony that most of this past capital investment is inappropriate to modern needs: it has been wasted.

So Eastern Europe and the Soviet Union are on the look-out for more capital, but at the least auspicious time. Most other places are also crying out for the same stuff. Where to find it, and how to recognize it when you do? Capital is nothing but money, and thus indistinguishable from what people use to buy train tickets or dishwashers. The difference is that capital is the money left over after people have spent what they wish to spend on their immediate needs and have paid the interest on their debts. At the personal level, capital is a person's savings. At the national level, the maximum indigenous rate of capital formation is the aggregate of these savings less the net cost of keeping the government in business. People, businesses or governments needing more capital than they have saved must borrow it from the banks and the other agencies of what is now an international market in capital.

Lip reading

The obvious difficulty, for Eastern Europe and the Soviet Union, is that the natural sources of capital are in dire need of the stuff themselves. In the United States, President George Bush has had to go back on his memorable election promise that there would be no new taxes (devices for enforcing savings) in the hope of an agreement with the Congress that the annual budget deficit will be reduced by two-thirds, or by a cool $100,000 million. In Britain, where the personal savings ratio has also fallen dramatically in the past decade, the hapless Minister of Transport, fresh from ruling that the country cannot afford a high-speed rail link to the Channel Tunnel or even a new subway line across London, let slip at the weekend that it cannot afford a new aircraft runway in South-East England either.

But not everybody is strapped for capital. In several countries, Japan and West Germany particularly, both the personal and the corporate sectors are saving hard, while corporate sectors elsewhere have money left over after paying dividends to their shareholders. Where does that finish up? During the past decade, it has been fashionable to invest in the United States, sometimes by buying companies outright (to the frequent chagrin of the locals), sometimes by lending directly to the US government. The reunification of Germany will seriously disturb that habit. The Bonn government, for example, estimates that reunification will cost it DM80,000 million in 1991, most of which will be borrowed from the banks. German companies will invest several times as much in the East. What will be left over for other people?

That is where the crunch comes. When capital is scarce, its price increases, which is why interest rates are likely to remain high for a long time. Outside the umbrella of united Germany, Poland, Czechoslovakia and Hungary will find themselves paying through the nose for private investment — and may consider themselves to have been exploited as a consequence. The imaginative idea of a European investment bank, due soon to be a reality, should blunt the edge of that discontent, but not by much. There will be two losers — the United States, where the economy seems nicely poised between boom and recession, and the poor countries of the world, which will be now more than ever dependent on government-backed assistance, either bilateral or through institutions such as the World Bank. Either way, it is a dangerous prospect for the rest of us. □

Genome goes cool

The human genome project deserves a better hearing from the US Congress than it is likely to be given.

THERE is no good reason why the US House of Representatives should have soured in its view of the Human Genome Project. It would be different if the House were zealously cutting every possible budget item so as to bring the federal deficit under control, but that is plainly not the case. The Senate may be able to insist that the project should not be made to rub along, in the year beginning on 1 October, on roughly half of what it needs from the National Institutes of Health, but it is not well placed to make that point (see page 309). The excuse that the earmarking of research funds for a particular project undermines the primacy of the principal investigator sounds like a deliberate misunderstanding; that the project would consist of a great deal of production-line research work has been made clear from the start.

The essence of the case for the genome project is that the sequence of the human genome will not be compiled by accident. Despite the speed with which particular human genes are being identified and their nucleotide sequences established, the indefinite continuation of that process will never yield the nucleotide sequences of the apparently boring bits of the genome that lie between identified genes, whose evolutionary significance may nevertheless be great. And there is no prospect that even the present rate at which human genes are being identified will make the human genome the analytical tool it might be — a databank of which it is possible to ask interesting questions. Unless the compilation of that databank is commissioned, it will never exist.

That is the case against the position taken by the House Appropriations Committee, but it should be acknowledged that the genome project's own posture is not without its inherent problems. It is caught in a dilemma created by its own existence. The prospect of a deliberate effort to sequence the human genome has stimulated a plethora of new techniques, further complicating the development of a coherent strategy. Sensibly enough, the project plans to cut its teeth on the sequencing of a smaller genome, while constructing a physical map of the human genome. The plan to use NIH money to commission some centres now will give the project the luxury of choice at a later stage, when the responsibility for the long haul will have to be shouldered by a subset of them. Congress's long experience with military projects should be a warning against parsimony at this early stage. But that is a less clear message than those to which congressmen are used.

The military analogy can be taken at least one step further. Making a telling case to the US Congress is a matter of giving the impression that the objective is nicely crystallized without inhibiting the freedom to change course radically at a later stage. Generals pleading for funds for exotic new weapons systems have learned to give the Congress the impression of always knowing exactly what they want; if they later change their minds, they usually manage to get away with it. One consequence of what is called the peace dividend is that there will be experienced Pentagon negotiators out of work. It might suit the genome project's book to hire one or two of these experienced operators to get the appropriations bill through Congress. ☐

Television violence

Evidence that television breeds violence remains as elusive as ever.

WHETHER or not television has the inherent power to incite violence in its consumers, the square-eyed hordes seem to have more personal and cultural 'fortifications' than is usually supposed. The annual research review of the Broadcasting Standards Council, published last week, leapfrogs the debate in Britain over whether the content of television should be regulated, calling instead for a general and dispassionate recognition of the complexity of the issue and, crucially, of the viewer.

The report, the council's first since it was set up in 1988 on an ominous 'pre-statutory' basis, takes a refreshing approach to what has become a rather turgid issue. Instead of trying to account for the role of television in the violent behaviour of violent criminals, the council's researchers, led by Dr David Docherty of the London School of Economics, has asked how television may affect the attitude of the viewing public towards violence itself.

For their main survey, the researchers asked just over 1,000 British viewers how they felt about violence in Britain today — a survey which, as well as providing a useful gauge of public sentiment, allowed the researchers to test for correlations between people's television consumption and their overall attitude towards violence. For instance, do heavy television consumers feel differently about 'legitimate' violence, such as capital punishment and armed police action, than their more abstemious counterparts, and are they, in general, less secure about their own safety?

For the most part, the research shows no significant differences between the heavy viewers and the light on such questions. In fact, the issue that provokes the clearest discrepancy between the two groups — the arming of police in various confrontational situations — shows heavy television viewers to be cooler-blooded in every instance than their library-going and apple-bobbing compatriates. The report concludes that there is a qualitative sifting, on the part of the viewer, of violent images into different categories of palatability. Docherty suggests that it is the extent of the viewer's involvement in the fiction that is the determining factor in these classifications. Television violence that somehow involves the viewer — whether by eliciting an intellectual response or simply by reflecting life in Britain — is far more likely to upset than that which makes fewer claims to realism. In short, the report holds that the context of fictional violence is at least as important as its substance when it comes to earning the label "unacceptable"; and, whether or not television has the power to incite people to violence, viewers are more actively discerning than some proposed legislation gives them credit for. The research does not provide justification for the restrictive regulatory regime that some would like. ☐

First UK trial of AIDS vaccine approved

- First step is cautious but safe
- Twenty volunteers to test prototype

London

THE first British trial of a prototype AIDS vaccine was given the go-ahead by the UK's Medical Research Council (MRC) last week.

The phase I trial, which will be carried out under the aegis of the MRC's AIDS-related research programme, is to begin in September at London's Hammersmith Hospital, where a candidate vaccine known as p24-VLP will be administered to 20 healthy seronegative volunteers. Their immune response to the vaccine will be monitored for up to a year before a decision about further trials is made.

Developed by Oxford-based British Biotechnology Limited, p24-VLP consists of a fragment of an HIV protein known as p24 presented on the surface of a newly-emergent vaccine carrier known as a virus-like particle (VLP). Although not infectious, VLPs possess some of the basic elements of retroviruses, and can be prepared easily in a pure state from genetically engineered yeast cells. Researchers at BBL have shown that VLPs are able to carry proteins that induce HIV-specific immune responses in animals.

News of the trials comes almost three years after the start of the first clinical trial of a prototype AIDS vaccine in the United States. Jane Cope, who is orchestrating the MRC's AIDS vaccine strategy, says that the MRC "didn't want to rush into human studies" without first laying the foundations of a well organized trial system.

But aside from caution, there may be other reasons why the announcement of the first UK trial has been slow in coming. One factor, according to Alan Kingsman, director of research at British Biotechnology Limited, is the dearth of small biotechnology companies in Britain: "The big companies haven't been keen to take it [vaccine development] on", he says. Jonathon Weber of the Hammersmith Hospital, who will be in charge of the clinical trials, notes that most US trials have focused simply on the response of the human immune system to large quantities of crude HIV proteins or peptides. The British trial, however, has a different emphasis: to test the feasibility of using VLPs as novel carriers for 'immunogenic' HIV peptides in humans.

Caution is also evident in the choice of p24 as the vaccine's immunogenic component. Most vaccines tested so far have used the HIV envelope proteins gp160 and gp120, on the grounds that these proteins are exposed on the surface of the virus and so should be strongly immunogenic. In the past, however, questions have been raised about the safety of envelope-derived vaccines, which some researchers have suggested could act to suppress the immune system. No such concern has been expressed over p24, largely because, being a core protein of HIV, it does not participate directly in the virus's interaction with T cells.

Kingsman and Weber agree that p24 alone is unlikely to provide protective immunity against HIV. They view the trial as the first step towards developing a vaccine in which VLPs carry a 'cocktail' of HIV immunogenic protein fragments. The p24 protein is known to stimulate helper T cells in animals and so might play a part in creating protective immunity.

Although trial voluteers will produce antibodies to HIV, the MRC has given assurances that no one will be mistakenly thought to have HIV infection, and so volunteers should have no difficulty obtaining life assurance or mortgages on medical grounds.

The researchers were coy about how they intend to recruit volunteers, but it is unlikely that they will need to call on members of the public. **David Concar**

COLD FUSION

Second round

Washington

FIFTEEN months after the appearance of their first paper announcing the discovery of "cold fusion", Martin Fleischmann and Stanley Pons have published a second paper, 56 pages long, in which they give a full account of the electrochemistry and calorimetry behind their claim that electrolysis of heavy water with palladium cathodes generates more heat than conventional chemistry and physics can explain. The paper, written by Fleischmann, Pons, M.W. Anderson, L.J. Li and M. Hawkins, all of the Department of Chemistry at the University of Utah, appeared in the 25 July 1990 issue of the *Journal of Electroanalytic Chemistry and Interfacial Electrochemistry*, the same journal in which a short paper by Fleischmann, Pons and Hawkins appeared on 10 April 1989.

According to an announcement by Elsevier Sequoia, the journal's publisher, the new paper addresses only questions of electrochemistry, and contains no information on the emission of nuclear particles or radiations which would be expected if "cold fusion" reactions are indeed occurring. The accuracy of the calorimetric results is demonstrated, Elsevier says, by comparisons of palladium–heavy water cells with control experiments using palladium electrodes in light water and platinum electrodes in heavy water. In the absence of direct evidence for nuclear processes in the cells, the implication that fusion is responsible for the excess heat is drawn "by elimination". David Lindley

BRAIN RESEARCH

Heading for the nineties

Washington

US neuroscientists' attempts to turn a Congressional resolution designating the 1990s the 'Decade of the Brain' into a financial reality gained a little help last week when US president George Bush signed a proclamation calling on the decade to be observed with "appropriate programmes", and the First Lady, Barbara Bush, opened a two-day meeting intended to publicize the start of the decade.

Both the National Institute of Mental Health (NIMH) and the National Institute of Neurological Disorders and Stroke (NINDS), the two institutes of the US Department of Health and Human Services most likely to benefit from increased efforts in neuroscience, have already released plans laying out what could be achieved in the decade.

The report from NINDS, released last month, also reveals what the decade might cost — for NINDS alone an initial increase of $221 million above the administration's $500 million budget request, followed by a further rise of similar size two years from now.

Funding requests on this scale need a compelling argument if they are to make it through Congress. At last week's 'Decade of the Brain' meeting at the National Academy of Sciences, the logic came in two parts. At the meeting were a selection of the finest neuroscientists working in the United States, speaking in a programme that ran from work on ion channels to neural-network computing. These scientists delivered the first part of the message — that neuroscience is now a mature discipline in the sense that it contains areas in which it is fairly evident what needs to be done and, broadly speaking, how to do it. What that means is that Congress and president can be sure that increased investment will translate directly into increased results.

Areas where the prospects for rapid progress are good were listed by NIMH in a document given out at the meeting: they include the identification and cloning of the genes responsible for schizophrenia, manic-depressive illness, Alzheimer's disease and other mental illnesses; the detailed mapping of where various neurotransmitters and receptors act within the brain; the use of computer-analysed brain activity measurements in improved diagnosis of brain disorders, and use of models of receptor structure to design and synthesize drugs that could help treat conditions, such as schizophrenia, that are thought to be to due to defects in neurotransmission.

The second part of the logic, presented most graphically by Lewis Judd, director of the National Institute of Mental Health is that mental illnesses are a gigantic burden for the health-care system. Judd points out that some 15–20 per cent of people are affected by some form of mental illness each year. The Congressional proclamation estimates that in the United States, the "treatment, rehabilitation and related costs of disorders and disabilities that affect the brain represents a total economic burden of $305,000 million annually". Investment in basic research to produce more effective forms of treatment thus has the potential for generating a large return.

"If you combine the costs of 50 million people a year suffering from mental disorders with a science that is growing exponentially then you have a potentially convincing argument that we're hoping will carry the day, and that funding will flow from it", says Judd. He and his fellow institute directors are not themselves permitted to lobby for increased funds; the job, he says, will have to be performed by the many patient groups (the Cerebral Palsy Foundation, the Epilepsy Foundation and so on) as well as the various professional and scientific societies. A first move of this kind was announced at the conference by David Mahoney, a director of the Dana–Farber Foundation. The foundation is to set up an institute to lobby for support for the decade, and a $25,000-a-year prize to be offered each year of the decade to an outstanding neuroscientist.

Are president and Congress going to be persuaded to support the decade? The House of Representatives has already given mention of the Decade of the Brain as an "area of special concern" in its 1991 appropriations bill for the Department of Health and Human Services, but there will be very little new money available this year. A panel discussion at the conference which included Allan Bromley, White House Science Advisor, James Mason, Assistant Secretary for Health, and Frederick Goodwin, administrator of the Alcohol, Drug Abuse and Mental Health Administration, raised few hopes that riches were about to be showered on neuroscientists. Although steps are being taken to set up a coordinating committee within the White House, most talk at the conference was of the gloomy prospects presented by the growing federal budget deficit.

The next public event in the Decade of the Brain will be the start of a Library of Congress lecture series sponsored by the National Institute of Mental Health. The lectures will continue throughout the decade, with clusters of six lectures each autumn and spring. The first lecture, appropriately enough, will focus on the cost to the United States of brain-related disorders. **Alun Anderson**

DRIFT-NET FISHING

Pyrrhic victory in South Pacific

Sydney & Tokyo

Under pressure from Australia and other South Pacific nations Japan announced last week in Canberra that it will suspend drift-net fishing in the South Pacific a year earlier than required by a United Nations resolution. But the decision will have little overall effect on Japan's drift-net operations, which are based largely in the North Pacific.

Drift-net fishing, which employs sets of nets up to 60 km in total length to catch tuna and squid, has been condemned because it kills other marine life indiscriminately, in particular turtles, seabirds and dolphins. Last year the United Nations adopted a resolution, endorsed by Japan, that bans the technique in the South Pacific from 1 July 1991 and worldwide a year later, unless it is deployed using proven management techniques.

Japan's suspension will come into effect in October, the beginning of this year's season. But, as pointed out by Peter Gill of Greenpeace, "Japan has withdrawn less than thirty boats from the [South Pacific] region while they maintain over one thousand boats in the North Pacific". The South Pacific decision is "chicken feed" compared with the North, Gill says, and he doubts that the UN resolution will bring about a worldwide ban by 1992.

Tania Ewing & David Swinbanks

Wildlife response to the nets

Washington

The US National Marine Fisheries Service (NMFS) finally agreed earlier this month to release some of the data they have collected on the impact of drift-net fishing on marine life after a meeting between Congresswoman Jolene Unsoeld (Democrat — Olympia) and the director of NMFS. Unsoeld has been campaigning for a ban on the technique. The data come from a survey conducted last year by US, Canadian and Japanese observers on board some of the 470 licenced Japanese drift-net boats that catch squid in the North Pacific during the summer months.

Observers looked at a total of 1,402 'sets' of the net — about one fiftieth of the total — in each case examining about three-quarters of the catch. They found that the nets had caught 208 fur seals, 914 dolphins, 22 turtles, 539 albatrosses, 8,536 shearwaters, 25 puffins (an endangered group) and 17 storm petrels. NMFS officials are not yet ready to say what impact this level of mortality might have on the total population of North Pacific sea mammals, turtles and birds. A more detailed survey is being carried out this year with three times as many observers aboard the fishing boats.

UK ASTRONOMY

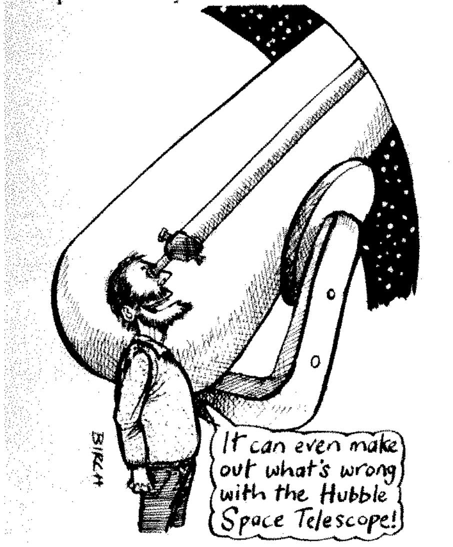
Spanish to step in?

London

THE UK Science and Engineering Research Council (SERC) last week failed to decide whether to collaborate with Spain or with the United States in a project to build what will be the most powerful optical-infrared telescope in the Northern Hemisphere.

But SERC's indecision may now tip the balance in favour of the Spanish collaboration, and is a problem for US astronomers, who need to start their project quickly.

The US National Optical Astronomy Observatories (NOAO) plan to build two 8-metre optical-infrared telescopes: one for the Northern Hemisphere at Mauna Kea, in Hawaii, and one for the Southern Hemisphere at Cerro Pachon in Chile. The National Science Foundation (NSF) can provide only half of the estimated cost of about $170 million, so US astronomers have been seeking foreign collaborators in Britain and Canada.



It can even make out what's wrong with the Hubble Space Telescope!
BIRCH

But Britain has been torn between the US collaboration and a plan to build a Northern Hemisphere 8-metre telescope in collaboration with Spain at La Palma in the Canary Islands. Here, Britain would take the lead in the instrument's construction, basing its design on the smaller William Herschel telescope, also at La Palma.

Britain's main interest is in observing northern skies. A collaboration with Spain would give more observing hours in the Northern Hemisphere, probably at a slightly lower cost, but this must be offset against the better conditions for infrared observation in Hawaii. Both projects aim to have their telescopes ready for use by the late 1990s.

The Spanish collaboration would also allow British astronomers observing time in the Southern Hemisphere. Harry van der Laan, director general of the European Southern Observatory (ESO), says that UK and Spanish astronomers will be able to use ESO's Very Large Telescope (VLT), due to start observation in 2000, provided the arrangement is reciprocal and an adequate system of peer review for one another's projects is worked out. Neither Britain nor Spain currently participates in ESO. The VLT will be a revolutionary instrument, comprising four 8-metre telescopes that can be used independently, or in unison as the equivalent of a 16-metre telescope.

SERC, which has about £20 million to invest, has now deferred its decision until December, after the financial and contractual elements of each project have been scrutinized further. The trend towards closer relations between the United Kingdom and other European countries, both in science and economically, may influence the decision. European collaboration is increasingly seen as being essential to maintain competitiveness with the United States and Japan in 'big science' projects such as space science and particle physics. Moves towards stabilizing exchange rates between European Communities countries may also favour the Spanish option. In 1987, SERC's finances were badly shaken when the UK subscription to CERN, the European particle physics centre, increased as a result of the falling value of the pound.

US astronomers now find themselves in a difficult position. Sidney Wolff, director of NOAO, says that the US project has to get started as soon as NSF money becomes available, to avoid cost overruns. Important decisions on optical design and staff appointments must be made before December, she says. By the time SERC reconsiders, the potential UK input into the NOAO project will have diminished, making it a less attractive proposition for the United Kingdom. In the meantime, British astronomers will continue to refine the design of the La Palma telescope. The delay should be less of a problem for the Spanish, who have yet to finalize their own financial arrangements.

The British indecision may also undermine Canadian support for the NOAO collaboration, although Wolff is optimistic that this will not be the case. She says that NOAO may consider other international partners, while SERC makes up its mind.

Peter Aldhous

EUROPEAN SCIENCE

UK science is sold short

London

THE Treasury's system for handling UK contributions to the European Communities (EC)'s Framework research and development programme compounds the under-funding of British science, according to a report from the House of Lords EC committee, published this week.

Under EC law, member states' contributions cannot be met in full simply by diverting money from domestic spending: there must be some 'additionality' to the EC budget. But the Treasury allows only 30–35 per cent of the UK contribution to Framework as truly additional spending, which the Lords committee says "is clearly far too low". British scientists are successful in winning EC grants, recouping the UK contribution. But Treasury policy means that for every pound of EC research money gained in one year, up to 70 pence is clawed back from the following year's domestic spending on research, by a secretive process called 'attribution' against government departments' budgets.

Attribution has worried the UK research councils, who fear their funds from the Department of Education and Science may diminish as EC spending on basic scientific increases (see *Nature* **345**, 376; 31 May 1990). The report charges that the Treasury has ignored the relatively small UK input in shaping EC research policy, as one member state amongst twelve. Many projects funded by the EC do not coincide with UK priorities.

As EC research spending increases, and attribution eats into the domestic budget, "the [UK] science community's ability to set priorities for projects could steadily diminish", the committee warns.

The report says that the Treasury must be more open about the attribution process and suggests that monitoring by Parliament is needed. The Treasury should also study how other EC states manage their contributions — Treasury officials were unable to explain the arrangements made elsewhere in the EC when asked to do so by Lord Shepherd, chairman of the committee.

The committee's inquiry into EC research and development was prompted by the European Commission's proposal for a new Framework programme, to run from 1990 to 1994, overlapping with the existing programme which finishes in 1992. The peers are satisfied with the new programme's budget, and the balance of funds between different areas of research. But the report says that the Commission needs to take more account of the views of the scientific community in individual member states. This could be achieved by appointing representatives from bodies such as the UK research councils to the EC committees that advise the Commission on science and technology.

EPIDEMIOLOGY

Valuable cancer registry

Munich

GERMAN reunification may bring an unexpected boon to the science of epidemiology in West Germany. Unlike West Germany, where strict laws to protect privacy have prevented the accumulation of national records on the incidence of cancer, East Germany has detailed records of all cancer cases since 1953.

West German doctors attending the 'first German medical congress' last month in Dresden spoke out for maintaining the East German registry and for trying to establish more cancer registries on a regional basis in West Germany. Georg Dhom, a pathologist in Homburg/Saar, said that a senior health ministry official had indicated at a meeting last month that the federal government would consider establishing a 'national framework law' to allow the collection of data from cancer patients. Dhom is a member of a health ministry working group concerned with cancer epidemiology.

But as health policy is decided in West Germany by the *Länder* (states), the creation of a framework law could only be a first step. Such a law might encourage the establishment of regional cancer registries similar to those in Britain. West Germany has only two such registries now, in Saarland and in Hamburg.

Even though mandatory registration of cancer cases is forbidden by strict privacy laws in West Germany, Dhom said that the Saarland cancer registry has functioned well with voluntary participation by doctors. Doctors submit data together with the identification of cancer patients to the registry, which removes the names to protect the patients' privacy.

But he criticized as "expensive and technically difficult" the method chosen for a new registry in Baden-Württemberg. There, data are made anonymous before being reported to the central registry; Dohm predicted that double entries will become a major problem. The main reason this method was adopted, he said, was to please data protection activists who fear meddling by the state. But Dhom said that cancer patients in West Germany are in favour of more cancer registries and that opponents have succeeded in preventing their creation by using "very irrational" arguments. **Steven Dickman**

UNIFIED GERMANY

Money, money, money

Munich

THE West German science council Wissenschaftsrat on 11 July called for massive aid for teaching and research in what is now East Germany in order to raise standards and make its universities more attractive to students and professors. At least DM6,500 million (about $4,000 million) will be needed by 1995, exclusive of running costs, said the council.

Good research and advanced study should be moved back from the East German Academy of Sciences to "diverse and properly functioning" East German universities, according to the council.

One way to do this, it suggested, is to remove from the academy the right of granting advanced degrees and teaching qualifications (*Habilitation*).

The council urged East German institutions and Western reviewers to resist the pressure simply to impose the West German system on East Germany. Instead, West Germany should take the opportunity to identify its own weaknesses and correct them.

The council also supported an increase of at least 25 per cent in the budgets of the Alexander von Humboldt Foundation and the German Academic Exchange Service (DAAD) to promote the international exchange of senior and junior researchers as well as students in a united Germany. **S.D.**

NAZI VICTIMS

Graves desecrated

Munich

UNKNOWN persons on 15 July desecrated the graves where body parts and tissue samples taken from the corpses of Nazi victims had been buried 11 days earlier. The samples had been in the collections of the University of Tübingen and were used for research and teaching purposes until a scandal in 1989 prompted their removal and eventual burial.

The criminals spray-painted swastikas onto the gravestones in the Tübingen city cemetery and hacked to pieces the stone that commemorated the victims.

The University of Tübingen held a commemorative ceremony on 8 July in honour of some 400 people whose remains were discovered in the collections of the Anatomy Institute. At the recommendation of an external committee, the university removed from the collections the remains of anyone who was known or even suspected to have been killed by the Nazi regime.

The destroyed stone was carved with a motto written by University of Tübingen pathologist Jürgen Peiffer: "Abducted, oppressed, violated,/Victims of despotism or blinded justice,/People did not find their rest until they arrived here./From their corpses even,/was demanded a service,/by a science that did not respect human values and dignity. /May this stone serve as a warning to the living." S.D.

RADIATION HAZARDS

Data released at last

Washington

THE controversy over whether exposure to low-level radiation is linked to an increase in cancer deaths looks set to be refuelled after the US Department of Energy (DOE) last week finally released data on the radiation exposure and mortality rates of workers at nuclear weapons plants. The data are being released to the Three Mile Island Public Health Group which disputes the the official DOE opinion that low levels of radiation are safe because at worst they are linked only to one very rare form of cancer. DOE officials have until now been reticent to release their data, claiming that information on workers' health is confidential.

Success for TMI in a three-year lawsuit came only after pressure from Congress and the recommendation of a DOE panel of enquiry that public access be given to workers' health statistics.

This first installment of newly released data includes records of the radiation exposure and mortality rates of 44,000 people who worked at the DOE's Hanford Facility in Washington between the 1940s and 1981. Hanford is the DOE's oldest nuclear weapons manufacturing plant.

TMI will eventually have access to data on 200,000 workers, one-third of all of DOE 's personnel. But the terms of the legal agreement between TMI and DOE prevent TMI from releasing this information outside their research team.

With the new data, the 83-year-old TMI epidemiologist Alice Stewart hopes to update her earlier controversial studies with the Hanford population of workers. Her work was stopped in 1977 when her supervisor, Thomas Mancuso, lost his contract with DOE. That decision was in itself the subject of a congressional hearing.

Mancuso and his co-workers had published a study suggesting that increases in many kinds of common cancer could be seen at levels of radiation exposure that DOE considered safe.

Rival epidemiologists, including those under contract with the DOE and independent groups in British and Canada, dispute this finding. According to DOE contract researcher Ethel Gilbert of Battelle Pacific Northwest Laboratory, they have found only suggestions of a correlation between low-level radiation exposure and the ocurrence of multiple myeloma, a very rare cancer, in the DOE worker population. Data collected in Japan from studies of A-Bomb survivors do not support Stewart and Mancuso's conclusions.

DOE officials are currently considering how they will make data on all their workers available to the public. **Robin Eisner**

COMPUTER INDUSTRY

Fujitsu's long march

London & Tokyo

Fujitsu, Japan's largest computer maker, is to bid for a majority shareholding in ICL, the only British company still manufacturing mainframe computers. News of the deal, leaked to the press two weeks ahead of the planned announcement, has sent a shockwave through the computer industry as it is seen as the most daring of a series of moves by Japanese companies determined to build global competitors to the US giant, IBM.

If successful, the bid will take Fujitsu from the number four position, in terms of global revenues, to the number two position, leapfrogging NEC of Japan and Digital Equipment Corporation of the United States. But Fujitsu and ICL's combined revenues for 1989 were still less than a quarter that of IBM.

Fujitsu is expected to bid for at least a 50 per cent holding in ICL at the end of this month. The Japanese company would gain a profitable subsiduary (ICL had pre-tax profits of £145.7 million last year) and easy access to the computer market in the European Communities (EC), when trading restrictions between the EC partners are abolished in 1992. Some link up between the two companies had been expected, since Fujitsu already supplies ICL with semiconductors for its machines. But few predicted that STC, ICL's parent company, would be prepared to give up a majority stake.

Fujitsu's takeover bid is just one of several moves by Japanese computer manufacturers intended to form alliances against IBM with European and US companies. European companies are not themselves seen as serious competitors; with the backing of the Ministry of International Trade and Industry (MITI), Japanese companies are concentrating single-mindedly on overtaking IBM.

Apart from its ICL link, Fujitsu has a major shareholding (43.6 per cent) and cooperative marketing agreement with the US computer maker Amdahl, which uses Fujitsu technology in its computers. The Japanese company also has an agreement with Siemens of West Germany, whereby Siemens sells Fujitsu computers with Siemens labels on them.

Hitachi and NEC have gone into similar licensing agreements and joint ventures in Europe, producing a marketing network for Japanese companies that in total matches IBM's in scale.

UK Opposition Labour party technology spokesman Lewis Moonie says he is "disappointed that the only remaining British mainframe manufacturer has to pass into foreign hands". He blames the lack of a coherent government strategy for information technology for the current state of the British computer industry, and is also concerned about the takeover of the UK software company Hoskyns by the French group Cap Gemini Sogeti, announced last week.

But Martin Campbell-Kelly, who lectures in the history of the computer industry at the University of Warwick, does not view the ICL takeover as the death knell for the British computer industry. Rather, he says, the industry has moved on from the manufacture of hardware to the production of integrated computer systems assembled from hardware manufactured elsewhere.

Campbell-Kelly says that two important questions surrounding the ICL deal remain unanswered. The first is whether Fujitsu will discontinue ICL's mainframe range to concentrate on marketing their own products. The second is what will happen to ICL's research and development base once the company passes into Japanese hands.

Some UK observers predict a diminution of research, but Japanese electronic companies typically re-direct large percentages of their profits into research and development, suggesting that Fujitsu will make full use of ICL's research capabilities. Several Japanese computer manufacturers have already set up research units in Europe and the United States.

Peter Aldhous & David Swinbanks

OCEAN RESEARCH

Japan dreams deep dreams

Tokyo

Japan's ambitions to have the biggest and the best of everything appear to have touched the Ocean Development Division of the Science and Technology Agency, which last week sent in a request for funds to begin work on the design of the world's largest ocean drilling ship.

The initial request is for just ¥97 million ($620,000). But the design is to be for a ship of 18,000 tons (gross) — more than twice the size of the US ship *JOIDES Resolution* which is used in the International Ocean Drilling Program. Yoshiro Miki, director of the Ocean Development Division, says the ship would be equipped with all the most sophisticated Japanese instruments, would cost about ¥30,000–¥40,000 million ($200–$270 million) and would be ready before the end of the decade.

The International Ocean Drilling Program is scheduled to end in 1993. But it may be extended by another five years or so, in which case the Science and Technology Agency will discuss how to share the drilling activities of the two ships with the countries involved in the programme.

Somewhat surprisingly, the Ministry of Education, Science and Culture, which at present supports Japan's participation in International Ocean Drilling Program, has not expressed any opposition to the Science and Technology Agency's plans. The two organizations often fight for territory in basic research but Miki says ocean research is one area in which they have learned to collaborate.

The only thing that might thwart the agency plans to build the drilling ship is the Science and Technology Agency's commitments to space research. The agency's participation in the US space station project will drain its resources over the next decade. But Miki and other agency officials are determined to try to maintain a well-balanced budget for all areas of scientific research.

The Ocean Development Division has other new projects, besides the drilling ship, which it hopes to cover with a total 24 per cent increase in its budget for next year. The budget request, for ¥12,000 million ($80 million), will almost certainly be whittled down by the Ministry of Finance over the coming weeks but is in line with recommendations published by the Council for Ocean Development of the Prime Minister's Office in May and a call for increased research on Earth science and technology issued last month by Japan's highest science policy-making body, the Council for Science and Technology. Miki says he is confident that the new projects will be funded.

Biggest among them is the DEEP STAR (Deep-sea Environmental Exploration Program-Science and Technology for Advanced Research) project, which aims at growing deep-sea microorganisms in the laboratory at pressures up to 650 atmospheres (the pressure at a depth of about 6,500 metres in the ocean). The project began this financial year with a budget of ¥790 million ($5.2 million) to build equipment for collecting microorganisms from the sea floor. A total investment of about ¥4,500 million ($30 million) will be required over three years to complete facilities on land, Miki says.

Koki Horikoshi of the Institute of Physical and Chemical Research (RIKEN), who won international recognition for his 'Superbug' project (see *Nature* **310**, 172; 1984), will head the DEEP STAR project at the Japan Marine Science and Technology Center (JAMSTEC).

The budget request also includes several hundred million yen to study ocean circulation and climate change near the North Pole in collaboration with the United States and West Germany.

David Swinbanks

ANIMAL RESEARCH

Battle lines are drawn

Washington

UNDER pressure from both animal welfare groups and scientists, two groups with widely divergent views of how the government should regulate the use of research animals, the US Department of Agriculture (USDA) last week opted for a compromise; it issued comprehensive new rules on the care of guinea-pigs, hamsters and rabbits, but inserted language to ensure that few laboratories will be forced to buy new cages or make other expensive changes to conform.

The new rules are the first of two controversial sets of regulations to make it all the way through the regulatory process and to be published in the *Federal Register*. Both have been the subject of a five-year struggle between the agency, Congress and activists. As such, the battle over them has been mostly one of principle; the guinea-pig and rabbit regulations are seen as a precedent-setter for the still-unresolved and much more contentious regulations for non-human primates and dogs (see *Nature* **345**, 755; 28 June 1990).

At issue is the concept of "performance-based" versus "engineering" regulations. Scientists argue that they should be given some leeway to design animal caging that does not exactly conform to some minimum size standard as long as they can show that the animals are healthy and happy. Animal welfare lobbyists, on the other hand, say such performance-based regulations are unenforceable, and that anything other than strict size standards are no standards at all. The Animal Legal Defense Fund, which has sued USDA to release the primate and dogs rules, is considering a lawsuit over the guinea-pig and rabbit regulations as well.

Although the new guinea-pig and rabbit regulations lay out strict cage-size minimums, they are "grandfathered" — they apply only to new caging bought after the rules take effect next month. More importantly, the rules allow an exemption for "innovative enclosures that do not precisely meet the space requirements". What that means is that good cages are not necessarily standard boxes, says John Miller who, as director of the animal welfare office of the National Institutes of Health (NIH), helped to write the new regulations. Because, for example, hamsters prefer walls to open spaces, if one were to design a hamster cage that was a series of interconnected tubes, which maximize the wall area but may not quite meet the minimum floor space requirement, the enclosure would still be perfectly acceptable, Miller says.

"That's precisely why the 'innovative enclosures' clause was inserted — to give the regulations that performance flavour". Miller explains. But he stresses that the clause does not offer *carte blanche* for scientists to ignore the size standards. "Smaller than minimum does not constitute innovative", he says. At any rate, because the new regulations put into law the NIH guidelines that have been in place since 1972, almost all NIH-funded animal laboratories are already in conformance, Miller says.

The still-unfinished rules for primates and dogs are now likely to also include an similar "innovative enclosure" clause, according to Miller. Since the White House rejected the USDA's previously proposed engineering-based standards earlier this year (see *Nature* **344**, 804; 26 April 1990), the agency has retreated to lick its wounds and rewrite the regulations in performance-based language. It intends to resubmit them for review and public comment this fall.

G. Christopher Anderson

US SPACE PROGRAMME

Stone voyages to JPL

Washington

VOYAGER 2, the phenomenally successful interplanetary probe whose flyby of Neptune last year provided a much-needed boost to the National Aeronautics and Space Administration (NASA) space programme, has left yet another success in its wake. Edward Stone, Voyager's scientific director, has been selected as the next head of NASA's top planetary and robotics facility, the Jet Propulsion Laboratory (JPL). Stone will replace Lew Allen, who is retiring in December.

Stone will be taking over a laboratory that has seen much of its original robotics mission eroded by an increasing NASA emphasis towards manned space exploration. He says that broadening JPL's base beyond planetary science — a process already begun by Allen — will remain a top priority. Likely areas of growth include work on parallel-processor supercomputer, radiation-hardened electronics, robotics and instrument-building for other NASA laboratories. Further changes at JPL — including a possible increased emphasis on missions focusing on cosmic particles and fields, Stone's scientific specialty — may be some time off.

JPL's development over the next two years has already been set and any new direction at the laboratory will have to wait, Stone says.

FRENCH BUDGET

Research still in favou

Paris

**THE French government has once agai
made education and research top prioriti
in its annual budget. Although ministe
have been told only the global figures th
can expect — it is up to them to propo
how the money should be spent — educ
tion is set to receive 9 per cent more th
last year and research and technology
increase of 7.5 per cent. Inflation in Fran
is currently 2.5 per cent.**

**The national education budget, whi
includes university research, but not oth
state research money, will increase
FF20,000 million ($3,610 million)
FF250,000 million. The increase will
swallowed up by a major new constructi
drive within higher education and am
tions to create thousands of new posts in
sectors of education.**

**Unlike most of its neighbours, Fran
will not decrease its defence budget ne
year. Jean-Pierre Chevènement, the defen
minister, has apparently succeeded
fighting off proposals to cut his budget a
has even won a 3 per cent increase, ju
ahead of inflation. But greener issues a
still close to President François Mitterrand
heart: the environment ministry will see i
budget up by 15 per cent in 1991.**

**Ministers and civil servants now have t
summer to prepare detailed budgets in tin
for a cabinet meeting in September.**

Peter Col

UK RESHUFFLE

New minister for old

London

**ROBERT Jackson, UK minister for scien
and higher education, has been mov
from the Department of Education a
Science (DES), as part of a reshuffle
middle-ranking ministers designed
improve the Conservative government
image and performance in the run up to t
next general election. Jackson had be
widely criticized for his piloting throu
parliament of a bill introducing loans f
students, and the failure to convince t
major banks that they should administ
the scheme. More recently, he was attack
by colleagues after joking at London
Heathrow airport that his ministerial b
contained a bomb.**

**Michael Fallon, newly appointed to t
DES, is expected to take over Jackson
responsibilities. The British scientific co
munity will hope that Fallon's appoin
ment introduces a more sympathetic att
tude from the DES towards the need f
increased funding and improved care
prospects in UK science. Jackson h
maintained that the UK 'brain drain' is
myth, and was labelled "the rottweiler
academia" at recent press conference
the pressure group British Scientis
Abroad.**

Peter Aldho

HUMAN GENOME PROJECT

The honeymoon is over

Washington

AFTER an infancy of accolades from politicians and scientists alike, the Human Genome Project is finding that growing up is hard. The House of Representatives Appropriations Committee last week cut the project's 1991 funding to $66 million — nearly $34 million less than the president's request, which was itself $24 million less than genome project officials had originally asked for. Overall, the House figure is about one-half of what genome project planners had hoped for next year and reflects a substantial erosion of confidence in the project among legislators.

House Appropriations Committee staff say they are concerned that the project, which is orientated toward centres rather than individual grants, would contribute to the trend at the National Institutes of Health (NIH) away from support of single investigators. They also say that project officials have made a poor case for their budget request, by providing detailed numbers only when asked and by lifting much of the request from the recommendations of a 1988 National Academy of Sciences report.

Staff say that although a letter-writing campaign by scientists opposing the project was not a major factor in the House decision, appeals from other researchers in support of more individual-investigator grants were persuasive.

NIH genome centre director James Watson says the House has missed the point. "I think they've misunderstood the role of centres in the project", he says. Much of the sequencing and mapping of the project is routine work best suited to a small number of well equipped laboratories. Although fundamental research is often well suited to small laboratories and single researchers, the genome project requires something closer to factories. "Congress needs to make the distinction between exploratory research and getting the job done", Watson says.

Legislators on the Senate Appropriations Committee side with Watson on the initiative. But although they say they will try to vote the president's full $108 million request, the vagaries of the budget process have left the committee with nearly $2,300 million less for NIH as a whole, and it may be forced to make cuts as well.

Once the Senate has arrived at a figure, the two arms of Congress will negotiate a compromise budget in conference. Short of a catastrophic across-the-board cut to satisfy the Gramm–Rudman deficit-reduction provisions, the genome project is likely to get something between the House and Senate figures and far less than the president's request.

Officials at the genome project's NIH headquarters are not counting on a substantial reprieve. Three new projects that were about to be announced — a new pilot sequencing programme, a mapping database and a project to locate index markers on the genome — are now in abeyance until the picture clears, says genome office budget officer Erin Burgess. NIH had also planned to start nine new centres at about $4 million each in 1991; the House cuts could lower that to as little as three centres at $2–$2.5 million each.

Funding for the three projects now in limbo was to have amounted to about $19 million next year — just a little more than the $18 million that Congress has placed tantalizingly out of reach in a special discretionary fund for the director of the NIH. This fund can be made available to the genome project at the discretion of the NIH director, once a director has been appointed. There has already been a delay of nearly a year in filling the position, which has caused increasing tension between NIH and Congress. House staff say that they want a new director soon, and they want that director to take a new look at the progress and management of the genome project.

Genome centre officials fear that linking the genome centre's fortunes to the arrival of a new NIH director places the project's growth in jeopardy. "We're not feeling very positive about the money. We're hoping the Senate will say you can't hold the genome project hostage for a new director", says Burgess.

The Department of Energy (DOE), which runs about one-third of the project, has so far done much better in the appropriations sweepstakes. DOE funding from the House is $46 million, just what the president requested.

G. Christopher Anderson

ABORTION PILL

French pill for Britain?

Paris & London

RU-486, the abortifacient pill, could be marketed in Britain by next year if its manufacturer, the French company Roussel-Uclaf, goes ahead with its decision to apply for a product licence. At present, says the company's head of marketing, Ariel Mouttet, Roussel-Uclaf is making enquiries to ensure that the strict controls surrounding distribution of RU-486 in France can be maintained in Britain. If so, the company will send its application to the Department of Health.

At present, RU-486 is only available in France. Even there, it took state intervention to put the drug back on the market after it was withdrawn following threats to company executives from anti-abortion groups (see *Nature* **340**, 6; 1989). Only now, after successful clinical trials in Britain and over two years of use in France, is Roussel-Uclaf preparing its first major attempt to market the drug abroad.

The drug already has some supporters in British medical circles and, according to Mouttet, Kenneth Clarke, the health secretary, has written to encourage Roussel-Uclaf to apply for British registration. Naren Patel, honorary secretary of the Royal College of Obstetricians and Gynaecologists, says that "preliminary reports seem very favourable", although he stresses that he has not yet seen all the data on clinical trials. Patel believes that the drug may be more appropriate for certain terminations than existing techniques. A spokeswoman for the British Medical Association was also supportive. "We do not see any immediate medical problems", she said. But she pointed out that abortions still require the consent of two doctors, under the terms of both the old Abortion Act and the Human Fertilization and Embryology Bill, currently before parliament.

Roussel-Uclaf is also keen to dispel any ideas that RU-486 will be available over the counter as a 'morning after' pill or for 'do-it-yourself' abortions. In France the drug is available only within approved clinics and hospitals and must be taken in the presence of a doctor, in association with synthetic prostaglandins.

Mouttet explained that the company will not proceed with its application unless tight distribution controls are respected. In France the drug is treated in the same way as are opiates and controlled narcotics. At pharmacies it must be kept in a locked cupboard and a complex system of numbered order books, consent forms and sticky labels ensures that every box of the drug can be accounted for.

An estimated 40,000 women have now aborted using RU-486 and Roussel-Uclaf has full records on 20,000 of them. A study of the first 2,000 cases has been published and a report on a further 10,000 women is available within Roussel-Uclaf. Until March this year, the drug was issued free and, says Mouttet, orders were running at "about 4,000 boxes per month". Now there is a charge, demand has dropped to "about 3,000 a month".

If RU-486 is marketed in Britain, the manufacturers will next consider approaching Scandinavian countries. But Mouttet confirmed that the company still has no plans to market RU-486 in the United States or to carry out clinical trials there. If the drug is easily available in Britain, however, a black market for the drug might easily develop in the United States.

Peter Coles & Peter Aldhous

Send Hubble to the Moon

SIR—The proposal of Bahcall in *Nature* of 22 June last year[1] to establish an international institute for astrophysics is an important one. In particular, their suggestion of taking to geosynchronous orbit the 2.5-metre test mirror developed for the Hubble Space Telescope (HST) programme is an interesting possibility.

This is an example of reducing astronomical costs as well as sharing them. In low Earth orbit, the HST must be serviced during the next solar cycle, which may be a costly exercise, possibly compromised by the flight availability of the Space Shuttle. In geosynchronous orbit, on the other hand, an HST instrument would need less servicing, and would provide direct data access (see ref. 2 for a discussion of 90-minute operations). It would have direct command and control, three times the efficiency of observations, and ambient-cooled optics (being further from Earth).

I would like to take this suggestion one step further, and point out that the Hubble test mirror could be taken to the Moon, again as part of a cost-effective strategy. NASA has recently conducted three workshops[3-5] addressing physics and astronomy from the Moon, the first of which contributed to a presidential decision that a return to the Moon would be the next major goal of the US space programme. It is clear that the Moon, as our nearest neighbour, offers distinct advantages for space astronomy over low-Earth orbit and geosynchronous orbit, and over any planetary initiative.

Taking the Hubble test mirror to the Moon, at the onset of the programme, could serve as a focal point for the lunar initiative, placing the programme's emphasis on science and astronomy. In this scenario, the test mirror with modern instrumentation and redesigned actuators for a structural 1/6-gravity environment at a lunar base (rather than zero-gravity in Earth orbit) would be put in place immediately at the landing site on the second or third manned mission to the Moon. (There may be unmanned excursion missions, landing before the manned phase.)

A 10,000-pound Hubble instrument is 4.5 metric tonnes, one of the very payload weights currently used by NASA's Office of Exploration[6] in its preliminary models for the manned flights there. With the approval of the US Congress, one can easily imagine the Hubble 2.5-metre mirror at a man-tended lunar base within this decade (by the year 2000, one of the schedule dates now in use[6]).

The existing proposals[3,5,6] on astronomy from the Moon have been described as "lacking vision". Using the Hubble test mirror in this way, that is, putting it in place at the onset (the second lunar landing) at low cost (as an 'off-the-shelf' instrument) could catch the public imagination and muster the scientific support required for a visionary approach (see H.J. Smith in ref. 5 for discussion). This must not compromise the Hubble programme itself, it must be international in scope, and it must be followed by a more ambitious set of observatories using larger, higher-quality mirrors (since the Hubble test mirror does not meet the needs of space astronomy in the twenty-first century).

The Hubble emplacement, early on, would also serve as a testbed for determining requirements and problems for astronomy from the Moon as the initial outpost evolves into a mature lunar base.

Global warming

SIR—Perhaps you have not received any correspondence that presents a positive or optimistic outlook for the changes that are predicted to accompany or be a consequence of global warming? The good news that large areas of Canada and the Soviet Union may become more conducive to agriculture seems largely discounted. More optimistic speculations could centre on how the results of the greenhouse effect might circumvent the burning of fossil fuels for energy. Apart from the argument that we may need to burn less fuel for heating in a warmer world, going further, desert areas could become the 'oil wealth' of the future if they were turned over to massive-scale production of solar-generated electricity. This abundant electricity might be used to make hydrogen for use in internal combustion engines. Or perhaps there could be solar-powered desalination plants to produce fresh water for use in, say, irrigation programmes. Such schemes would require labour, but might appeal to people forced to move if their homes became uninhabitable as a result of climatic change.

Such an optimistic outcome would, of course, require planning, management and co-operation between nations on an unprecedented scale. Such intergovernmental co-operation may seem unlikely, but an unbalanced, gloomy outlook surely cannot help it to come about. I hope you will encourage the avoidance of doomsaying in such matters.

Australia prize

SIR—Tania Ewing's story on the Australia Prize (*Nature* **344**, 692; 1990) need correction.

Professor Allen Kerr did not isolate the bacterium responsible for crown gal disease. That was done long ago. He was however, the first to show that pathogenicity in *Agrobacterium tumefaciens* could be transferred from one strain to another.

This transfer was then shown by the groups associated with Professors Eugene Nester and Jeff Schell to involve the large tumour-inducing plasmid (pTi). This was the beginning of the development of an effective plant transformation system, to which their groups have contributed so many advances.

Ewing errs again in attributing to them the genetic engineering of a benign strain of *Agrobacterium* to ensure continuing effectiveness of the system of biological control of crown gall disease. That was due entirely to Kerr's group.

Crisis in education

SIR—It seems that there is a dearth of applications for postgraduate research awards this year, but there is a widespread reluctance on the part of supervisors to admit how few applications have been received for the awards on offer, as they fear that the poor application rate will discourage funding bodies from continuing their support.

This is a mistake. Rather than concealing the situation, we should be shouting and screaming about the low number of aspiring postgraduates, as it is symptomatic not of problems within individual departments, but of a major crisis within the whole higher education system that must be addressed now. A dearth of postgraduates now will be a constraint on the future development of research in this country.

PHARMACIA LKB ACADEMY OF BIOMOLECULE MANAGEMENT

Pharmacia LKB puts its customers in a class of their own.

Last year, Pharmacia LKB planned, organized and ran an impressive educational programme of workshops, seminars and symposia at laboratories and institutes around the world. The purpose of these programmes, which we run every year, is to pass on to our customers the skills and knowledge they need to solve their own separation problems. And show them how to get the most out of our comprehensive and ever-growing range of products for biomolecule management.

In the past 30 years, we've worked closely with researchers in almost every field of bioscience; while we helped them with their separation problems, they helped us to develop and perfect our products. At the same time, we've amassed a wealth of specialist knowledge in separation technology, both theoretical and practical. It's the kind of knowledge that could help you solve some of your research problems. And it's yours for the asking.

Our 1990 calendar of events is well underway and we're already planning for 1991. There will be courses covering everything from basic liquid chromatography, electrophoresis and industrial scale to advanced separation and molecular biology techniques. If you'd like to take part or simply want to know more about the programme we're running near you, talk to your Pharmacia LKB representative today.

It'll be an education.

We help you manage biomolecules.

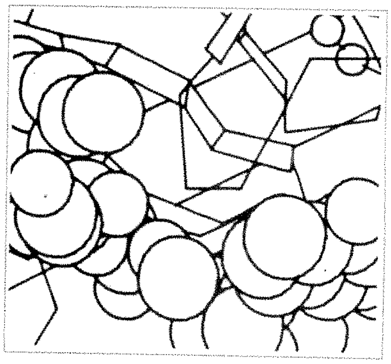
NEW Books from Macmillan

TOPICS IN MOLECULAR AND STRUCTURAL BIOLOGY



Series Editors Watson Fuller and Stephen Neidle

This series provides researchers in the biological and medical sciences with timely reviews of selected areas in molecular biology. These reviews emphasise the role of physical and chemical techniques in providing an understanding of biological function in terms of three-dimensional molecular structure. Each volume is edited by an internationally recognised authority who selects authors and topics to provide a survey of current growth points in a specific field.

Protein-Nucleic Acid Interaction

Edited by W Saenger and U Heinemann, Institut Fur Kristallographie, Freie Universitat Berlin, FR Germany

The rapidly developing field of protein-nucleic acid interactions is highlighted in eight chapters describing the use of modern techniques in the study of large and small model systems.

July 1989 Hardback £40.00
234 x 156mm 224pp 0-333-45321-2

Calcified Tissue

Edited by David W L Hukins, Department of Medical Biophysics, University of Manchester, UK

This book emphasises aspects of calcification which are important to humans and presents aspects of current research, notably attempts to relate biological function to the structures and interactions.

October 1989 £50.00 234 x 156mm
262pp 0-333-45320-4

Oligodeoxynucleotides

Edited by Jack Cohen, Head of the Biophysical Pharmacology Division of the National Cancer Institute, Bethesda, USA

The first-ever book on oligodeoxynucleotides describes in detail the latest research developments in the new antisense approach to chemotherapy.

December 1989 £55.00
234 x 156mm 272pp 0-333-49211-0

Molecular Mechanisms in Muscular Contraction

Edited by John M Squire, The Blackett Laboratory, Imperial College, London, UK

A turning point in muscle research. This book reviews the evidence that myosin cross-bridges do indeed swing on actin filaments during contraction, and starts to tackle the problems this raises: what are the geometrics of the attached states of cross-bridges on actin? How many states are there? What is the sequence of molecular events during muscle activation? And is the primary source of muscular force cross-bridge swinging or Helix-coil transition?

January 1990 £55.00
234 x 156mm 350pp 0-333-45155-4

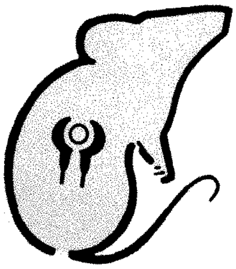
NATURE'S 1990 CONFERENCE



NEW HORIZONS IN IMMUNOLOGY

15–16 November 1990
Boston, at the Copley Plaza Hotel

CONFERENCE SESSIONS

1. TOLERANCE AND THE IMMUNE REPERTOIRE

John Kappler (Denver)
Philippa Marrack (Denver)
Ronald Schwartz (NIH)
Christopher Goodnow (Stanford)
Susumu Tonegawa (MIT)

2. ANTIGEN PROCESSING AND PRESENTATION

Jack Strominger (Harvard)
Don Wiley (Harvard)
Alain Townsend (Oxford)
Emil Unanue (U. Washington St Louis)

3. AUTOIMMUNITY AND CONTROL OF IMMUNE RESPONSE

Hugh McDevitt (Stanford)
Leroy Hood (Caltech)
Lawrence Steinman (Stanford)
Jacques Miller (Melbourne)
Irun Cohen (Weizmann Inst.)

4. VACCINES AND ANTIBODIES

César Milstein (MRC Cambridge)
Greg Winter (MRC Cambridge)
Jay Berzofsky (NIH)
William Paul (NIH)

Commentators: Charles Janeway (Yale)
Polly Matzinger (NIH)

BOOK BEFORE 31 AUGUST TO SAVE $75

- Understanding at the molecular level of immune recognition has provided new insight into fundamental mechanisms of immunity and new approaches to immunopathology and therapy.
- Identification of potentially self-reactive receptors on T lymphocytes has led, through the use of transgenic mice, to an understanding of natural mechanisms of immune tolerance.
- Specific T-cell receptors may be associated with autoimmune disease and may offer a new target for therapy.
- New ways of defining immunogenic antigens have emerged from the structure of HLA, and have stimulated new approaches to the design of vaccines.
- Definition of the interleukins that invoke immunoglobulin E responses suggest new targets for the treatment of allergy.
- "Humanized" antibodies promise new approaches to tumour therapy.

Many new questions arise. Do some HLA alleles confer resistance to autoimmune disease by causing the deletion of specific T cells during the normal induction of tolerance? What part does antigen processing play in determining immune responsiveness? Can the "superantigens" that cause toxic shock help to explain how each individual's unique T-cell receptor repertoire is selected during development? How can engineered antibodies out-smart evolution in the generation of magic bullets against disease? To explore these questions and explain the most recent advances, leading researchers have been invited to speak on the basic science and its therapeutic implications, with organized discussions led by invited commentators.

We expect the conference to sell out well before opening, so urge you to make sure of your place now by returning the form below. TO SAVE $75 BOOK BEFORE 31 AUGUST

NEW HORIZONS IN IMMUNOLOGY: 15–16 November 1990

REGISTRATION FEES
Standard rate including reception
$275 before 31 Aug 1990
$350 after 31 Aug 1990
Special rate for full-time academics and government employees only
$225 before 31 Aug 1990
$300 after 31 Aug 1990

Sponsor's liability: should the conference be cancelled or postponed for any reason, the sponsor's liability is limited to the return of the registration fee. Cancellation policy: all cancellations must be received in writing. Cancellations before 30 August will be subject to $25 service charge. No refunds will be made after that date. Registrants unable to attend may send a substitute.

AuroProbe LM The label of choice in light microscopy

AuroProbe LM and IntenSE M — an excellent, top quality marker system for the detection of specific antibodies against cell or tissue components using the light microscope.

- **Simple and sensitive**
Ready-to-use reagents make immunostaining very straightforward. As sensitive as immunofluorescence[1,2]

- **Choose your own counterstain**
Allows simultaneous immunolabelling and morphological evaluation of the same preparation.

- **Unequivocal detection**
Highly localized signal that does not fade and the additional use of epipolarization* offers immunostaining of unparalleled clarity.

- **Double immunolabelling**
Gold probes can be used in combination with fluorochrome conjugates or enzyme labelled antibodies.

Contact your local Amersham office for more information.

Can mirrors beat the greenhouse?

People should not personally assume responsibility for the greenhouse effect, which would be impossible, but they should give some thought to the quantities involved.

AMONG the green community, the prospect that the excess greenhouse effect may be a reality, even here and now, has evoked a general wish to be seen to be doing something to assist in its abatement. That is natural enough, even though there are the strongest possible reasons for suspecting that individual virtue will serve only to provide the less virtuous with a licence not to follow suit, which is why the proper regulation of the greenhouse requires an international convention. Meanwhile, a child's guide to some of the steps that individuals might take may also serve as a guide to the underlying simple arithmetic.

At the present average distance between the Sun and the Earth, the solar energy flux normal to the line of sight is roughly 1,370 W m^{-2}, but only some 70 per cent of that reaches the surface of the Earth. (Ultraviolet is mostly absorbed by the ozone layer, which is mostly still there, radio waves are screened out by the ionosphere and so on.) The average sub-zenith solar flux may be taken as 950 W m^{-2}, not very different from 1 kW m^{-2}, but that is only ever nearly valid in the tropics, while half of the surface of the Earth is always turned away from the Sun; the average flux at the surface is therefore one quarter of the sub-zenith flux, say 240 W m^{-2}.

It is important that the mismatch between incoming and outgoing radiation fluxes expected from the accumulation of CO_2 and other greenhouse gases is of the order of 1 W m^{-2}. This, for example, is the degree of what is called in the trade the 'forcing' of the Earth's climate system caused by the accumulation of CO_2 and, to a lesser extent, of methane, between 1850 and 1960 — then the only greenhouse gases worth talking of. (CFCs have become a serious contributor to the problem only since that time.) People bent on personal steps to ameliorate the excess greenhouse effect must keep that figure in mind. What can they do?

First, perhaps, they should consider what might be done with simple mirrors. If one happened to live in the tropics, one might hope that a square metre of silvered glass placed in one's back garden would reflect back to space a substantial fraction of the incident flux of energy — perhaps not the whole of 1 kW, but roughly a quarter of it. But even that is not quite true. When the mirror surface is away from the sub-zenith point, the absorption and scattering of energy on the longer pathways into and out of the atmosphere will be greater. Perhaps the most one can hope for is that an eighth of 1 kW m^{-2} will on the average be turned away.

Naturally it is worse when, like most people, one lives outside the tropics. Then there is an extra factor of cos α (where α is latitude) to be taken account of, as well as the extra absorption and scattering in the atmosphere. At latitude 60°, that means a further factor of two on account of latitude, and yet another factor of two on account of extra path length through the atmosphere. If the albedo of the part of the surface on which the silvered mirror is placed is that of a perfectly absorbing black body (which cannot be exactly true), a single square metre of silvered surface will turn back only an average of roughly 30 W. Carpeting a few per cent of the Earth's surface with mirrors would be necessary to counteract the greenhouse forcing so far (which emphasizes why snow cover and sea ice are important in climate models). But an area smaller by a factor of about four would be required in the tropics.

Absolute quantities are important at this stage. In round numbers, the surface area of the Earth (two-thirds of which is water) is 5×10^{14} m^2, which means that the greenhouse forcing of the past 150 years is the equivalent of 5×10^5 GW of energy — not very different from the world's present production of electricity.

Even if one takes the view that one's personal responsibility is limited to one's fair share, it would still be necessary, if repairing past damage is the goal, to be personally responsible for returning to space the equivalent of 100 kW of solar energy, requiring an investment in some 3,000 m^2 of mirror surface outside the tropics or in something like 750 m^2 in the Sahara. If, on the other hand, one took the view that it would suffice to neutralize by mirrors one's incremental contribution to the excess greenhouse effect, then because the next fifty years are expected to be about as damaging as the past 150 it would suffice to lay 150 m^2 of one's non-tropical back garden with mirror surface every year, or to arrange that an agent acting on one's behalf in the Sahara similarly treats 20 m^2 or so of desert surface every year.

This argument is a *reductio ad absurdum*, and is meant to be. (Most people do not have back gardens that big, in any case.) But the orders of magnitude are important. The calculated imbalance between the incoming and the outgoing radiation is of the order of a few kW per person now alive. It must surely be relevant that most of the 5×10^9 of us do not have the opportunity to consume that much electricity.

The opportunity for a technical fix arises at this point. The green community naturally abhors technical fixes, often on the grounds that they are palliatives rather than permanent 'solutions', but it should not go unremarked that the most economical solution of the greenhouse problem by means of mirrors must be that lightweight mirrors, no doubt made of aluminium foil, should be installed in the line of sight between here and the Sun.

No doubt there would be countless opportunities for endlessly more sophisticated calculations of the effects of radiation pressure on such structures. There have already been several calculations in the past of how such devices might be used to channel solar energy towards collecting stations on the surface of the Earth. Faced with the contemporary version of the problem — how best to get rid of solar energy — the space research community would no doubt be able to rise to the challenge.

That is why the true essence of the greenhouse problem is not the question of whether the concentration of CO_2 in the atmosphere is increasing (it is), or that of the degree to which CFCs are more important as greenhouse gases than CO_2, but that of how the accumulation of these materials in the atmosphere will affect the average temperature on the surface of the Earth and then, more subtly, the climate.

So the responsibility falls upon the shoulders of the modellers. What is the coefficent relating CO_2 concentration to the average temperature on the surface of the Earth? The second is evidently a function of the first, and the function is to a first approximation linear, at least when the processes are slow enough, so there must be a number relating one to another. The role of that number is not to tell us whether or not we should be concerned, but to help us to decide whether we should stay awake at nights. But such a challenge is hopelessly premature: the modellers are still at a loss to know what they should do about real clouds as opposed to the 'average cloudiness'.

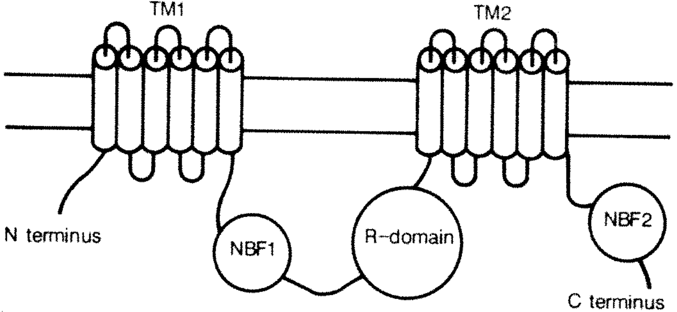
John Maddox

CYSTIC FIBROSIS

A transport problem?

Dagmar Ringe and Gregory A. Petsko

Less than a year ago, the gene responsible for cystic fibrosis, the most prevalent genetic disorder affecting caucasians, was identified and sequenced[1]. As a result, specific sequence changes in genes from affected children can now be correlated with their symptoms. Many of the symptoms of cystic fibrosis are associated with defective transport of chloride ions across epithelia, and Riordan *et al.*[1] initially speculated, among other possibilities, that the gene might encode an epithelial chloride channel. Two papers on pages 362 and 366 of this issue[2,3] reflect recent progress towards a molecular understanding of the disease. Cutting *et al.*[2] have identified four single-point mutations in addition to those already reported in genes from cystic fibrosis patients, and show that all of them cluster in a region of the gene that encodes a putative ATP-binding domain. Hyde *et al.*[3] have attempted to relate genomic defects to altered properties of the protein by proposing a model for this domain, and argue against the hypothesis that the protein functions as a chloride channel.



Schematic model of the cystic fibrosis gene product based on sequence analysis. The segments have been labelled as TM1, TM2 (transmembrane, helical), NBF1, NBF2 (nucleotide-binding domains) and R (unique domain containing the phosphorylation sites). The Phe 508 deletion, the mutation found in 68 per cent of patients, and most of the other mutations observed so far, occur in NBF1. The transmembrane helix mutations occur in TM1.

Cystic fibrosis is an inherited disease characterized by abnormal exocrine secretions, resulting in a devastating variety of symptoms including chronic lung disease. One in every 20 caucasians is a carrier and one in 2,000 live births is affected[4]. The nature of the basic defect leading to the secretory abnormality is unknown.

The gene that is defective in cystic fibrosis encodes a protein of 1,480 amino acid residues (see figure). Hydropathy analysis suggests that the molecule contains 12 transmembrane segments, probably helical, interspersed with three large cytoplasmic domains. The latest reports[2,3] concentrate on two of the cytoplasmic domains, each comprising about 180 amino acid residues. These domains have considerable sequence identity with one another and with similar domains in a superfamily of prokaryotic and eukaryotic transport proteins[5]. The homologous domains contain two consensus sequences that are found in the active sites of proteins that bind and hydrolyse nucleoside triphosphates[6]. The common function of all the previously identified members of the superfamily seems to be the coupling of ATP hydrolysis to the pumping of molecules into or out of the cell.

Cutting *et al.*[2] examined the DNA sequences from exons 9, 10 and 11 and exons 20, 21 and 22 in 38 patients. These exons encode most of the first and second nucleotide-binding domains, respectively. Residue 508 is deleted in the first nucleotide-binding domain in 68 per cent of all patients, but not in these individuals. Four mutations were detected, all in exon 11 in the first nucleotide-binding domain. Three of these mutations cause single amino acid substitutions, and the fourth introduces a stop codon at a position corresponding to Arg 533. Because only a limited region of the gene was analysed, it is not certain that other mutations are present in other exons. Another set of mutations has been reported recently[7]. Patients with these mutations, which occur in the transmembrane regions of the protein, have less severe symptoms. Hyde *et al.* have developed a model for the common nucleotide binding domain in all these ATP-dependent transport proteins[2,8].

The three-dimensional structure of a protein can be predicted on the basis of its sequence if there is a protein of sufficiently similar sequence whose structure is known. Such 'homology modelling' is not possible in the case of the cystic fibrosis product as no structure has been determined for any of the proteins in the superfamily of which it is a member. For this reason, Hyde *et al.* aligned all members of the superfamily and predicted the secondary structure for each sequence. The individual predictions were combined into a consensus secondary structure which showed some similarity to the known pattern of helices and sheets in adenylate kinase. The ATP-binding domain sequences were then folded into a common three-dimensional structure on the basis of the assumed structural similarity with this enzyme.

Given the imprecision of the method used, it is pertinent to ask whether it should be trusted, much less published. The authors admit that the model is likely to be wrong in detail and may even be completely wrong. But it is still a reasonable first attempt and a valuable contribution because it provides a structural model on which experiments can be based, and against which they can be interpreted. Phe 508, for example, is predicted to lie in a loop region with no counterpart in adenylate kinase, so it could lie at an interface between the ATP binding site and the transmembrane regions, where its loss might affect the coupling between ATP hydrolysis and pumping. The amino acid sequence of the 13-residue segment in which all the mutations identified by Cutting *et al.* are found is highly conserved in all members of the superfamily, and the substitutions occur at the three most conserved positions, supporting the assignment of the cystic fibrosis gene product as an ATP-dependent transport protein. In the structural model, these replacements occur in another loop region that is also not found in the adenylate kinase structure, hence the substitutions might not directly affect ATP binding and hydrolysis. But the three missense mutations reported by Cutting *et al.* involve the replacement of small side chains by larger side chains. Site-directed mutagenesis experiments on many proteins have established that such replacements can cause significant alteration in structure if they occur within the hydrophobic core.

Defective transport of chloride ions across epithelia is associated with many of the symptoms of cystic fibrosis[9,10]. But it seems unlikely that the gene product functions as an epithelial chloride channel, despite initial speculations[1]. Hyde *et al.* point out that channels do not require ATP hydrolysis and normally permit the flow of ions in both directions, yet the gene product is homologous with a family of unidirectional active transport proteins. Chloride-channel conductance rates are greater than those of any ATP-dependent transport protein.

Chloride channels appear to differ in different tissues, whereas all cystic fibrosis patients to date seem to have a defect in a single gene. Moreover, the gene product appears too large for an ion channel: its true substrate is likely to be a larger molecule. Finally, ion channels and other transmembrane proteins tend to have characteristic sequence patterns in their intramembrane segments[11]. The pattern of amino acid residues in the 12 putative transmembrane helices does not match the consensus sequences for passive, voltage-gated or ligand-gated ion channels.

Hyde *et al.* argue convincingly that the protein is a transporter but not a chloride channel, but they do not suggest what it transports. It is possible, though, that a function can be proposed based on structural considerations: given the connection between symptoms and the defective regulation of chloride secretion, the protein might transport a molecule that regulates the chloride channel. Mutations could affect chloride secretion by altering the amount of regulator available.

But what is the identity of this molecule? The closest homologues to the cystic fibrosis gene product are the yeast STE6 gene product and the MDR (multi-drug resistance) proteins. Conjugation of hydrophobic drugs to glutathione could be important for *in vivo* export by MDR (ref. 12). Such conjugation has not been observed but the physiological substrates for the MDR proteins have not yet been identified. The substrate for STE6, however, is known to be the farnesyl-derivative of the 12-residue **a**-mating factor peptide[13,14]. The farnesyl moiety is attached by means of a thioether linkage to the C-terminal cysteine of the peptide[15]. From this evidence we can build up a picture of what the substrate molecule for the cystic fibrosis gene product might be like. It would conjugate through a thioether linkage to a glutathione, cysteine or similar residue; it would have a large, hydrophobic organic moiety; and it would have a demonstrable effect on chloride conductance. The products of the arachidonic acid pathway, leukotrienes and prostaglandins, meet these criteria.

Leukotriene LTC4 is known to stimulate mucous and chloride secretion, and has a structure very reminiscent of the farnesylated cysteine of the yeast STE6 substrate. Prostaglandin D2 conjugates with glutathione and cysteine in the presence and absence of the enzyme glutathione S-transferase[16]. Prostaglandin D2 produced the largest change in chloride secretion in experiments with various arachidonic acid metabolites on excised dog tracheal cells[17]. The function *in vivo* of both LTC4 and PDG2 is unclear, but these considerations suggest that one of these molecules (or a similar compound) is the regulator for the epithelial chloride channel and the substrate for the cystic fibrosis gene product. Indeed, an ATP-dependent transporter that pumps glutathione conjugates, including LTC4, from various tissues has already been identified[18]. Inhibition studies imply that this molecule is not identical with the MDR protein[19], but it could still belong to the family that contains MDR, STE6 and the CF gene product. Sequence information about this pump will establish whether the family has yet another member. ☐

Dagmar Ringe and Gregory A. Petsko are in the Departments of Biochemistry and Chemistry and the Rosentiel Basic Medical Sciences Research Center, Brandeis University, Waltham, Massachusetts 02254, USA.

EVOLUTION

Life and times of the guppy

Brian Charlesworth

THE life history of a species or population is described by such variables as the age of first reproduction, and the mortality rate and reproductive success of individuals as functions of age. Life histories vary greatly between taxonomic groups: for example life spans in eutherian mammals range from a few months in small insectivores to 80 years or more in humans[1]. The age of reproductive maturity and number of offspring per litter show a similar diversity[2]. A substantial body of theory has grown up that endeavours to make predictions about the ways in which natural selection moulds life history, and to explain the diversity of life-history patterns[3,4]. A new study on page 357 of this issue[5] puts the standard explanation of life-history differences between natural populations to the test. It is the first case in which life-history differences observed in nature have been reproduced in the laboratory.

Life-history variation between populations of the guppy (*Poecilia reticulata*) are thought to reflect differences in the main species of local predators. In some places, predators take large, adult guppies, but in others the juveniles bear the brunt. Guppies from the former class of population mature earlier, and females allocate a greater proportion of their body mass to the reproductive system and have a larger number of offspring per brood compared with guppies from the second type of population[5]. These differences accord with the predictions of the standard 'reproductive effort' model of life-history evolution[3,4,6]. In species with multiple episodes of reproduction, this model assumes that, for individuals of a given age, the allocation of resources between reproduction and other activities (such as survival to the next time of reproduction) may vary.

Other things being equal, the greater the reproductive effort of an individual (that is, the larger the proportion of resources allocated to reproduction), the lower its chance of survival. The life history that is evolutionarily optimal can be calculated for this model[3,4,6]. One prediction is that the level of reproductive effort favoured by natural selection should be strongly influenced by the relative amounts of mortality of adults and juveniles, imposed by external factors such as predation. Relatively high adult mortality favours the evolution of a life history in which there is high reproductive effort. The intuitive reason for this is clear: if the chance of getting through to the next opportunity for reproduction is inherently low, one might as well reproduce now, rather than get killed off. In addition, relatively high mortality tends to select for genes that increase survival and reproduction early rather than late in life[3].
